The steel market is very firm and prices continue to advance. The mills have practically sold their entire output for the year and are thus in a very strong position. Reports from the steel companies are very optimistic and all indications point to continued activity for the rest of the year. There appears at the present time to be little possibility of any serious weakness developing in the market during the year, but if the market in the United States should decline materially, and some authorities believe that it possibly will do so, then the Canadian market might be affected. There is a feeling that prices are too high and the market for this reason is top heavy. There is, however, no indication that the market has reached the top, but there are signs that prices will probably not go very much higher.

A number of price changes have been made during the week, all in an upward direction. Boiler plates have again advanced, being 25c per 100 pounds higher than last week's quotations. Boiler plates ¼ to ½ in. are now quoted $3.75, heads $4, and tank plates 3-16 in. at $4.10 per 100 pounds. Wrought iron pipe is higher, being the second advance this month. Black pipe has advanced two points and galvanized pipe three points. Cold rolled shafting has advanced and is now quoted at list, plus 10 per cent. f.o.b. warehouse. Steel bars have also advanced and are now

quoted at $3, but iron bars are unchanged at $2.75 per 100 pounds. Toronto warehouse prices on steel bars and shapes are higher, bars being quoted at $3 and shapes at $3.25 per 100 pounds. Prices of boiler tubes are very strong and an advance is looked for in the near future.

The high-speed steel situation is more or less unchanged. Reports from Sheffield, England, state that it is almost impossible to turn out sufficient high-speed steel for munition tools, and that export licenses, more especially to neutral countries are being closely restricted. On account of this heavy demand, comparatively little high-speed tool steel is coming to Canada from England. There is also a big demand in the States for high-speed steel which is tending to keep the prices up and the supplies scarce.

The sheet market is strong with an upward tendency. Sheet bars continue to advance in price, the present level being rather unattractive to sheet mills. There is a big demand for heavy gauges, but the market for lighter gauges is slow. The galvanized sheet market is firm, but unchanged. The uncertain fluctuations in spelter and continued high prices has rendered this market unattractive to most makers.

The steel market in the States is very strong and prices still have an upward tendency. There appears, however, to be an opinion held in some quarters that prices can hardly go much higher and that the top of the market has nearly been reached. The new demand is reported as being very insistent and the pressure on mills for deliveries as strong as ever. Prices of billets are firm and unchanged, but wire rods have advanced to $60 per ton Pittsburgh.

Pig Iron

The pig iron market is firm and the situation unchanged. There is some improvement in the demand for foundry grades of pig iron. Hamilton and Victoria brands are unchanged at $24 per ton.

Old Materials

The market is steady with prices at approximately the same level as last week. Copper and lead are strong and in good demand. Prices on copper are firm and unchanged, but lead has advanced ½c a pound. Heavy melting steel continues in good demand, but quotations are unchanged.

Machine Tools

Business is comparatively quiet, but would be considerably better if machine tools could be obtained when required. Deliveries are so backward on standard tools that dealers are being seriously handicapped in doing business. The demand is still largely for tools for munition plants. Prices on machine tools continue to move toward higher levels. Some makers have made a further advance of 10 per cent. on grinders and engine lathes, whose figures are now approximately 40 per cent. higher than a year ago.

Supplies

Prices of many lines of machine shop supplies continue on the up-grade, a number of changes having been made during the week. Prices of all lines of milled products, such as cap and set screws, nuts, etc., are higher. New and lower discounts have been issued on pipe fittings. The new discount on plate washers is 30 per cent., iron rivets 42½ per cent., bright wood screws 47½ per cent. Soldering coppers have been advanced to 53c per pound base. White lead is now quoted at $13.95 per 100 pounds in ton lots, while red lead is quoted at $13.87 per 100 pounds. Lead wool is 1c higher and is quoted at 13c per pound. The linseed oil market is weaker and prices have declined to 98c for raw and $1.01 for boiled oil, per gallon. Gasoline and benzine are unchanged, but higher prices are certain in the near future. Files are a shade higher, the new and general discount being 70 per cent. A change in discounts on carbon drills is looked for shortly.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Col. N. Golejewski, Military Attaché, Room 904 Flat Iron Building, New York City.

Metal Market

The situation in the metal market is unchanged and prices with the exception of tin are the same as last week. The lead situation is the most interesting feature and the market is strong. The "Trust" price is still below outside quotations, but the reason for this is not very clear. The tin market in New York is easier, due to large arrivals of metal, while copper is dull and unchanged. Spelter is weaker, following a decline in London, but quotations are unchanged. The antimony situation is unchanged and quotations are nominal. There is nothing of particular interest to note regarding aluminum and the market is stationary. Prices of solder are unchanged, but firm.

Copper—The market is firm and dull, with quotations nominal. The position of copper continues to be strong as indications point to a heavy consumption for many months. The present dullness, however, may be accounted for by the fact that there is now enough copper for sale to take care of any demand that is likely to develop for the next two months at least. Local quotations are nominal and unchanged at 30½c per pound.

Tin—Although the market is easier in New York, due to large arrivals of tin recently, a recovery may be looked for in the near future. The London market is strong, due to increased demand and supplies of spot metal are getting lower. The consumption of tin has increased considerably and will likely continue to do so for months to come. Tin has declined 1c and quotations are nominal at 55c per pound.

Spelter—The market is quiet and steady following the recent activity. The demand for spelter is light, consumers in the meantime staying out of the market awaiting developments. Local quotations are unchanged at 22c per pound.

Lead—The situation is unchanged, but at the same time it is unprecedented. It is difficult to determine the actual level of prices, as the "Trust" price is nominal and it is not selling at that figure, but will sell in April at the average of its own quotations for that month. The demand for lead is heavy and the market has an upward tendency. Local quotations are unchanged at 10½c per pound.

Antimony—The antimony situation remains unchanged. The scarcity of spot metal is acute and the market very firm. Quotations are nominal at 48c per pound.

Aluminum—The market is quiet and quotations nominal at 68c per pound.

Solders—Prices are firm and an advance may be looked for as both tin and lead are likely to go higher. Guaranteed is quoted at 31½c and strictly at 29c per pound.

Winnipeg, Man., March 25.—Local shops which had orders for shells, appear to have had their contracts renewed. Labor conditions are becoming somewhat acute in Western Canada, it being not an uncommon thing to find several engineering firms advertising in city papers for machinists. The shortage is due to a large number of work-

men having enlisted during the past two or three months. Wages being paid are comparatively high. Speaking generally, the machinery business is fairly active, although in some lines there is considerable difficulty in getting deliveries. A large number of enquiries are coming in for lathes, but in most cases dealers are unable to meet them.

Following the phenomenal advances which have taken place in the prices of steel and iron, there is meantime somewhat of a lull. The opinion is expressed, that it will not be very long before prices move on the up grade again. Jobbers who handle threshers' supplies have been buying heavily.

DEVELOPING OUR EXPORT TRADE

THE Federal Government with an eye to the extension of trade in all countries where Germany was intrenched before the war, has made arrangements to send experts not only to several of the South American countries, but to Europe as well. Andrew J. Dawes, director of the Merchants Bank of Canada, Montreal, while discussing this energetic move on the part of the Ottawa Government, said that already a number of men had been selected by the Department of Trade and Commerce as capable of working up Canadian trade with foreign countries, and he particularly mentioned Russia, Chile, Argentine, and perhaps Brazil.

Mr. Dawes said he knew the man who would go to Russia, and that he was proficient in the Russian tongue and would be quite at home in any part of the Czar's dominions. The old Russia had passed away, and, after the war, that country would open its doors to Britishers and Canadians quite as freely as to any others, consequently Mr. Dawes expects that the efforts of the Canadian Government will be amply rewarded for the steps now being taken to get the trade that once belonged to the common enemy.

He also designated the proposition to send expert trade commissioners to South America as a step in the right direction, adding that, while the man going to Brazil would have to speak Portuguese, the commissioners to the Argentine and Chilian republics would have to be familiar with Spanish.

Germany's success in South America was not because their goods were better than the products from other countries, but because the Teuton manufacturers endeavored in every way possible to meet the wishes of their customers, both in the quality of the goods sold and in the size of the packages, which, Mr. Dawes declared, meant much to South American buyers.

GERMAN PERIL AFTER WAR

"GREAT BRITAIN and her Allies will face a new peril after the present conflict in an industrial war for which Germany has long been preparing by the creation of a new and formidable class of highly skilled workmen." This statement was made by Viscount Haldane, the former Secretary of State for War, in an address at the University of London.

"I want to sound a warning of what is in store for us," he continued. "I am more afraid of an engine for conquest in peace time, which the Germans were busy preparing before the war, than I am of the 42-centimetre guns. This engine is educational. The most modern form of continuation school is extending itself over a large part of Germany, and it is planned to extend it over the whole empire. It is a work school for imparting trade skill and general knowledge, rather than a mere book school, and it behoves us to be prepared for the shock of this competition which is coming after the war. Germany is training the youth of the land in special skilled trades, to outdistance competitors throughout the world."

BRITAIN INCREASES PROHIBITED GOODS

A LENGTHY extension of the list of articles, the importation of which is prohibited, which was farcast by Walter Runciman, President of the Board of Trade, was announced in London, on March 24 by the Board of Trade. The Board gave notice that a proclamation would be issued shortly prohibiting, after March 30, the importation of the following goods:

Baskets and basket ware, except of bamboo; cement, chinaware and pottery, not including cloisonne wares; cotton yarn, cotton piece goods and cotton manufactures of all kinds, except hosiery and lace; cutlery; fatty acids; furniture, manufactured joinery and other wood manufactures, except lacquered ware, hard ware and hollow ware; oilcloth, soap, toys, games and playing cards, wood and timber of beech, birch, elm and oak; woolen and worsted manufactures of all kinds except yarns.

The importation of these prohibited goods will be allowed only under a licence, but the Board of Trade states such licenses will generally be granted only for goods on the way to the United Kingdom or goods actually purchased when the notice is issued.

WAR OFFICE GIVES CANADA PREFERENCE

THE recent criticisms in the Canadian Parliament of the High Commissioner's office in London have caused considerable surprise amongst the Canadian community in London. As regards war orders all representatives of Canadian industries agree that Sir George Perley and his secretary, Mr. Griffith, have done their utmost. Harrison Watson, the Trade Commissioner, has frequently emphasized the fact that the limitations of orders was on account of Canadian unpreparedness for the rush of work. The British Government departments have given the preference to Canadian over American firms. On matters touching expert knowledge there are numerous Canadian railways, banking and financial corporations which are at the disposal of the High Commissioner's office if required. The office staff, which was charged with lacking Canadians, has the advantage of including several who have been attached there for many years, are thoroughly familiar with Canadian affairs.

EXPORT OF NICKEL FROM CANADA

THE Government has passed an order-in-Council prohibiting the export of nickel to any but British countries. The order applies to nickel, nickel ore and nickel matte. Since the outbreak of war, nickel has been exported from Canada to the United States under license. The Order-in-Council has been passed, upon the recommendation of the Minister of Customs, Hon. Dr. J. D. Reid, following a lengthy investigation of the question of nickel exportation.

On the outbreak of war, the desirability and importance of preventing Germany and her Allies from securing nickel originating in Canada was given consideration by the Government and steps were taken to prevent Canadian nickel from finding its way to enemy destinations. An arrangement was made with the International Nickel Co., of New Jersey, which controls the bulk of the Ontario nickel production, whereby the exports of refined nickel from the company's plant in the United States were checked by an official of the Canadian Government. This arrangement was made with the knowledge and approval of the Imperial Government. Since then the statement has been made in Parliament by the Solicitor-General, Hon. Arthur Meighen, that not a pound of Canadian nickel has gone to Germany since the war began.

Will Establish Plant

Some months ago the Government entered into correspondence with the International Nickel Co., with a view to having a plant erected in Canada for the treatment of Canadian nickel ores, and the company agreed to establish a refinery sufficient to take care of all the

Empire's needs in regard to nickel. It was intimated that this plant would be established somewhere in Nova Scotia. Whether or not any further steps have been taken by the company toward the establishment of this plant is not stated, but under the prohibitory order, now passed, this arrangement for the treatment of Canadian nickel ore in Canada will have to be carried out if other facilities for the manufacture of nickel within the Empire are not provided.

The nickel deposits of the Sudbury district of Ontario furnish about eighty-five per cent. of the world's nickel supply. Nickel is recovered also from the silver-cobalt ores of the Cobalt district. The largest producer of nickel outside of Canada is the French colony of New Caledonia. The Order-in-Council which has been passed by the Government prohibits the export of a number of other products besides nickel, except to British countries. The list includes asbestos, which is used largely in furnace construction; sugar, refined and refined; candy, wood ashes, pepper. The prohibition is "to destinations other than the United Kingdom or British Possessions.'

WAR LOSSES IN METALS.

THE losses of all the metals have been multiplied many times by the great war, says the Engineering Magazine. The British high explosive or shrapnel shell goes to the field with a brass head which is unscrewed, thrown away, and the time or percussion fuse screwed in. This fuse is also usually of brass, and the shell has a copper ring to take the grooves of the rifling. The shell is fired, and the copper and brass are lost. If the shell is shrapnel, the lead-antimony bullets are lost also. The French shoot a rifle bullet which is pure copper, the other nations, one containing considerable lead and usually antimony, sometimes with a nickel-steel or supronickel jacket. Every detonating cap used results in the volatization of a little mercury. Early in the war it was estimated that 112,000 metric tons of copper were being consumed yearly by each side, much of which is unrecoverable. The figure is probably low. The trench-furrowed fields of Europe will probably make rich picking for a while for the old-metal man, but most of this spent wealth will almost inevitably be lost.

STEEL CO. OF CANADA MEETING

THE directors of the Steel Company of Canada, at a meeting held at Toronto last week, wiped the slate clean of dividend arrears on the cumulative preferred stock by declaring a 3½ per cent. dividend on back dividend account, in addition to the regular 1¾ per cent. dividend for the quarter. When the two dividends, totalling 5¼ per cent. and calling for a disbursement of $341,555, are paid on May 1 next, full amends will have been made to shareholders for the temporary loss sustained through the deferring of payments from the fall of 1914 to the fall of 1915.

Considering that the company resumed regular quarterly payment only six months ago, the arrears have been paid off in exceptionally short order. After a lapse of a year, with 7 per cent. owing to shareholders, the company put the stock back on a dividend basis last September with a 1¾ per cent. declaration for the third quarter of 1915. In December, with the final quarterly delaration for the year, it was decided to pay 3½ per cent. on back account, or a dividend of 5¼ per cent. in all. That was paid on February 1st. With a like dividend to be disbursed on May 1, shareholders will have received a total of 10½ per cent. in amount three months.

Company in Strong Position

The rapid paying off of the accumulated dividends furnishes convincing proof of the strong cash position which the company has built up in the past year or so as well as of general prosperity in the steel industry. The February and May disbursements call for the large sum of $682,110 and it may be presumed at once that the directors would not have committed themselves to such a quick clearing of the slate if it were likely to jeopardize the working capital position. For instance, it would have been far from unsatisfactory to shareholders had the board decided to back one back dividend with each quarterly dividend through the current year. The ability and willingness of the company to discharge its obligations to shareholders without further delay is inferentially impressive of a position of unusual strength.

Domestic Business Developing

Following the meeting, C. S. Wilcox, the president, issued a brief statement to the effect that the most encouraging feature of the company's business at the present time was the extremely healthy growth of domestic orders. The future of the company, he said, did not depend, to the extent generally believed, upon its war orders.

EXPORTS OF GASOLINE FROM THE UNITED STATES

REPRESENTATIVES of the oil industry in New York claim that the high price of gasoline is due in large part to the enormous foreign demand and heavy export movement. Retailers and consumers dispute this claim, asserting that conditions do not justify it. Following are presented some facts concerning the export situation:

The total exports of crude oil and refined oil in 1915, according to the Government figures, amounted to $2,329,575,-617 gallons, an increase of almost 100,-000,000 gallons over the total for 1914. The amount exported in 1914 was 2,-240,033,652 gallons; in 1913, 2,186,565,-721 gallons. In two years, then, there has been an increase of approximately 200,000,000 gallons, slightly less than 10 per cent.

Exports of crude oil, gasoline illuminating oil and residuum were considerably less last year than in 1913. Exports of gas oil and fuel oil and naphthas, except gasoline, were approximately twice as large as in 1913. Exports of lubricating and heavy paraffine oil showed some increase. The following table shows the exports during a three-year period:

	1913.	1914.	1915.
Crude oil, gals....	194,569	124,735	158,263
Gas and fuel oil ..	358,008	634,298	799,646
Gasoline	117,728	162,669	112,560
Illuminating oil...	1,119,441	1,010,449	836,998
Lubricating oil...	207,639	191,647	239,719
Naphthas, except gasoline	70,315	47,028	169,770
Residuum	67,868	69,209	12,616
Total refined	1,941,996	2,115,298	2,171,312

Exports to the allied countries were generally heavier than in 1913, particularly of lubricating oil. Germany, which was a considerable factor even in 1914, did not receive any oil from the United States.

DOMINION TRADE WILL MARK RECORD.

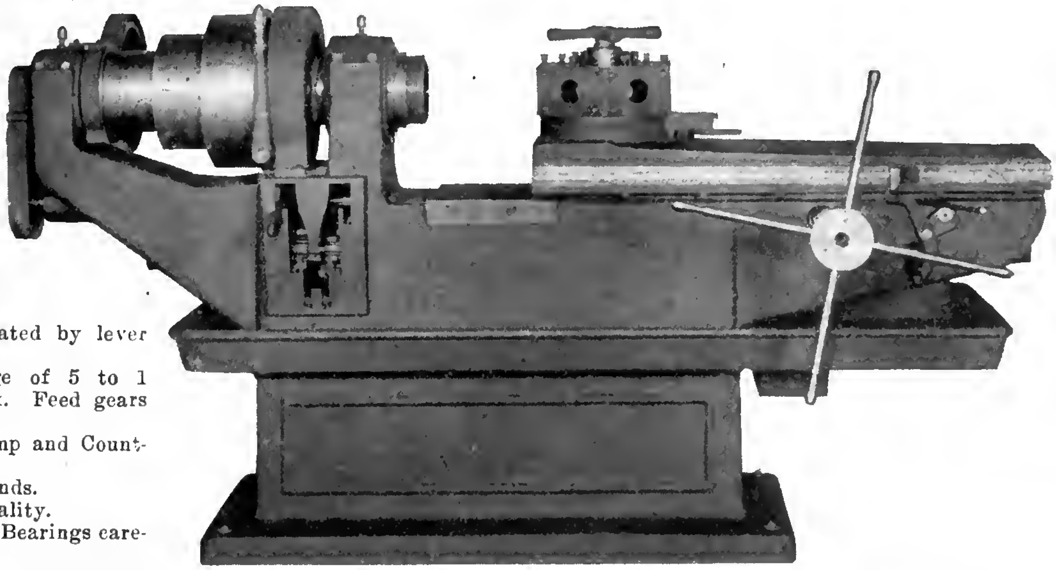
THE total trade of Canada for the fiscal year ending March 31 next will in all probability reach the record figures of one and a half billion dollars, according to the monthly trade statement issued by Hon. Dr. Reid, Minister of Customs, on March 16. The figures for the eleven months ended February last were $1,300,000,000, and March should easily bring the total up to the one and a half billion mark. The principal feature of the statement is the large increase in the volume of exports over the corresponding period of 1915, the domestic exports for the eleven months of the present fiscal year being $653,196,-000, compared wth $364,299,000 for the same months of 1915. The exports of February last were double those of February, 1915, being $58,000,000, against $28,000,000.

The export of manufactured articles again heads the list with $28,600,000, as against $8,900,000 for February, 1915. The exports of agricultural products for last February nearly doubled the export for February, 1915, being $13,000,000, against $7,000,000. There is an all round increase in other exports, with animals and their produce $5,500,000; lumber, etc., $2,500,000; minerals, $5,-

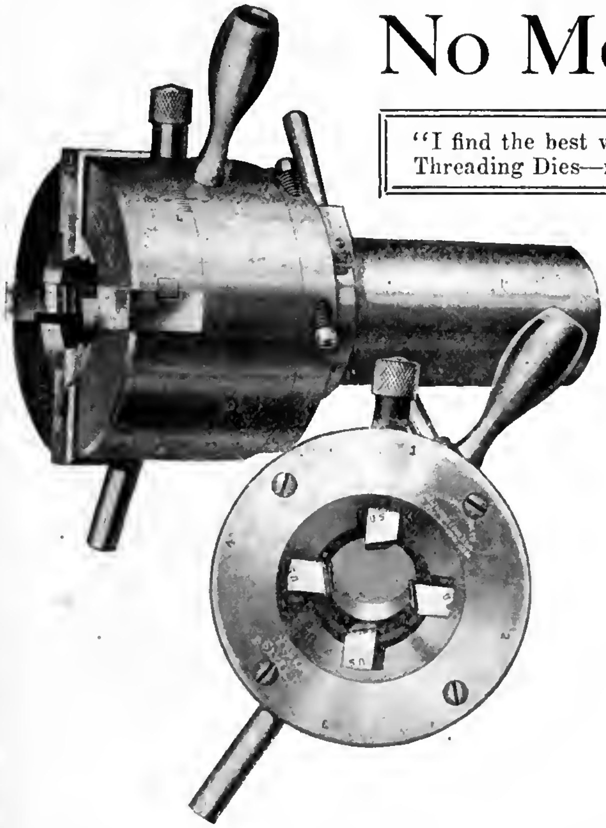
GREENSBORO TURRET LATHE

For Boring and Recessing Base of 4.5 and 6" Shells

Spindle is made of Carbon Steel, 8" diam. in front bearing and bored 6¼" diam. 8" deep, so part of shell is held within bearing to prevent overhang.
Spindle runs in heavy bronze bearings.
Head has friction back gear, 5½" belt.
Turret is bored for 3" Bars, has power feed with automatic stop.
Quick-change feeds operated by lever under head.
Turnstile has a leverage of 5 to 1 though gearing into rack. Feed gears made of steel.
Equipment: Oil Pan, Pump and Countershaft.
Weight: About 6,000 pounds.
Workmanship of Best Quality.
All Spindles ground. All Bearings carefully scraped.



THE A. R. WILLIAMS MACHINERY CO., LIMITED
TORONTO CANADA



No More Broken Threads

"I find the best way to get a full even thread is to use Geometric Threading Dies—no more broken threads."

The above comment was made by a Shop Foreman. His opinion is the opinion of every mechanic who has used Geometric Die Heads.

Geometric Self-opening and Adjustable Screw-cutting Die Heads are made with shanks to fit the turret of all makes of hand and automatic Screw Machines.

When you are ready, take up your threading proposition with us.

Get acquainted through our literature. Tell us the class of threading you have to do, and we will send booklet describing the proper tool to produce it.

000,000, and fisheries, $1,800,000.

For the eleven months Canada exported as follows:—Agriculture, $231,000,000; animals, etc., $94,255,000; fish, $20,000,000; minerals, $58,000,000; lumber, $48,000,000; manufactures, $195,000,000. All these items show remarkable increases, particularly that of manufactured goods, the export for the under this head being $70,000,000. Imports for February last amounted to $51,654,000, of which $22,550,000 were free goods. For the eleven months last the imports were $445,748,000, of which $191,000,000 were free goods. Corresponding period of 1915 showed total imports of $414,959,000, of which $158,000,000 were free goods.

The Chapman Valve Mfg. Co., of Indian Orchard, Mass., have opened an office at 727 Traders Bank Bldg., Toronto with A. R. Roberts as representative.

Trade Gossip

Vancouver, B.C.—The Board of Trade have elected Nicol Thompson president and B. W. Greer vice-president.

Calgary, Alta.—The cement plant at Exshaw near here will recommence manufacturing in a few weeks.

The Canadian Ice Co.,Toronto, Ont., has been awarded a contract for installing a refrigeration plant by Smallman and Ingram of London, Ont.

Chatham, Ont.—The following officers have been elected to the Board of Trade: President, A. E. Taylor; vice-president, W. F. Cassidy; secretary, D. P. MacLachlan; treasurer, Howard McKendy.

Cobourg, Ont.—At the annual meeting of the Board of Trade the following officers were elected: President, W. J. Maher; first vice-president, W. W. Hooey; second vice-president, A. L. Jex; secretary-treasurer, T. S. Chatterton.

The Canadian Sarco Engineering Co., manufacturers of traps and other steam specialties, have opened an office at 727 Traders Bank Bldg., Toronto, A. R. Roberts, is president and general manager of the company.

Copper Bounty Proposed.—The Hon. Lorne Campbell, Minister of Mines for B. C. Legislature announced in the House that the Dominion Government was considering the proposal of a copper bounty for British Columbia, which would place the province in control of the copper and zinc output of Canada.

St. Catharines, Ont.—The City Council decided to strike a rate of 40 cents per 1,000 for the first 5,000 feet of natural gas, which the city has engaged to purchase from the Relief Gas Co. The rate after the first 5,000 feet is 35 cents. The rate charged by the company for the first 1,000 feet is 70 cents, with meter rental.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

St. George, Que.—G. P. Gonthier will build a foundry here, at an approximate cost of $4,000.

Shawinigan Falls, Que.—The Canada Carbide Co. will make extensions to its plant to double the capacity.

Ingersoll, Ont.—Preparations are under way for the installation of the new purification works at the plant of The Ingersol Gas Co.

New Toronto.—The Brown Copper & Brass Rolling Mills, Ltd., are having a brass rod and shape mill erected here which will cost about $125,000.

Toronto, Ont. — The National Equipment Co., manufacturer of gasoline engines, pumps, etc., is erecting a tank shop, in which new machinery will be installed.

Chatham, Ont.—The American Well Works Co. of Aurora, Ill., is putting its plant here in order, and installing machinery for the manufacture of pumping machinery, etc. F. J. Lukins is manager.

Grandmere, Que. — The Laurentide Co. will build an addition to its plant to double its capacity. Machinery will be installed in the addition and 15,000 h.p. additional will be required to operate the plant.

Sudbury, Ont. — The Sudbury Construction & Machine Co., is building additions to its plant, including a cupola house 30 x 40 ft., in which a new furnace will be installed and an addition 30 x 40 ft., is being made to the brass foundry.

Montreal, Que. — The Canada Iron Foundry Co., which completed a reorganization last fall, is contemplating building an addition to its plant at Three Rivers, Que. Either an entirely new plant will be erected, or a large addition added.

Saulte Ste. Marie, Ont.—The Great Lakes Power Co., a newly organized corporation composed of United States' capitalists have purchased the power plant and streeet railway belonging to the Algoma Steel Corporation. Plans drawn up by the Great Lakes Co. provide for improvement of the local power plant to the extent of nearly $3,000,000. The Great Lakes Co is reputed to have already been bonded to the extent of $2,200,000. It is planned to develop 30,000 h. p. in the completed plant, nearly all of which has already been contracted for by the Algoma Steel Corporation.

Electrical

Sarnia, Ont.—The electric light plant here will probably be taken over by the Hydro Commission

Wellesley, Ont.—An electric lighting and power system will be installed in this village at a cost of $7,500.

Toronto, Ont.—The Toronto Hydro-Electric System will build an extension to the Duncan Street sub-station.

Brantford, Ont.—The wireing of the City fire alarm system will cost heavily. Copper has been tendered for at $33.15 per 100 pounds, and there are 16 miles to be done. Two new alarms will be placed at a cost of $100 each.

Sarnia, Ont —The Hydro Commission of Sarnia is planning a lighting system for the waterfront including the frontage of the G.T.R. and Northern Navigation Co. One thousand Candle-power ornamental lights are planned for the business section, and a large number of nitrogen filled lamps for side streets. Railway and boat companies will also be asked to improve their river frontage.

Municipal

Calgary, Alta.—The incinerator which was recently destroyed by fire will be rebuilt.

Elmira, Ont.—Extensions will be made to the waterworks system. A. M. Bauman is the contractor.

Hamilton, Ont.—The City Council will purchase a motor fire truck from the National Steel Car Co., of this city. The price is $5,300.

Toronto, Ont.—The current estimates of the property department include $14,000 for an addition to the civic abattoir, including two boilers.

Barrie, Ont.—The Water and Light Commission contemplate installing a new pumping plant to replace the present one which is out of date. A new stand pipe will also have to be considered.

Calgary, Alta. — The Entertainment Committee of the City Council have recommended that the City appropriate $1,000 to assist the Board of Trade in a scheme to advertise the Calgary district. Mr. Campbell is secretary of the Board of Trade.

Kingston, Ont.—The City is now appealing to the Hydro-Electric Commission for power, since the latter has bought out the Seymour Electric Co., with which the local Utilities Commission was about to make a contract for power from the Trent River.

Toronto, Ont.—The estimates for the Fire Department include the purchase of an automobile for Chief Smith, two motor combination hose and chemical wagons, a motor hook and ladder truck, 7,000 feet of $2\frac{1}{2}$ in. fire hose, a fire tug and fire alarm telegraph.

General Industrial

St. Catherines, Ont. — Fire recently damaged the Cuthbert Pattern Works to the extent of $3,000.

Regina, Sask.—The Prairie Biscuit & Confectionery Co. are planning to erect a $50,000 factory here.

Toronto, Ont. — The York Knitting Mills are making an extension to their factory on Queen St., West.

Hamilton, Ont. — The Mercury Mills Ltd., propose erecting a knitting factory here at an approximate cost of $250,000.

Toronto, Ont. — The York Township Council wil extend the water distribution system. Cast iron pipe and hydrants will be required.

Carleton Place, Ont.—New machinery is being instaled at the Hawthorn Mills which will increase the capacity of the plant.

Linlsay, Ont. — The chemical Co. is awarding contracts for the supply of materials for the new factory. Mr. Hodgson is manager.

Lindsay, Ont. — Another industry, the Waddell Preserving Co., will shortly purchase or erect a factory here for manufacture of their products. The directors are: Fred W. Ryerson, president; W. E. Long, vice-president; J. A.

Man'f'rs of "Barnes-made" Products
Springs, Screw Machine Products, Cold Rolled Steel and Wire

SINGLE PURPOSE LATHES

Open belt drive and back geared.

Early Deliveries

Plain, efficient manufacturing machines. Their cutting capacity will surprise you.

Himoff Machine Co., Inc.
132 Mott Street, New York

If any advertisement interests you, tear it out now and place with letters to be answered.

Waddell, managing director and secretary; T. E. Ryerson, treasurer.

Port Arthur, Ont.—The Saskatchewan Co-operative Elevator Co., of Regina, Sask., will build an elevator here with a capacity of two and a half million bushels. C. D. Howe, chief engineer of the Board of Grain Commissioners will design the elevator which will be constructed of reinforced concrete and will be equipped with modern drying and cleaning apparatus. C. A. Dunning of Regina is manager of the company.

Tenders

Halifax, N.S.—Tenders will be received up to Wednesday, April 5, for 5,000 feet of cast iron pipe. Specifications, etc., may be obtained at the office of F. W. W. Doane, City Engineer.

Quebec, Que.—Tenders for freight shed and grain galleries, will be received at the Quebec Harbour Commissioners' Office, Pointe-a-Carey Wharf, Quebec, up to April 15 next. Plans and specifications of the contemplated work may be seen at the Harbour Engineer's Office, Pointe-a-Carey Wharf St. George Boswell, Chief Engineer.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control City Hall, up to Tuesday, April 11, for the supply and delivery of: Electrically operated driving gear for operating 36-inch gate valves, at main pumping station, John Street. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders for underground work, addressed to the chairman Toronto Electric Commissioners, will be received until Tuesday, April 4. Details of work to be performed, consisting of laying of cable ducts, building man-holed and transformer vaults. Specifications and form of tender may be obtained at the Engineering and Purchasing Department, 15 Wilton Avenue.

Vancouver, B.C.—The British Columbian Fisheries, Ltd., will sell their entire plant and equipment, including buildings, machinery, tools, refrigerating plant, sawmill and machinery, fertilizer plant and equipment, power plant equipment, steam trawlers and scows, etc. Tenders will be received up to April 15, and full particulars may be obtained from James Keppel Ball, Yorkshire Building, Vancouver, B.C.

Collingwood, Ont.—Tenders will be received by the Chairman of the Collingwood Water and Light Commission until Tuesday, April 11, for the following works—(1) Pumping machinery, comprising two motor-driven units, 1,000 Imperial gallons capacity each. (2) Pump well and connections. Plans and specifications may be seen at the office of the Chipman and Power Engineers, 204 Mail Building, Toronto, or at the office of the Water and Light Commission, Collingwood, Hugh A. Currie, chairman.

Ottawa, Ont.—Tenders will be received until Tuesday, April 4, for the purchase of the following scrap metals: Lot No. 1.—Mostly flat iron, approximate weight, 8,000 lbs.; Lot No. 2.—Conduit and gas pipe, approximate weight 800 lbs.; Lot No. 3.—Miscellaneous wrought and cast iron, approximate weight 20,000 lbs.; Lot No. 4.—Wrought iron pipe, approximate weight, 7,000 lbs.; Lot No. 5.—Gas pipe and conduit, approximate, 600 lbs.; Lot No. 6.—Galvanized iron pipe and wrought iron pipe, approximate weight, 1,600 lbs.; Lot No. 7.—Structural iron (straight), approx. weight, 12,550 lbs.; Lot No. 8.—Structural iron (twisted approx.), weight, 32,000 lbs.; Lot No. 9.—Rod iron, approximate weight, 1,000 lbs.; Lot No. 10.—Sheet copper, approximate weight, 23,800 lbs.; Lot No. 11.—Brass, approximate weight, 100 lbs. The above material can be examined any week day, between 10 a.m. and 4 p.m., on the Parliament Grounds, to the rear of the Parliament Buildings, by applying to the Public Works Officer-in-charge of the Buildings, Room 21, House of Commons, West side. R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Railways—Bridges

Hamilton, Ont.—In order to overcome the difficulty in securing a proper entrance to the city of Hamilton, a bridge 1,400 feet in length will be erected by the Toronto-Hamilton Highway Commission. The highway and the Hydro radial will both run over this bridge.

The Buffalo Fort Erie Ferry & Railroad Co., is seeking power to acquire and take over the assets and property formerly owned by the Buffalo & Fort Erie & Ferry Railway Co., now owned by Frank V. E. Bardol. The provisional directors are: Frank V. E. Bardol, Alex. Fasken and James Oscar Bucklay both of Toronto. The capital is $500,000, and the head office of the company is to be at Fort Erie, Ont. The company seeks authority to extend the line to Port Colborne through the southern portions of the townships of Bertie and Humberstone, and between the Buffalo and Goderich division of the G.T.R. It also proposes to extend the line from Fort Erie to Chippewa by way of Bridgeburg.

New Incorporations

The John Dickinson & Co., has been incorporated at Toronto, Ont., with a capital of $40,000 to carry on the business of paper manufacturers and wholesale stationers at Toronto, Reginald G. Allder of Toronto is Attorney.

The National Mines Ltd., has been incorporated at Toronto, Ont. with a capital of $2,000,000 to acquire and develop mineral lands and deposits at Cobalt, Ont. Incorporators, John Albert Rowland, Dunbar Tyler and David H. Stewart all of Toronto.

The Waddell Preserving Co., has been incorporated at Toronto with capital of $40,000 to manufacture all kinds of jams, and canned goods, etc., at Brantford, Ont. Incorporators, James Harley, Edmund Sweet and A. M. Harley all of Brantford, Ont.

The Hodgson Brothers Chemical Co., has been incorporated at Toronto, Ont. with a capital of $200,000 to manufacture and distil, methylate, chemicals and spirits, etc. at Lindsay, Ont. Incorporators, Thomas Hodgson and Jas. Irwin Harrt of Lindsay, Ont.

The Consumers Heating Co., has been incorporated at Toronto with a capital of $100,000 to construct and operate works for the production and distribution of steam and hot water. The head office is at Toronto, and the Incorporators, Dixie Cox Cotton, George Alexander Tee and Harry A. Colson all of Toronto.

Contracts Awarded

Montreal, Que.—The contract for the erection of an addition to Darling Bros., factory, has been awarded to A. F. Byers & Co. Estimated cost, $19,000.

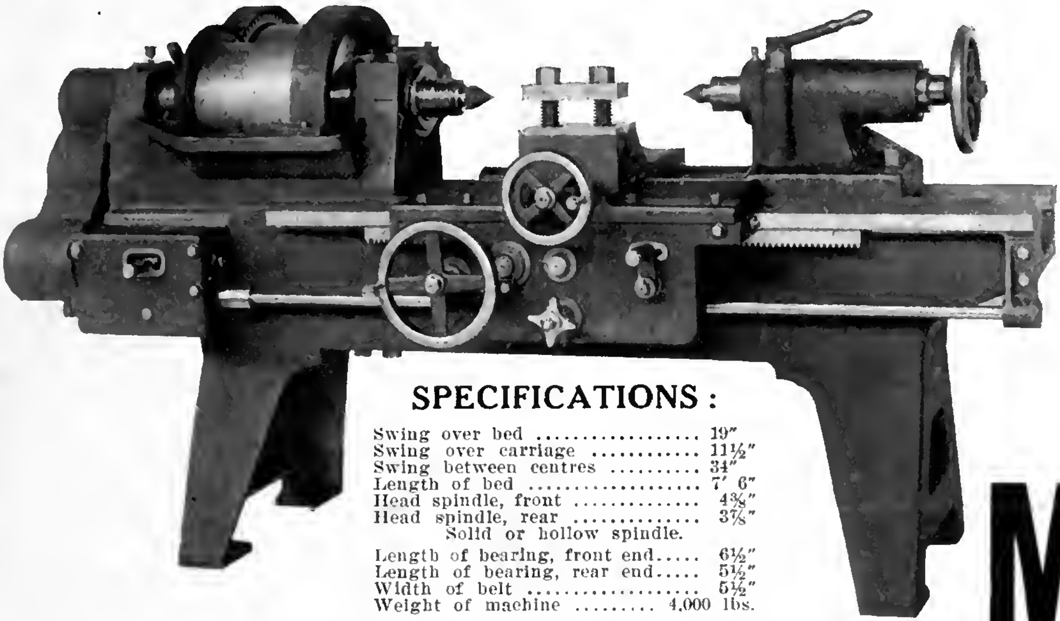
The William Hamilton Co., of Peterborough, Ont., have been awarded a contract for hydraulic equipment by the Portneuf Hydro Electric Co., of St. Albans, Que., for the new power plant.

Toronto, Ont.—The contract for the erection of a radial brick chimney at the Don incinerator has been awarded by the Board of Control to the Canadian Custodis Chimney Co., Toronto, at $10,070.

Hamilton, Ont.—The City Council have awarded the following contracts for supplies for the year:—Brass work, the Tallman Brass Co., cast iron pipe Gartshore-Thompson Pipe & Foundry

The "Duplex" Heavy Duty Engine Lathe

Can also be supplied with 4 or 6 side Turret.



SPECIFICATIONS:

Swing over bed	19"
Swing over carriage	11½"
Swing between centres	34"
Length of bed	7' 6"
Head spindle, front	4⅜"
Head spindle, rear	3⅞"
Solid or hollow spindle.	
Length of bearing, front end	6½"
Length of bearing, rear end	5½"
Width of belt	5½"
Weight of machine	4,000 lbs.

10 READY FOR PROMPT DELIVERY

Guaranteed to rough turn six-inch steels.
As good as any and better than many.

Building Notes

Vancouver, B.C.—The Ford Motor Co., of Canada has purchased a site and will erect a four-story building of brick and concrete, 110 x 115 feet. W. G. Patrick is local manager.

Winnipeg, Man. — Arrangements for the building of the rear portion of the new city hall are now being seriously considered by the Board of Control. The work is expected to cost in the neighborhood of $200,000 which covered by a loan at 5½ per cent., would cost the city $11,000 per annum, but would bring all the departments under one roof.

Marine

Port Arthur, Ont. — The ice-breakers are making good headway, and it is expected they will cut a channel to the open water of Lake Superior by the end of the week.

Victoria, B.C.—To replace the tender Quadra, sunk in collision with the Charmer at the entrance to Nanaimo Harbor, the Dominion Government has decided to charter a suitable vessel to work in conjunction with the tenders Estevan and Leeboro. The steamer will be in buoy, beacon, and lighthouse work along the British Columbia coastline.

Refrigeration

Lethbridge, Alta.—A deal has practically been closed for a site near North Lethbridge on which P. Burns & Co., the packers will build an abattoir to meet the needs of their growing business in Southern Alberta.

Wood-Working

Wyoming, Ont. — William Travis is considering the construction of a planing mill, at an estimated cost of $4,000.

Personal

Robert Davies proprietor of the Don Valley Brick Works, Toronto, Ont, died on March 22, aged 67.

William R. Waghorne, manager of the Hydro-Electric System at Wallaceburg, Ont., died on March 23.

G. L. Pearsons has been appointed secretary and general manager of the Goderich Elevator & Transit Co., Goderich, Ont.

J. McCormick, for the past nine years connected with the sales department of Mussens Limited, Montreal, has resigned, having accepted a similar position in the machine tool department of the Canadian Fairbanks-Morse Co., of Montreal.

W. J. Curle, of Toronto, has been appointed general manager of the C., W. and L. E. Railway, to succeed the late William Norris. Mr. Curle was formerly connected with the C. P. R. and C. N. R., the latter road having control of the C., W. and L. E. R.

Mark Workman, President of the Dominion Steel Corporation has left Montreal on a trip of inspection to the Company's coal and steel properties in the East. He will be away for some time, his intention being to make a thorough survey of the properties, particularly the recent extensions.

Trade Gossip

Cobalt Ore Shipments.—Following is the official list of Cobalt ore shipments, in pounds, for the week ending March 24; Peterson Lake, 68,878; McKinley, 83,731; Penn-Canadian 97,883; Buffalo, 61,895; Dominion, 172,000; Townsite City 82,091; Cobalt Lake, 87,000; Nipissing, 129,780; Tamiskaming, 61,000; Beaver, 65,019.

Armstrong Whitworth of Canada Ltd., Montreal, Que., have opened a sales office in the Dominion Bank Bldg., Toronto, in charge of J. L. Hynes who is acting as representative for Toronto and district. This has been done with a view of giving individual attention to the business and extending the company's connection.

The Turbine Equipment Co., Toronto, Ont., have sold to the town of Mount Forest, Ont., a De Laval centrifugal pump having a capacity of one million Imperial gallons per day and to be operated by a 50 h.p. Canadian Westinghouse motor. This equipment will be installed in the waterworks pumping station.

Controlled Factories in Britain.—The Minister of Munitions announces that he has made an Order under Section 4 of the Munitions of War Act, 1915, declaring 218 additional establishments to be controlled under the Act, as from March 6, 1916. A total of 3,052 establishments have now been declared as controlled under the Act, from the date of the first Order, July 12, 1915, to March 3, 1916, inclusive.

The Canadian Car & Foundry Co., of Montreal, have secured a large order for freight cars from the French Government, the value running into several million collars. The order follows one of

two thousand freight cars for the French Government, closed last December. The new contract, with equipment orders now on hand amounting to about $5,000,000, promises continued activity in the company's car shops for some months to come, altogether apart from the shell business. The Russian shell order, it is stated, is working out satisfactorily, shipments going forward at regular intervals and without further technical or financial difficulties.

GERMANY'S TRADE AFTER THE WAR

THE situation of the German iron and steel industry at the present time is reported to be exceptionally firm and enjoyed a production exceeding 1,000,000 tons of pig iron and steel per month, after an output of 11,790,000 tons in 1915, says the "Engineer." There seems no reason for doubting that a considerable quantity of iron and steel is now being used, apart from the continued demands of the army authorities, in the production of many articles which were formerly made of copper and other metals.

In the confident expectation that the production of pig iron will be maintained after the war, and possibly brought up to the level of 19,310,000 tons which was reached in 1913, the general manager of one well-known steel company recently stated that from the experience gained in the autumn of the first year of war enormous stocks of ammunition were necessary, so that the manufacture of munitions would continue after the war, especially as Turkey and Bulgaria were dependent upon Germany for their supplies. In addition to these requirements the Germans declare that extensive deliveries which have long been desired by some neutral countries will then have to be executed, and that Europe after the war will be comparable with a great arsenal, in which each country will accumulate large stocks of munitions in accordance with the lessons taught by the war, "it probably depending entirely upon Germany as to how far the country is willing to extend her deliveries to foreign States.

Raw Materials Supply

The question of the supply of raw materials after the war is naturally intimately connected with that of the manufacturing industries from the standpoint of the resumption of the latter and their development. Apart from large purchases of copper, cotton, agricultural machinery and tractors which are reported from the United States to have been made in that country by German agents and to have been already in part loaded on the ships interned in the ports, the War Committee of German industry, on

the one hand, and industrial and official circles in Austria on the other, are at present occupied with the problem.

At a recent meeting of the War Committee held in Berlin, when 200 manufacturers from all parts of the country and representatives of the Ministries for Foreign and Home Affairs and of War were present, it was unanimously resolved to deal with the matter by the formation of sub-committees representing the varied interests of trade and industry, shipping and the large banks, and in close association with the Government Departments. Beyond this statement the proceedings were of a confidential character. On the other hand, less reticence has so far been observed in Austria, as the question was fully discussed at a recent gathering of the Industrial Club in Vienna, when speeches were delivered by the president of the Central Association of Austrian Manufacturers, the secretary of the well-known Austrian Commercial Museum, and representatives of the Ministry of Commerce.

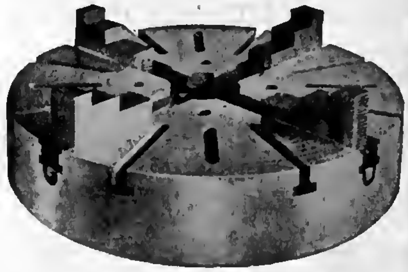
The chief idea, which is also that which prevails in Germany, was that syndicates should be formed with the assistance of the banks for the purchase of raw materials for distribution among consumers so as to minimise the difficulties and dangers which would arise in procuring them, and thus preventing excessive upheaval in the changing over from war work to peace pursuits. The aid of the Government was desired to some extent, but doubts were entertained as to the wisdom of the State exercising great influence in the matter.

HUGE TONNAGE LOSSES THROUGH WAR

THE European war has taken from the seas more than 200 merchant vessels of nearly 4,000,000 tonnage, according to figures published on March 20, by the Department of Commerce, Washington, Germany, with 600 vessels, sunk captured or detained, heads the list of losers.

Two hundred and twenty-five of the 500 British vessels lost were sunk by submarines. Through mines the Allies lost 167 ships, Austria lost 80, and Turkey 124. The total of neutral losses is put at 736, but most of these were released after being reported captured. Ninety-two neutral vessels have been submarined and 94 sunk by mines.

Great Britain has lost, according to the sources of information available 485 ships, with a total tonnage of 1,506,415. The Allied countries of France, Italy and Russia have lost altogether 167 ships with a tonnage of 282,187. The number of German ships lost by cap-



ture or sinking is 601, with a total tonnage of 1,276,500.

Eighty Austrian merchant vessels have been lost, making a total tonnage of 267,664. There has been 124 Turkish ships lost, but no adequate estimate of the tonnage has been secured. Neutral ships have been sunk to the number of 736, with a tonnage of 441,472.

AUSTRALIA'S METAL INDUSTRY

ADDRESSING a meeting in Queensland recently, Mr. Hughes, the Australian Prime Minister, referred to the mining industry. He said that when war broke out, for all practical purposes, the entire base metal trade of Australia was in the hands of a great German combine, whose tentacles extended all over the civilised world. This great German organization manipulated the market to suit itself. In Australia the position was that the war at one blow had closed all old channels along which base metals ordinarily found their way to the market. This trade represented at least £15,000,000, yearly, excluding the value of gold and silver, in base metals.

The policy of the Government, which was to encourage the industries of Australia, had resulted in largely extending the facilities for treating lead, zinc, and copper ores within Australia. All copper goods required in Australia would shortly be manufactured there. When the war ceased, Australian industrial activities would be greatly increased. It would be to Britain and her Allies only that the metal industry of Australia would look for markets. In every direction generally the Government would vigorously push that policy. Australian goods would take the place of German. A national laboratory was to be established, and the services of the best scientific men available would be secured.

Catalogues

Buffing and Polishing Wheels.—Bulletin 200 deals with various types of buffing and polishing wheels made by the Munning-Loeb Co., Matteawan, N.J. The selection of raw materials for buffing wheels and their manufacture is dealt with fully. The principal feature of the various types and grades of wheel are described in detail, while price lists, dimensions and weights are also included. The different types of wheel are illustrated.

Screw-Driving Machines.—The Reynolds Pattern & Machine Co., Moline, Ill., have issued a bulletin dealing with the Reynolds automatic screw-driving machine for wood or machine screws. A general description is given covering the principal features of these

machines and method of operation. This is followed by a number of illustrations, showing the various types, accompanied by a brief description of each, stating the class of work for which they are adapted. The bulletin includes a list of users.

Steam and Air Motors.—The Dake Engine Co., Grand Haven, Mich., have issued an attractive catalogue describing an interesting line of steam and air motors, hoisting engines, stearing gears, capstans, windlasses, etc. The power-driven machinery dealt with in the catalogue is driven by the Dake square piston engine, which is fully described. Each type of machine is illustrated and featured, and the principal dimensions given for each size. The Dake marine line is dealt with in a separate section of the catalogue, and includes various types of power-driven deck machinery.

Book Review

The Briitish Dominions Year Book, 1916, published by the British Dominions General Insurance Co., 1 Royal Exchange Avenue, London, England. This useful and interesting publication is edited by Edward Salmon, F.R.C.I., and James Worsfold, F.C.I.S., and is a successor to "War Facts and Figures," issued by the company last year. The book contains primarily a long series of interesting articles written by well known authorities, dealing with various phases of the war and other subjects of national interest. Among the articles may be mentioned: "The First Year of the War," by E. Charles Vivian; "The Imperial Navy," by the late Fred T. Jane; "The Cost of the War," by Edgar Crammond; "The Rally of the Dominions," by Edward Salmon; "A Business-like Empire," by Sir Leo Chiozza Money; "How the British Army is Organized for War." by Henry Neville; and other articles, all of special interest at this time. The book also contains a series of shorter articles dealing with various subjects, such as a few facts concerning the countries of the world, including the British Empire, "Who's Who in the War," a list of V.C.'s awarded up to September 11, 1915, and other information and statistics, each of special interest. The book also contains four maps, several diagrams and colored plates, showing medal ribbons and badges of rank for the army and navy. There are 336 pages altogether, including a list of contents and index. It is perhaps the most interesting publication of its kind that has appeared since the war started, containing as it does a fund of useful information and views on many subjects pertaining to the war by reliable authorities.

Machines and Methods Used in Spectacleware Manufacture

Staff Article

The successful production of high-grade spectacleware at competitive prices is largely, if not wholly dependent on a wide knowledge of tool room practice, combined with inventive resourcefulness in the adaptation of manufacturing methods. It is interesting to note that Canadian manufacturers of spectacleware are not only able, as a result of these conditions, to meet competition from all quarters, but supply as well a considerable proportion of the world's requirements and these of a widely diversified description to suit all races of mankind.

MODERN spectacleware is a product which for its successful manufacture depends very largely on the resourcefulness and skill of the tool room staff. Occasional operations other than straight machine work enter into the work—cable winding, soldering, plating, etc.,—but about 95 per cent. of the shaping, sizing, and similar work is dependent on machine shop methods and devices for profitable production.

The material used for the goods is a yellow composition metal, gold cased, and obtainable in the form of sheets, rods, wire, etc. The conventional design of spectacle frame is shown in Fig. 1., the lenses being encircled by metal eye-pieces, and thin side wires or temples with thick ball-ended curves being hinged at the end piece as shown.

Eighty operations more or less, are required on a frame of the type illustrated. Many of these at first sight seem almost trivial, but the cumulative effect is observable as the work progresses, and when the finished product is inspected, the value of each step becomes still more apparent.

Component Parts

The work is divided into four distinct groups which are gradually assembled together at various stages, i.e., end-piece, eye-piece, bridge, and temple. The end-piece shown in Fig. 2, is formed from flat stock of a suitable section, gold-cased on both sides and stamped out in such a manner that the casing of gold is retained on the tapered edges shown. These end-pieces are really two pieces formed in one, the advantages of this method over the former method of separate stampings being evident to anyone experienced in press work.

VIEW OF STAMPING PRESSES AND BENCH MILLERS.

Views (a), (b), (c), (d), Fig. 2 show the principal stages in making and assembling the end piece. After being stamped (a), a groove is milled, the eye-piece held in position and the sides of the groove pinched so as to hold tightly in place while being soldered, the latter operation being accomplished by holding the work in the flame of a small bunsen burner and touching heated parts with hard wire solder to complete operation.

The milling of the groove and the pinching of the end piece are both done in the one machine see Fig. 3. It consists of a gear driven spindle carrying a small convex milling cutter about 1-16 in. thick, the spindle being mounted in a swing frame hinged on the shaft which carries the belt pulley at the back of the machine. The front part of the frame forms a handle which is gripped by the operator when bringing the cutter into action.

The end-piece is placed between two small jaws or dies which are inserted into a hole in the work table, being clamped tightly in place by a pedal underneath the bench. The frame is now swung down, causing the cutter to groove the end of the work so that the eye-piece can be assembled in place. The operator holds the wire ring, which forms the eye-piece, so that the joint in the ring is in the centre of the thickness of the end-piece, see (b) Fig. 2. Pressure on a pedal now causes the jaws on either side of the work to advance and pinch sides of the grooved end-piece so as to make it grip tightly on the ring after which it is finally secured by means of soldering.

Eye-Piece

The wire of which the eye-piece is formed is circular in section, and is close-wound on a coiling mandrel, the size of which is accurately determined so that the wire, when released, will

VIEW OF ASSEMBLING DEPARTMENT, SHOWING GAUGING, STRAIGHTENING, INSPECTION, ETC.

spring to a size just a shade smaller than the diameter of the slitting mandrel. This is necessary so that when slipped on to the slitting mandrel, the coil will be opened very slightly, with the result that after being slit, the ends of each ring will lie snugly together.

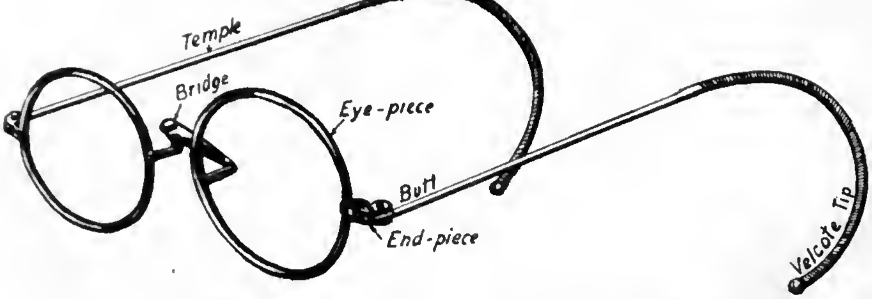

FIG. I. MODERN SPECTACLE FRAME WITH VELCOTE TEMPLES.

If the ends of the rings should hang apart, and not be held together by the operator when assembling with the end piece, the finished eye-piece would be too big for its lens.

Before coiling, the wire is passed through rolls which form a groove on one side of it, and when being coiled, the wire is passed between tension blocks of hardwood, which also guide it so that the groove is accurately located on the inside of the ring. When transferred to the slitting mandrel, the coils are clamped between two plates, as shown in Fig. 4. Two grooves are provided on the mandrel—one on top for clearance for the slitting saw, and the other exactly opposite for marking a point on the inside of the frame by means of the strip shown in upper part of the illustration. This strip has a small knife-edge projection at one end, which is undercut so that it can be sprung together when entering the slot, and as it is drawn through, it marks each eye-piece in passing.

End-Piece

The soldered end-piece is now placed in a die and struck so as to set it truly radial from the centre of the eye-piece, after which it is sawn through the centre thus splitting the ring and enabling access to be had to the face of each piece for the purpose of indenting a small D-shaped depression, and piercing two holes the size of which varies according to whether it is the upper or lower half (c). The outer end of the end-piece is next reduced in thickness by an amount equal to half the thickness of the end of the temple which is later assembled at this point. The cut is taken at an angle, as shown at (d) but as will be observed it does not entirely remove the D-shaped depression in (c). The space left by this depression provides clearance for the end of the temple, Fig. 5. In order to form points (x) and (y) which act as limiting stops for the swing of the temple, the cut is carried straight across as shown. This cut is made with a horizontal end mill, the work being held by hand with the end piece supported in a suitably shaped depression in a die block.

The machine used for this milling operation is of a type adaptable to various operations and is illustrated in photo Fig. 3. It consists of a swinging frame carrying the spindle which is gear-driven from the pulley shaft, the swing frame being hinged on the bearings of the shaft.

Piercing and Tapping

The end pieces are now ready to have the screw and dowel holes made. Fig. 6 shows the two halves of the completed end piece with dowel pin in lower half. The fillister head screw is shown, along with a plate used during assembly operations. Each half of the end piece has the holes punched in a separate fixture, the supporting die having an accurately fitting recess in which the end-piece rests. The end-piece rests on its flat or outer side while the eye-piece is sprung sideways by hand to clear the punch. Tapping the screw hole is now done in a special machine of simple design. Fig. 7 shows the principle on which it operates. A solid tap is held in the spindle chuck while the end-piece to be tapped is held by hand in a slot cut in the side of the tailstock spindle. This allows the spindle to be used with the hand feed for engaging the work with the tap, the work being kept square by the back face of slot. A hole in the centre of the spindle is made to allow clearance space for the tap. The main spindle is carried in two bushings supported in the headstock, and forming part of the belt pulleys, each of which is coned on one side to engage with a double-sided cone on the spindle. When the work is pressed against the tap, the main spindle slides back till it engages with the rear cone which thereupon revolves the tap in the hole, the work being followed up lightly with the hand feed. When the tap is through far enough, the hand feed is pulled back, causing the work to disengage the spindle from the rear cone and pull it into the front one. The cross belt on this cone pulley reverses the tap and runs the work off.

Counterboring and Dowelling

In counterboring the hole the work is held flat on a block. A small spring plunger pin projects above the surface for the purpose of locating the hole under the drill spindle, see Fig. 8. The vertical tube at the side of the spindle is fastened to the table and acts as a guide for a finger clamp which is pressed down by the spindle and, being spring supported, allows the counterbore to travel to the desired depth. The counterbore has a short pilot which as it descends forces the locating pin down into the block.

After reaming the dowel pin holes, the dowel pin is inserted. A slight gash or dent is made on the portion of it which is fastened in the end-piece, and after being forced into the hole, the metal is compressed around it by a small revolving tubular tool similar to rotary riveting. The dowel pin is therefore keyed into place and cannot be removed without considerable risk of damaging the end piece. The small plate shown in Fig. 6 is of steel and the same thickness as the end of the temple. It is now put on the dowel pin, the screw tightened up, and an accurate blow delivered to the end-piece in a die, which strikes up both sides flat, with end of pins flush, etc.

The ends of the eye-piece may not be accurately matched so far as the groove is concerned, so a small round edge cutter is used to clean out any surplus solder and continue the groove past the joint in good shape.

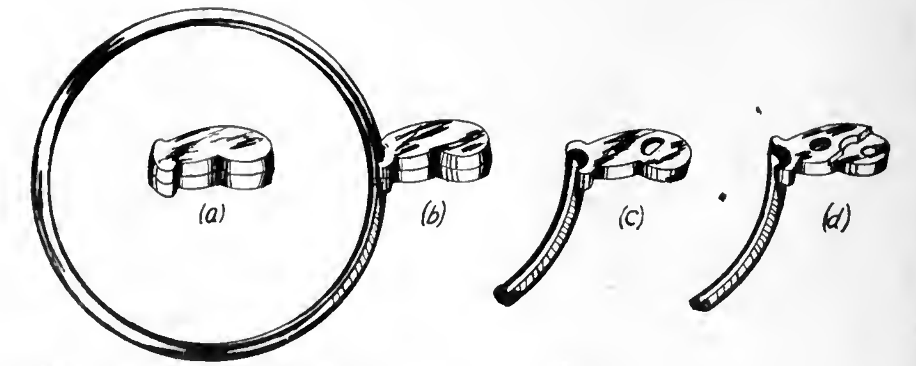

FIG. 2. END-PIECE IN DIFFERENT STAGES OF COMPLETION.

Bridge

The bridge is now assembled with the

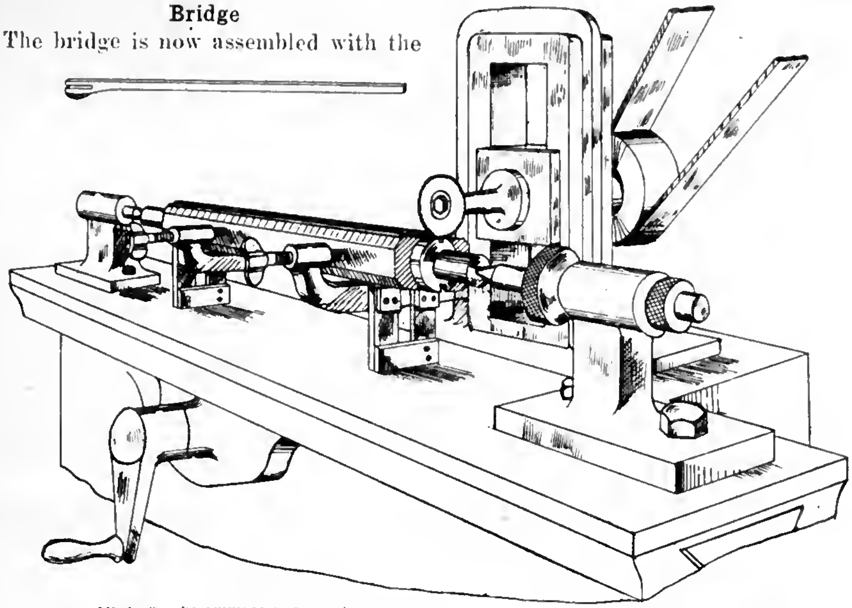

FIG. 3. SLITTING COILS OF WIRE TO FORM EYE-PIECES.

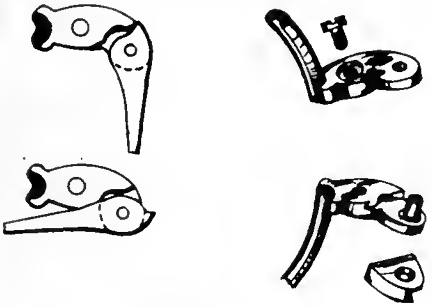
eye-pieces, being soldered in position as shown in Fig. 9. The upper portion as this illustration shows the various stages



FIGS. 5 AND 6.

in the manufacture of the bridge. Reference was made to a mark which was made on the inside of each eye-piece before it was cut off on the coiling arbor. That mark indicates the spot on the outside of which the bridge is attached. After cleaning, the soldered joint is bumped in the press to flatten out the joint, after which the eye-pieces are stretched on an expanding block which sets them to an oval shape of the desired size.

The bridge must now be bent to shape, this operation being done in a specially built machine which allows of any desired proportions being imparted to the bridge. A photograph of this machine is reproduced in Fig. 10, while a sketch showing the three positions of work is given in Fig. 11. At (a) is shown the work as it is when placed in the revolving jaws. When handle A, Fig. 10, is swung round to the right, the jaws are caused to revolve through a quarter turn, bending the work as at (b) Fig. 11. Handle B, Fig. 10, is now pressed forward causing the round nosed forming plate to bend the bridge into the familiar shape as shown at C, Fig. 11. Handle C, Fig. 10, is drawn forward and sets the bridge to the desired angle by means of the small pin shown, the travel being adjustable for various angles of bridge.

After being brushed and cleaned, the temples are fitted to the frame, following which a buffing and final cleaning completes the work.

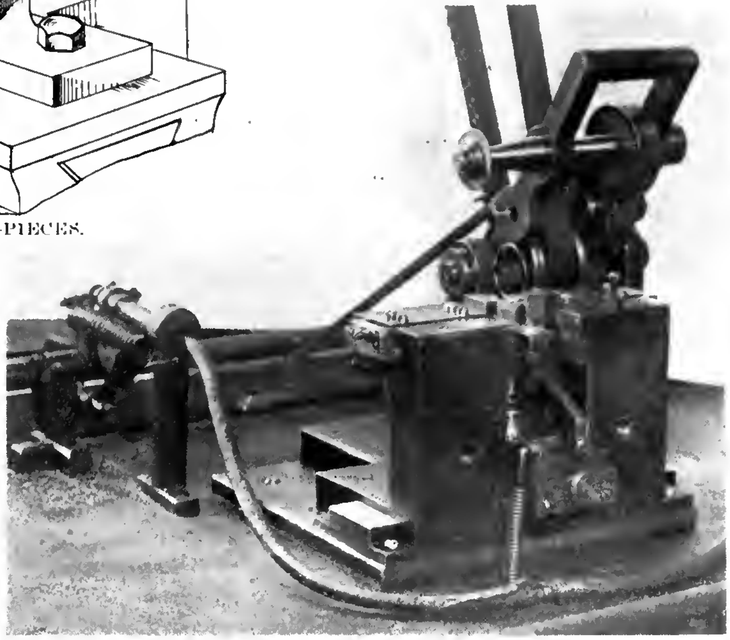


FIG. 4. SWING TYPE BENCH MILLING MACHINE WITH SLIDING JAWS FOR CLAMPING END-PIECE.

Making Temples

The temples or side wires as they are perhaps more frequently spoken of, may be of several types such as a solid wire, cable wire, or velcote—a combination of

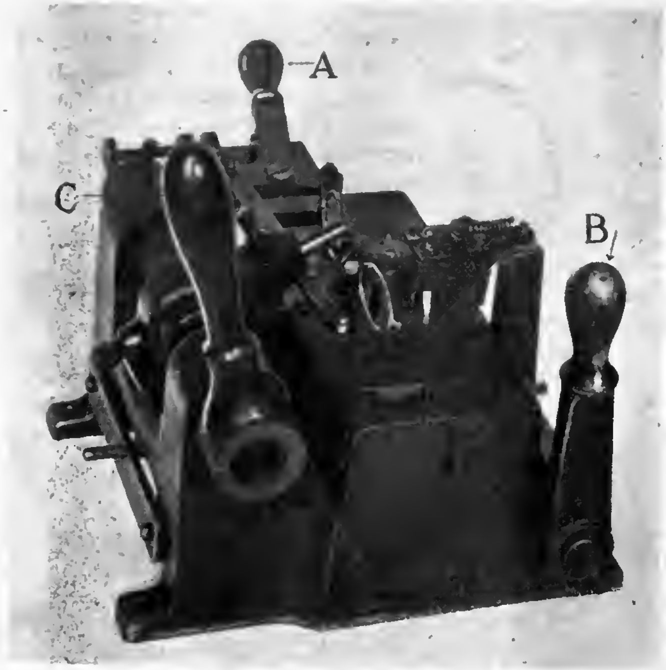

FIG. 10. MACHINE FOR BENDING BRIDGES, SHOWING FINISHED ARTICLE IN JAWS.

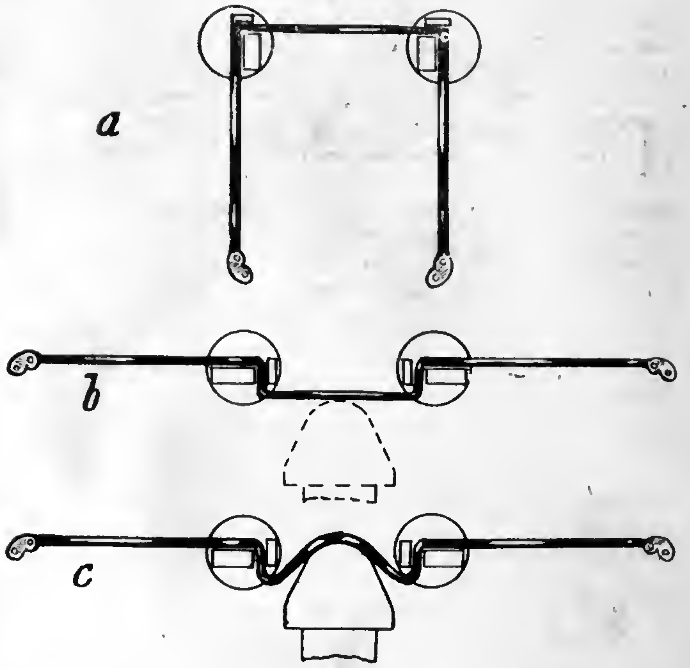

FIG. 11. ILLUSTRATING ACTION OF BRIDGE BENDING MACHINE.

wire and cable. The latter type is the one shown in the illustration of the complete frame. The construction is explained in Fig. 12. The velcote is built

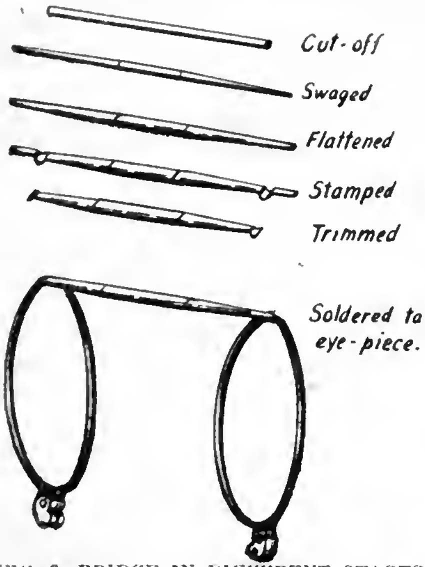

FIG. 9. BRIDGE IN DIFFERENT STAGES OF COMPLETION.

up of nine wires, four of these being wound round a single wire to form the core. An outer layer of gold-cased wire is next laid on, four wires wide, after which pieces of the velcote are cut to length, pointed to fit the countersunk end of the butt and soldered. Two swagings and annealings are now performed to hammer down the soldered joint and drawn out the butt to a thin wire. A third swaging without annealing, imparts a finished surface and shape and leaves the metal hard and strong. The velcote is swaged also, the effect being to pack the coils of wire closely together, and impart a smooth finish.

The butt is then stamped flat, pierced, trimmed, and finally flattened to the thickness of the wire.

The ball end is now put on, this being formed from a flat blank, cupped, assembled on velcote and stamped in hemispherical dies. After being assembled with the frame, the velcotes are bent to shape by being twisted round a small spindle, the coils being made right and left-handed. In order to make the velcotes retain their curved shape a burnishing tool is worked across the inside surface of the curve, the resulting surface hardness having the effect of causing the velcote to resume its curved-shaped even if stretched out straight.

The final operations are all performed by hand and consist of gauging various dimensions, straightening, centering, sizing, etc.

The methods and devices illustrated are in use at the Toronto factory of the Consolidated Optical Co., to whose superintendent W. Beck, we are indebted for assistance and information in preparing this article.

National Machine Tool Builders' Association.—The executive committee of the National Machine Tool Builders' Association having decided that, in view of the great stress of business, the association give up its usual spring convention with its regular program, there will be held in its place a conference of members who may attend the National Metal Trades Convention in New York, April 27 and 28. This conference will be on the day following, namely, Saturday, April 29, at Hotel Astor. It will be absolutely informal without any fixed program, but open only to members that they may discuss freely the many perplexing problems they are facing.

REPAIRING A HOISTING ENGINE DRUM

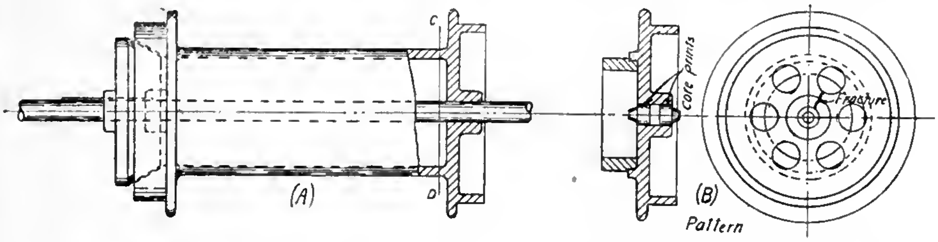
By H. C. F.

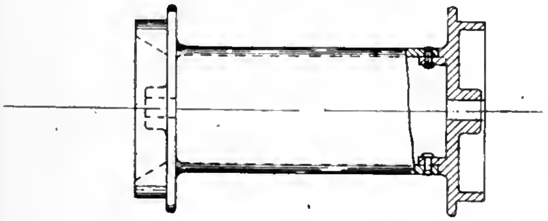
THE class of work with which repair shops have to contend is of such a nature that ingenious methods must be devised in order that a particular job may be finished as quickly as possible, with at the same time attainment of the best possible results, an example of how a small shop successfully dealt with a seemingly hard job is indicated as follows:

During the unloading of a hoisting engine at a railroad construction camp, it was found that one of the hubs of the drum had become somewhat seriously cracked. To shrink a band on the hub would have proved impracticable since the drum had to be free to revolve on the shaft, and such a procedure would have the tendency to bind it tight, so it was finally sent to the machine shop with orders to put it in first-class working condition in the shortest space of time possible.

The job was first placed in a large lathe, being chucked by the sound hub, and supported by a large pipe centre in the tailstock. A cutting-off tool was then inserted and the entire end cut off close to the flange as shown by the line CD, upper sketch A. The end thus cut off was made into a pattern by providing it with a heaving ring and core prints as shown in sketch B.

When this was cast, the brake flange was machined to the correct size, and the ring turned down to make a snug fit for the end of the drum. The latter had been previously set up on the lathe carriage, and the end roughly bored, so as to insure a good fit for the end piece when driven on. A series of countersunk rivet holes was next drilled around the diameter of the drum, and the end piece riveted with ⅝ in. boiler rivets, as shown by lower figure. These were hammered in hot, the head being held from the inside with a suitable holder on.





HOISTING ENGINE DRUM REPAIR.

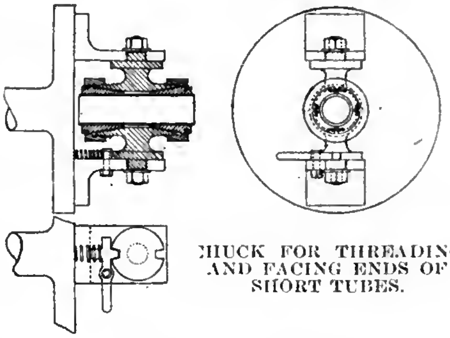
To complete the job, it was only necessary to bore the end piece to fit the shaft. This was accomplished by again setting the work up on the lathe carriage and boring by means of a long boring bar. In other words, the lathe was made to take the place of a horizontal boring machine. Considerable care was necessary, in lining up the work in order to ensure that both holes would be in direct line, as otherwise an unusual amount of trouble would be met with in placing the shaft in position.

Upon completion of this operation, the drum and shaft were assembled and sent back to the camp. The time required to complete the job was about a day and a half, and as for the job being satisfactory—well, the engine ran continuously for nearly eight months, and when laid up for winter, the drum was still in first-class condition.

CHUCK FOR THREADING AND FACING ENDS OF SHORT TUBES

By Billy Dixon

THIS chuck is secured to two angle plates bolted to the lathe face plate. The holes in the two angle plates should be bored together, and the spigots of the chuck made a nice neat fit with no shake. The tube is inserted and gripped by the collets at each end. When the tube is extracted the collet sections are prevented from falling by the four small springs. After one end of the tube has been bored, faced and threaded, the nuts securing the chuck to the angle plates are loosened, the catch is released, and the 1.60 chuck swung round for machining of the second end; thus ensuring the two ends being true with each other and the faces parallel.



CHUCK FOR THREADING AND FACING ENDS OF SHORT TUBES.

GAUGES IN MODERN MANUFACTURING PRACTICE—I.

By F. H. Mayoh.

THE magnitude of the problems involved in interchangeable manufacture has increased to an extent which most mechanics recognize, none more so than tool designers upon whom devolve the necessity of providing a successful system of gauging suitable for every combination of tools met with in modern practice.

To get an idea of the numerous types of gauges in use, one may select some of them from a list of manufacturers' standard types, such as plug, ring, snap, transfer, disc, depth, thread, etc., and then add the large number of special gear, length and form gauges to numerous set blocks that are

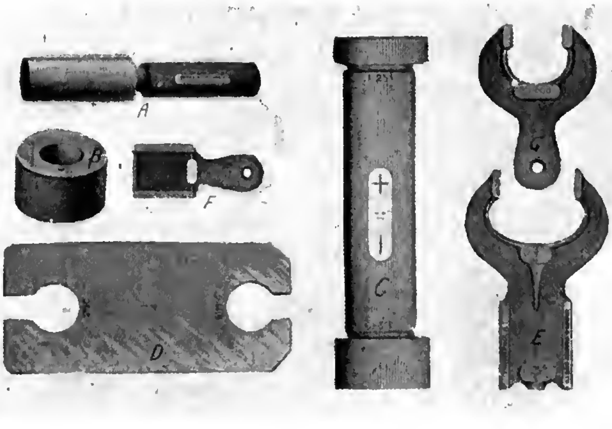


FIG. 1. (a)—PLUG GAUGE; (b)—RING GAUGE; (c)—PLUG LIMIT GAUGE; (d)—INTERNAL LIMIT GAUGE; (e)—DOUBLE-END CALIPER GAUGE; (f)—INTERNAL CALIPER GAUGE; (g)—EXTERNAL CALIPER GAUGE.

in use for locating cutters, etc., in place, and we begin to understand that gauges are more than an after consideration.

Standard Gauges

For completeness, it has been deemed best to illustrate in groups a number of standard gauges, and referring to Fig. 1, we have a plug gauge A and a ring gauge B which are for standard internal and external measurements; a plug limit gauge C and an external limit gauge D, which go on at one end and fail to go on at the other end and which are often marked with readily distinguished signs to help in preventing errors. Standard caliper gauges E of the double-end type are also shown in Fig. 1, and these are also made in the single-end type F and G. Referring to Fig. 2, standard types of depth gauges are shown, one of which, A, is provided with a scale. B is for use with various lengths of wire, and is of the spring type with a spiral spring in the barrel, which forces the blade against the bottom of a hole. A vernier depth gauge is illustrated at C and a micrometer depth gauge at D, the reading of these tools being taken in the usual manner, as provided for micrometers and verniers.

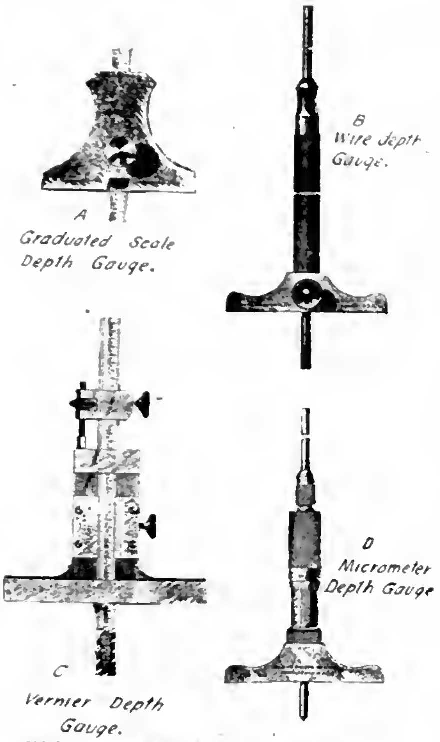

FIG. 2. VARIOUS TYPES OF DEPTH GAUGES.

A feeler gauge A, a thread gauge B, a centre gauge C, and a wire gauge D are shown in Fig. 3, while a surface gauge A, a drill gauge B, and a test indicator C, Fig. 4, serve to illustrate the general run of these tools. Besides these, there are sheet metal gauges, end measuring rods, reference discs, which are used for testing gauges and micrometers of various styles, inside, outside, thread and lengths, verniers, height gauges, bevel protractors, and numerous others, which one meets with in machine shop practice.

THE MAKING OF BETTER MECHANICS

By H. C. F.

ONE frequently hears the question asked as to which mechanic receives the better training—the one who learns his trade in the small, repair shop, or the one who began, by looking for the "left hand monkey wrench" in a large specialised manufacturing concern. The fact is evident that the class of work for which these respective shops are adapted is of a widely diversified nature, and methods of obtaining results as practised in one shop would be almost if not quite unknown in the other.

The majority of mechanics are inclined to give the smaller shop due credit for the class of mechanics it has turned out. Its work is by no means specialized and as a result its mechanics are not specialists on any one particular class of work but are expert on many.

Small Shop Conditions

The apprentice in a small shop is not started off by working for six months on a drill press, the next six months on a shaper, and so on, as is the usual procedure in a large shop, but instead he gets such a start that, by the end of the first six months he is able to take care of a considerable range of the work. The class of work demands this. Furthermore the apprentice is left more or less to his own ability. He learns to a great extent by experience and experience is at all times the best teacher. The foreman cannot be constantly watching the apprentice for he is nearly always busy on some other work, probably an "out job" so the result is that the boy "finds out" for himself, and information gained in such a manner is not easily forgotten.

Variety of Work

Then there is the class of work which the small shop man comes in touch with. To say, that he never knows what his next job will be is stating a real fact of the case as a result of which he has to be proficient enough to handle every job as it comes,—and handle it in the right way. One of the most important features of his work is the necessity for a sufficient knowledge of prime movers that will enable him to handle engine repairs quickly and efficiently. A knowledge of the steam engine, both stationary and portable, including threshing engines and tractors, is one of the essential requirements. He must be in a position to make repairs under adverse conditions and without the advantage of having the shops right at hand. It is then that the inventive qualities of the men are brought to bear upon the work.

A thorough understanding of a boiler is also necessary, more especially on the portable or traction engine boilers. The men in charge of these boilers are more or less inexperienced or careless in their work and burned crown sheets, leaky tubes, and stay bolts are frequent occurrences.

Repairs a Specialty

Patching a burned or cracked crown-sheet requires a certain amount of skill and a larger amount of perseverance. The use of oxy-acetylene welding is remedying conditions to a certain extent, its use being specially adapted to this class of work, but such an outfit is not at all times to be found, so the mechanic must rely on his quality of perseverance. He must possess it to win out.

A knowledge of electricity is also a necessity in order that the mechanic will be in a position to handle repairs which mighe be found necessary, in a power plant or sub-station. Then too, as a direct connection with electrical experience a knowledge of water power machinery, i.e. water wheels and turbines, is also essential and the rudiments of these are learned chiefly through practical experience.

Other Branches Necessary

Furthermore, the mechanic in the small shop is not necessarily a mere machine hand. He, as a rule, has other trades thrown in, each of course, bearing, more or less on the machine trade. He acquires a certain understanding of pattern making. He may not be an expert pattern-maker but nevertheless he becomes sufficiently acquainted with woodworking tools so that he is enabled to get out a more or less complex pattern and in a comparatively short space of time. His ability as a pattern maker does not alone make him a more adapt mechanic but he also becomes acquainted with a rudimentary foundry knowledge. Core-making and moulding with a knowledge of melting are all included in the learning of the machinist trade.

Also there is the work included in the blacksmith shop which is even more loosely connected with the machine trade. He often becomes equally proficient in this trade as well as his own, but, however, the essential part of it to the machinist, is the fact that it enables him to forge and dress his own tools.

The machinist then who learns his trade in the small shop, acquires not only the mere ability of being able to "run" every class of machine tool, and a practical insight into other trades directly connected with his own but he also learns to exercise his inventive

SECTION OF SMALL SHELL HYDRAULIC PRESS SHOP IN NEW BRITISH PROJECTILE-MAKING FACTORY.

abilities coupled with the usual quality of perseverance.

Aspect of the Large Shop

To look at the other side of the question we find a somewhat different state of affairs. In the large shop the apprentice in the majority of cases is kept on one machine for a period covering six to ten months. The result is that he becomes careless. He gets into a rut. He has a certain amount of work to do, he must do it in a certain way—the way the fellow before him used to do. The foreman gives him the job, he gets the jig, the machine runs along in the same old way and the boy becomes as the machine. He gets into the old routine "pick up, chuck up, cut up, let up". He loses all interest in work—his chief thoughts are centered on the whistle and on pay day. He doesn't feel inclined to exercise his brain power to an extent that will enable the work he is doing to be accomplished in a more acceptable way and should he devise some other means of doing such, he is not inclined to voice his opinion to the foreman. He thinks the man higher-up will give him the laugh.

Expert Machine Runners

After he has finished his four or five years apprenticeship, what, really, has he learned? True he might be a specialist on cutting gears or running a boring mill and while being admittedly proficient in running a machine he is sadly deficient in possessing a real understanding of the business. Foundry work, pattern work or smithing is practically unknown to him. He never has learned how to dress his own tools—that is the toolsmith's job—the result is in many cases that they are forged just the opposite way to his requirements. However he has to take the chance of getting them done right. He can't do them himself for the simple reason that he doesn't know the difference between a "fuller" or a "hardy."

Limited Opportunities

It is the same with regard to foundry work for he is at a loss to know even why the castings he is machining are full of blow-holes. It is true there are many—a great many energetic young machinists who will put themselves out to unearth the "why" and "wherefore" of these connecting trades, but the majority of their knowledge must be derived from books rather than from actual experience.

The so-called machinists then that are being turned out to-day by our large shops are really taking upon themselves a wrong name. They are merely operators or better still specialists. Their knowledge of the vast machine trade is limited to the one machine which they become proficient in operating. The real machinists are to-day very much in the minority. The shops that turn out men learned in every branch of the trade are gradually decreasing, and while they will not altogether disappear, the number of workers trained by them are an ever lessening proportion of our industrial army.

So long as specialization pays, and that would seem to be always, so long will the all-round mechanic of tried ability become scarcer, simply because the conditions necessary for his development no longer exist.

WHO'S WHO?

WILLIAM CASEY, recently appointed manager of the Canadian Locomotive Co., Kingston, Ont., was born in the latter city on October 13, 1887. He was educated at St. Mary's School and Regiopolis College, and entered the employ of the above company as office boy. Following this he served an apprenticeship in the machine shop, being transfered thereafter to the drawing office. In 1907 Mr. Casey was appointed machine shop foreman which position he held until 1912, when he returned to the office to take charge of piece work and estimating. In 1914 he was made assistant to the vice-president and general manager (A. W. Wheatley), and following the latter's resignation a few weeks ago, Mr. Casey received the appointment of manager of the Canadian Locomotive Company.

WILLIAM CASEY,
Manager, Canadian Locomotive Co., Kingston, Ont.

CONCERNING PREMONITIONS

By Woodworker

"I THOUGHT it would break, and it did." The above "wise saying" is heard much too often. It should not be heard at all, for whenever it is feared that something is going to snap, it should be thoroughly investigated, so that one's mind may again be at ease. If the design or construction is wrong, it should be made right. If your investigation proves that everything is O.K., very well, your premonition will vanish.

For some reason or other, an engineer friend of mine worried constantly about the belt that drove his exciter. He feared it would break any minute because it often slipped off the pulley on starting. He looked it over carefully every day. He kept the lacing in tip-top shape. He did everything, almost, except to investigate the matter. The belt was three times stronger than necessary and was amply safe. The exciter pulley was simply too small and the trouble was easily remedied. After the belt stopped slipping off, my friend had no more premonitions. However, had it broken before the investigation he doubtless would have said, "I thought it would break, and it did."

I can think of no case where a man who is entrusted to care for a plant could utter these words in a careless care-free manner, especially if the break is of a serious nature.

LABOR AND MACHINERY

THERE is nothing more pathetic in industrial history, says Engineering, than the conflict of labor with machinery. It has existed for a hundred years or more, during which time there has been a constant progress in comfort and well-being among the working classes. Yet even to-day the machine is looked upon with suspicion by the workman as something designed to filch his living from him. Curiously it is only the novel machine that is the subject of hostility.

If men were asked to do the old heavy work with chisel and file that obtained fifty years ago, they would indignantly refuse and ask why there were not planing machines and shapers to do the job. They do not object to a condition of affairs which has become established, and has lightened their toil, but an appliance that threatens even temporarily to produce a greater output fills them with apprehension.

All the efforts of the economists seem to have failed to spread clearer ideas on this subject; but until more accurate views prevail, it is difficult to see how the amelioration of the lives of the working classes is to be achieved. As a general proposition, a man gets about what he has earned in whatever class he is, and the way to get higher pay is to produce more.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

SHELL MAKING TOOLS

An important detail in the manufacture of shells is that of the chucks to be used for the various operations, and the following account of those made by J. & H. McLaren, Ltd., of Leeds, and taken from The Engineer, should be of more or less interest to Canadian shell manufacturers.

The chief features of these chucks are simplicity, rigidity and accuracy of finish. Fig. 1 represents two sectional views of one of the chucks, which comprises a central body A with flange B for securing to the adapter flange on the lathe spindle, an external nut C, and collet rings D, and three hardened steel jaws E, which fit in corresponding slots in the body. The jaws are prevented from falling out by means of screws and spiral spring buffers F, which are inserted through the body at right angles, the blind holes in the jaws into which they engage being shaped so as to allow of just sufficient movement of the jaws to enable the shell to clear. The nut C is provided with a right-hand

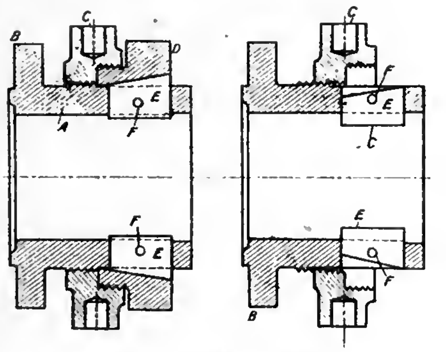

FIG. 1. COLLET CHUCK.

V thread for screwing on to the sleeve and a left-hand thread to receive the collet ring. The endwise movement of the conical collet on the taper jaws causes the latter to engage with the shell the movement being produced by the right and left-hand threads when the nut C is turned. The jaws are made of tool steel hardened and ground in place within limits of two thousandth of an inch.

Fig. 2 represents a sectional view of an expanding shell mandrel, in which B are the hardened steel jaws, held in position by spring buffers A, the jaws gripping the shell body by the endwise movement of the plug D, which is brought about by the screwed nut on the shaft G. The movement of the plug is limited by the washer C and ferrule E. For turning the copper bands on the shell bodies an adapter centre is provided, being shown in Fig. 3. Before

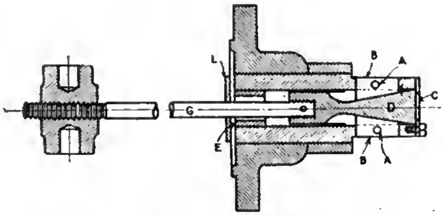

FIG. 2. EXPANDING MANDREL.

the shell reaches this stage it has been equipped with a base plug, and the original centre at that end has been removed. It is, therefore, necessary to adapt a centre to run quite true with the finished shell, and it is important that this device be firmly secured to the shell and run truly with it during the band-turning operation. It is also necessary to replace the ordinary centre in the loose headstock by the new centre shown.

The body of the adapter B is made a running fit on the centre, and is provided with a hardened piece C for the centre to bear against. This piece is screwed into the body by a left-hand thread. The body, is also coned to receive the spring collet D, which is bored out to take the end of the shell and turned outside to fit the cone in B. It is fitted with three studs E, which pass through the body, each having a small spring F, nut G and split pin.

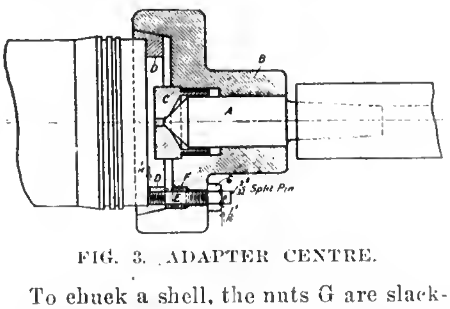

FIG. 3. ADAPTER CENTRE.

To chuck a shell, the nuts G are slacked back to the split pins, allowing the springs F to force the collet ring out of the cone and open to receive the shell base. When the latter has been inserted the loose headstock spindle is screwed up until the shell is held lightly in the centres. The lathe is then started, and, while running the further tightening up of the loose headstock spindle goes on until the shell finds its own centre. The lathe is then stopped and the loose spindle further tightened up until the shell is firmly gripped by the spring collet D. The three nuts G are then tightened up by finger and thumb only to retain the grip of the collet, and the loose headstock spindle is slacked off to a proper running fit.

Fig. 4 represents the equipment for forming the waves for the copper bands on shells on ordinary lathes. The shell on which the operation is to take place is held by an internal chuck at the nose end, while at the other end revolves in the lathe centre. A case-hardened roller path A is bolted to the chuck, and the hardened roller B is kept in contact with the path A by two powerful springs D D', which allow the lathe saddle to move freely endwise, while ensur-

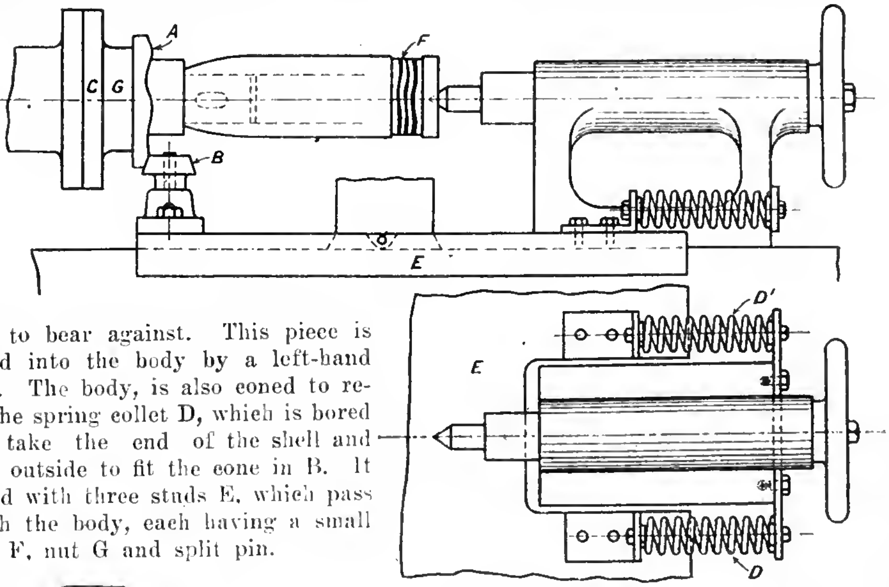

FIG. 4. COPPER BAND GROOVE WAVING ARRANGEMENT.

ing that the roller B follows the undulations of A when the tool is cutting.

For forming the internal radii of 4.5 in. high-explosive howitzer shells a special blending tool has been devised—views of which are given in Fig. 5 and 6. It is an extremely simple device, comprising a rigid bar or tool holder A B, in which is inserted the shaped cutter. This is securely held by means of pinching screws D D', E E'. The cutter

is set by resting a straight edge against the hardened and ground head A and the shoulder B. The end of the cutter next A is set to touch the straight edge, while the other end stands just

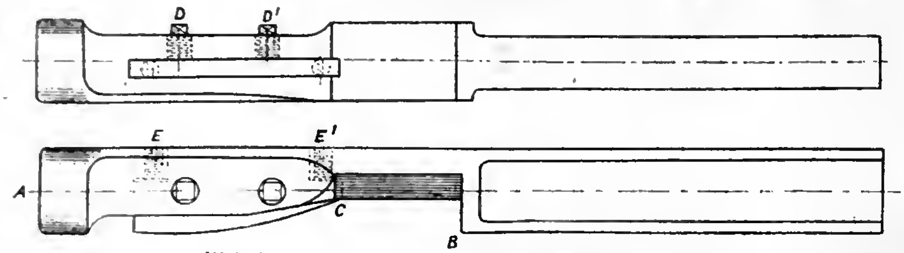

FIG. 5. BORING TOOL FOR INTERNAL RADII.

"proud" of the neck C. In setting the tool in the lathe it is essential that the head A and shoulder B should pass freely through the hole in the nose of the shell, giving a clearance all round.

After adjustment, the tool is inserted into the shell until the shoulder B just clears the outside of the nose. Then with the cross traverse the tool is moved sideways until the hardened head A just comes in contact with the shell wall. The tool is then traversed outwards and the material is cut away until the shell is sufficiently blended. To ensure absolute uniformity in blending, a gauge is necessary between the shoulder B and the nose of the shell.

In many works difficulty has been met with in the production of suitable dies to bottle the heavy thick-walled high-explosive shell. Fig. 7 represents the usual type of bottling dies, the bottom part being of steel and the top half, which closes in the heated nose of the shell, of close-grained cast iron. On shells of medium thickness, the dies

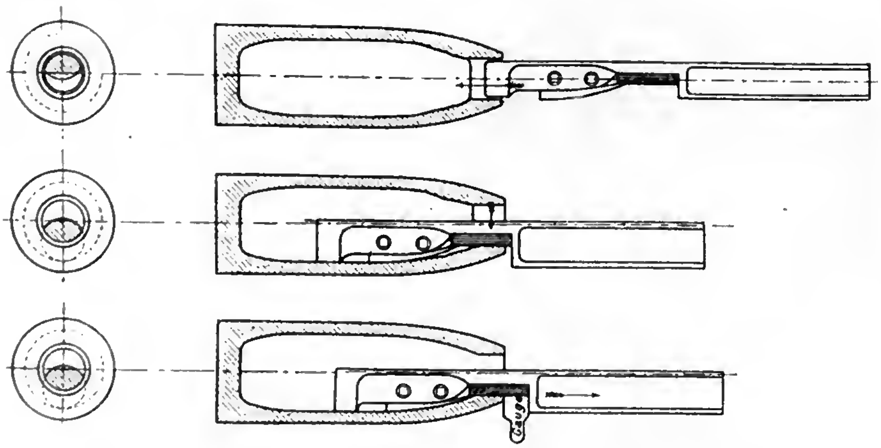

FIG. 6. APPLICATION OF BORING TOOL FOR INTERNAL RADII.

last fairly well, but with the thicker walled shells the wear on the die is very appreciable, the inside becoming gouged out, as shown by the dotted lines at A; the die is consequently spoiled.

To obviate this trouble some makers line the top die with chilled cast iron bushes, which prevent the wear due to the gouging action, but the chilled bushes frequently break owing to the cooling by water between the "heats." The spigot B has also been known to break off before the lining was worn out. To overcome these trobules, the spigot B has been abandoned and the dies made as shown in Fig. 8. The strengthening hoop D has been lowered so as to encircle the bottom die and serves instead of the spigot. The chilled

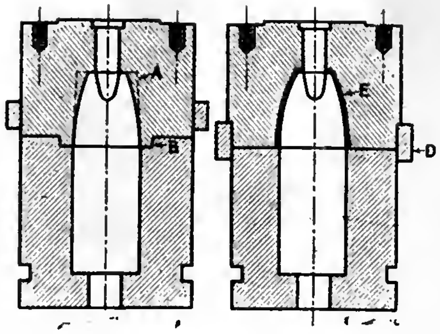

FIG. 7. FIG. 8.

conical hole E in the top die is made with ample metal around it to prevent water cracks, and the face is thoroughly chilled to a good depth.

THRIFT AND PRODUCTION CAMPAIGN

THE Dominion Government is starting an extensive campaign for the promotion of thrift and production in Canada. The principle of saving and thrift for the individual male and female is to be inculcated through a series of newspaper articles published throughout Canada with a view to putting the nation as a whole in a better position to bear the stress of war and to furnish the sinews of war for the cause of the Allies. The principle of production of new wealth from the land is to be similarly inculated, along the lines adopted last year, which tended to produce the record crops and which has enabled Canada to do more than ever before towards furnishing food supplies for export for the benefit of the Allies. A considerable sum of money has been voted by the Cabinet for the advance campaign which is to be conducted under the joint auspices of the Agricultural and Finance Departments.

The advertisements will be placed with newspapers throughout Canada, starting at once, through the King's Printer, who will furnish to each newspaper the necessary material. The same system will be adopted as was adopted in advancing the domestic loan of last autumn. The Government's statement in announcing the campaign is that there will be no distinction of polities made in placing advertisements.

WOMEN IN OXY-ACETYLENE WELDING

OXY-ACETYLENE welding is the latest work to attract female labor in England, an industry itself in its early stages. The success in the introduction of women into British industries and vocations calling for much skill has been remarkable in the last eighteen months, remarks an English paper, and every day seems to bring a fresh surprise in this direction. Ever since the active service branch of the National Union of Women's Suffrage Societies was formed, it has kept to the fore a programme of practical effort, and last September the first school for teaching of welding to women was opened. Six weeks' training is usually enough to equip a girl to take her place in a plant. Even before the war there was not an abundance of men doing this work, for the temptation with them when they had attained proficiency was to go to the still better paid work of cutting metal with oxygen.

G. G. Bramhill, district representative of the Ontario Department of Agriculture in Lambton County, has been appointed flax expert in the Federal Department of Agriculture. Mr. Bramhill will familiarize himself with the whole flax question in Canada, carry on investigation work in connection with fibre production, fibre manipulation and grading, and with the utilization of the straw where flax is grown for the grain, as in Western Canada.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

COMBINATION FILING MACHINE AND HACKSAW

THE Simplex Combination Bench Filer and Metal Hacksaw is a machine designed to take the place of hand filing and drill work, such as is required in making dies and similar work. The machine somewhat resembles the bench type of sensitive drill, the spindle and its driving gear being replaced by a vertical ram which is reciprocated by an oscillating arm driven by an adjustable crank disc.

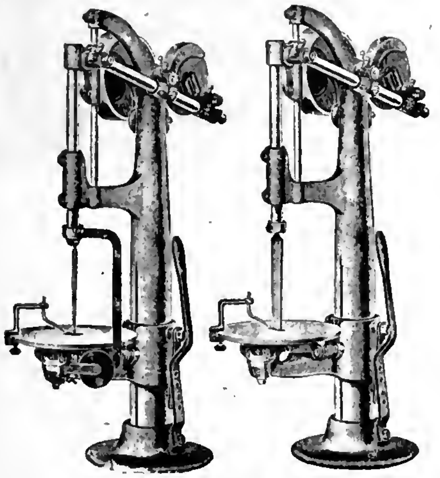

FIG. 1.—MACHINE ARRANGED AS HACK SAW AND FILER

Two views of the machine are shown in Fig. 1., as a metal hacksaw, and as a filing machine. The saw or file is driven rapidly with a vertical movement, the cut being on the down stroke so that no burr is turned over the line thus enabling the operator to file right up to the line without obscuring it. The filings are also discharged below the work where there is no mechanism to be damaged; all bearings are above the file where it is impossible for filings to get into them and cause wear.

The table is rapidly raised and lowered by the hand lever at the side, adjusting holes in the lever allowing the working height to be altered to suit the

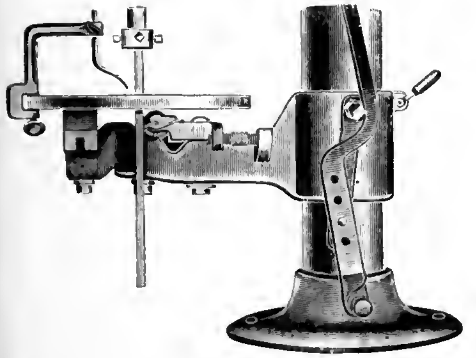

FIG. 2.—TABLE ELEVATED TO WORKING POSITION

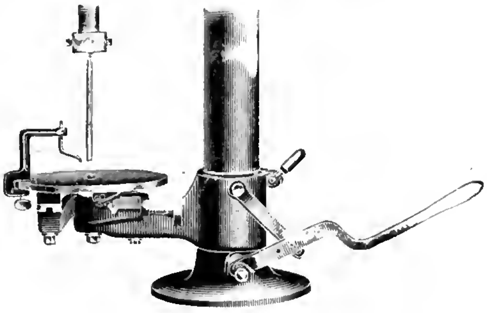

FIG. 3.—TABLE LOWERED FOR REMOVING WORK

condition of the file surface. Fig. 2 shows the table in working position, the side thrust being taken by a soft steel guide roller back of the file, while the bracket clamped to the edge of the table carries an adjustable hold-down. Fig. 3 shows the table lowered enabling the operator to remove or replace work without changing the position of file, hold-down, or guide roller.

The machine is fitted with a hack-saw frame taking 9 in. blades, which can be attached to the ram in a few seconds. This attachment is very desirable for cutting out model and die work, being particularly adapted for turning sharp curves. A sample of this work is shown in Fig. 4, the time required for the sawn hole being 18 minutes against 50 minutes for the drilled hole.

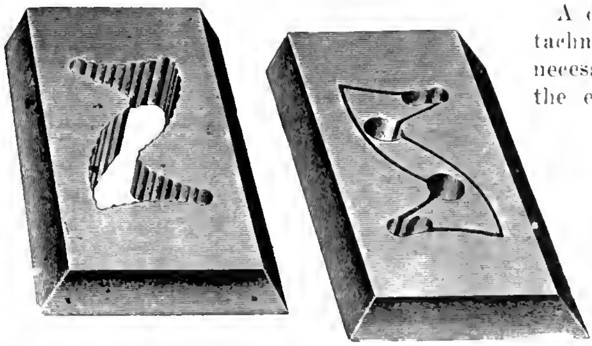

FIG. 4.—SHOWING DIFFERENCE IN WORK DUE TO USE OF SAWING ATTACHMENT FOR DIE MAKING.

Graduated plates enable the table to be tilted in either direction to any desired angle up to 20 degrees forward, 15 degrees either side, and 10 degrees back. The table is 10 in. diameter, and stroke is adjustable from 0 in. up to 6 in.

The builders of this machine are the Extensive Mfg. Co., New York, N.Y., who supply it with complete equipment including countershaft, belt shifter, wrenches and various attachments.

DIRECT READING PLATFORM INDICATOR

TO eliminate the handling of various weights ordinarily experienced in the weighing of large quantities of material, and at the same time increase the accuracy of results, the Canadian Fairbanks-Morse Co., have placed upon the market a direct reading Dial Indicator, which can be readily applied to any existing platform scale.

DIAL INDICATOR APPLICATION TO PLATFORM SCALE.

A distinctive feature of this attachment is the absence of any necessity for calculation to obtain the exact reading. The correct weight is automatically indicated on the dial, the instant the load is placed upon the platform. An internal view of the indicator is here shown, illustrating the general construction of the operating mechanism. The device is built along the lines of the ordinary beam scale, the beam being inside the case. Attached to this beam by means of lugs extending through slots in the case, is a graduated bar with poise (used only for taking tare of trucks or other containers). It offers also the further advantage of allowing hand weighing up to the full capacity of the dial, but is entirely independent of the dial. This construction thus permits of two accurate and independent systems of weighing.

The principle of the inclination balance is employed to furnish the resistance necessary to counterbalance loads up to the initial capacity of the dial, the main pendulum (E) being accurately sealed to the beam. In addition, the compensating pendulum (F) provides a further safeguard against change of balance due to scale being out of level or indicator out of plumb.

Vibration of the indicator is effectively prevented by an oil shock absorber with aluminum plunger attached to the end of the beam. Ample clearance is allowed to avoid undue friction.

Each indicator is fitted with a slotted shelf lever to transmit the load from the lever system to the dial, by means of which the dial is easily adapted to different types of scales.

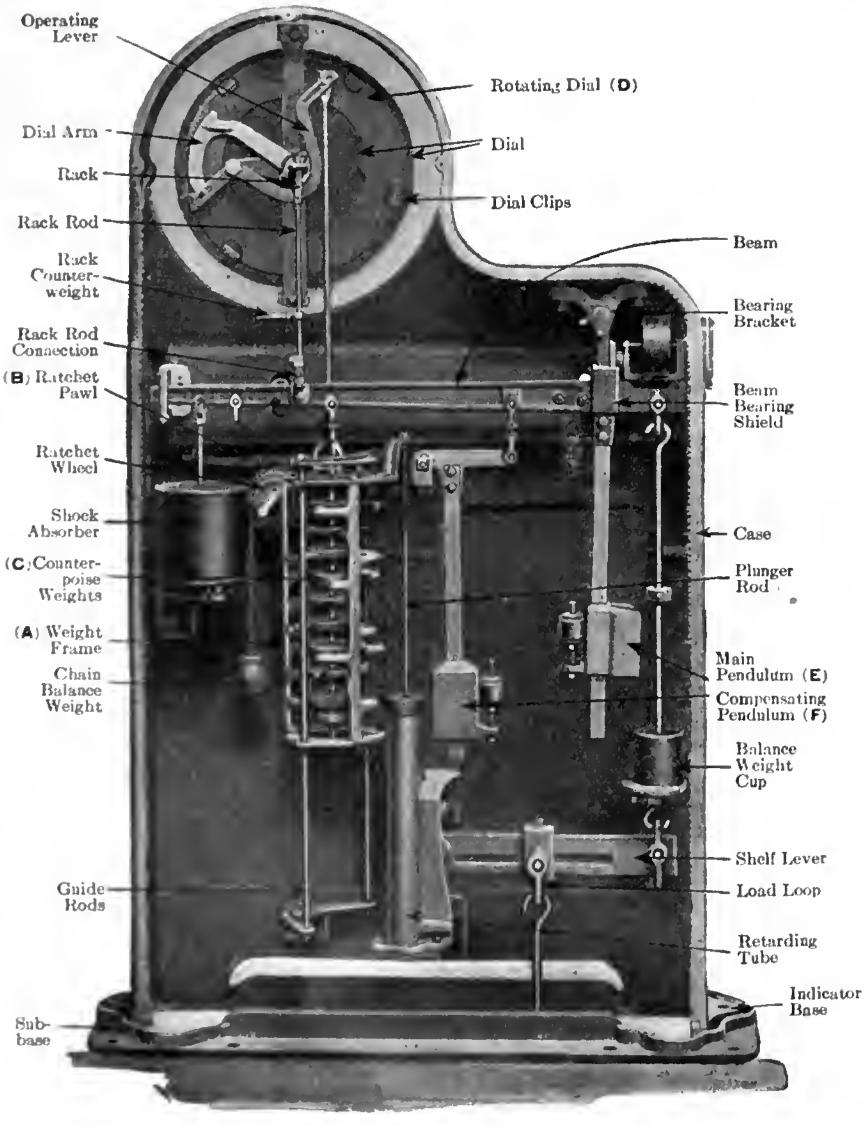
The iron case containing the dial parts is of exceptional heavy and rigid construction, to ensure permanent correct relation of the dial mechanism to the scale levers.

The base of the case has convenient leveling screws at the front. This base rests upon a separate outer iron base, the latter being securely bolted to the foundation, the entire setting thus providing simple means for proper alignment.

Supplementing the graduated dial is the weight frame (A), and counterpoise, carrying nine weights, each of which has the same value as the initial dial capacity, so that the total capacity of the indicator is ten times the capacity of the primary dial.

When the load is placed on the platform the shelf lever is depressed, thus raising the beam and also the rack rod which operates the pinion secured to the indicator hand. If the weight exceeds the registration on the initial dial and the hand travels beyond the final graduation, a button at the front of the stand, attached to the ratchet pawl (B), is pressed down, releasing the ratchet wheel, and allowing the weight frame (A) to lower, thus depositing weights at intervals until the indicating hand returns to the graduated section of the dial. As each weight is deposited on the counter-poise, the rotating dial is revolved and corresponding figures are shown through openings in the primary dial. By this means the correct reading is automatically recorded for all weights within the capacity of the machine.

FRONT VIEW OF DIAL INDICATOR.



DIAL INDICATOR INTERIOR SHOWING CONSTRUCTIONAL DETAIL.

These dial indicators are made in two sizes, one with a maximum capacity of 2,000 lbs., and the other with a capacity of 10,000 lbs. However, owing to the unique method of obtaining full capacity on the dial, the scale can readily be made of any required capacity.

WILL MAKE TOYS IN CANADA

THE Toy Buyers' Association was formed at a meeting of toy manufacturers and toy buyers at the Toy Exhibition in the Royal Bank building, Toronto, on March 30. The following committee was appointed: P. H. O'Neil, of the T. Eaton Co., Toronto, president; J. A. Wade, of the Consolidated Rubber Co., Montreal, vice-president; John A. Chantler of John A. Chantler & Co., second vice-president; L. G. Beebe, secretary-treasurer; L. V. Dusseau, of Gendron Manufacturing Co., Toronto; L. C. Fortin Duchesneau & Duchesneau, Montreal; Arthur P. Reed, of the Copp Clark Co., Toronto; W. G. Botsworth, of the United Incandescent Light Co., Toronto; Mr. M. E. Cone, of the Dominion Toy Co., Toronto. The design of a maple leaf with "Made-in-Canada" stamped in the centre has been selected.

EXPORT TRADE DEVELOPMENT

AN interesting feature relative to the development of American export trade, and incidentally that of the home market is the appeal by the United States Bureau of Foreign and Domestic Commerce for young, high-grade men whose education and natural ability fit them for service abroad. It is realized that nothing will contribute so effectively to the efficiency of the Bureau in the matter of aiding manufacturers to establish new connections and make those already formed more progressively valuable, than through the above indicated medium. As showing the urgency with which the immediate situation is viewed, and the highly sanguine achievement expectations formed of the scheme, it is desired that young men in large numbers present themselves at the Civil Service Examinations on April 5, the purposes of which are the selection of clerks for service with Commercial Attaches in foreign countries, and for service in the Bureau of Foreign and Domestic Commerce at home. The knowledge of one or more foreign languages is made an essential, and the salaries for appointments abroad are stated as being $1,500 per annum.

Canada, as well as the United States, is interested in establishing and building up an export trade. Her Attaches abroad—Trade Commissioners, are for the most part, however, located in Great Britain or in Colonies of the Empire, but the time has arrived when she too must "lengthen her cords and strengthen her stakes" by taking action along lines very similar to those of our Southern neighbors. Something more than the administrative and business activities of our Department of Trade and Commerce are called for at this juncture, and either in co-operation therewith or on their own initiative should our Canadian manufacturers in a corporate capacity take the requisite step. The scheme launched by the United States Bureau of Foreign and Domestic Commerce is worth appropriating.

LAKE MARINER SHORTAGE

IN the realm of shipping as in those of the farm and the workshop, labor scarcity is causing considerable anxiety. Canadian marine interests find the situation meantime so acute, that to protect themselves in the matter of the coming season's business on our Great Lakes, a recruiting office for mariners must needs be established in Toronto at least. Bottoms are of course much less plentiful than in pre-war years, due to so many lake craft having been transferred to ocean and ocean coasting services, nevertheless, it appears that crews are still less plentiful, due to enlistments for overseas service in one or other of the many battalions organized or in process.

Prospects for season 1916 are particularly bright for lake freight transportation, and as many contracts have already been negotiated, it is but reasonable to infer that a shortage in crew complement will not only prove a serious handicap in taking full advantage of the season's activities, but is likely to involve shipowners in losses more or less large. As we understand the situation, the shortage is largely that of sailors, the deck officers and engineers being for the most part again available. Sailors have their place of relative importance on every ship, and a considerable degree of competence in the discharge of their multifarious duties is required, on which latter account we can readily appreciate the vessel owners' present anxiety.

NATIONAL FAIRS AND NATIONAL BUSINESS

THE Second British Industries Fair was held from Feb. 21 to Mar. 3 in the Victoria and Albert Museum, London, Eng. In drawing the attention of Canadian firms to this event, emphasis is laid on the object of these Fairs which are to be of annual occurrence and destined to be of great assistance in furthering British trade interests.

The object is to bring manufacturers into contact with buyers for the home and overseas markets, and thus assist the former to capture the trade in certain products previously supplied by Germany. The first Fair which was held a year ago was organized by the British Board of Trade, and the results were so satisfactory that the exhibitors urged that body to assume control of future functions.

The importance of such an event will be understood when it is stated that admission was by invitation of the Board of Trade only, and was confined to bona fide buyers for home and overseas markets, this restriction of admission emphasizing the fact that the Fair was organized for business pure and simple.

While we do not wish to appear as advocating anything like an abandonment of amusement at the Canadian National Exhibition, we do wish to point out the desirability of every Canadian manufacturer exhibiting his product more extensively and intensively than ever before. The Exhibition authorities can be relied upon to give the usual publicity to the event, and the Department of Trade and Commerce through their Commissioners should see that foreign buyers are advised of the event in time to include it in their itinerary.

The Canadian Exhibition, however, is broader in its scope than the British Fair referred to, which was confined to toys and games; earthenware, porcelain and china; glass goods; fancy goods; and stationery, etc., and the wider field here only makes it more desirable that every line of industry be represented more strongly than before. The value of the efforts being made by the Department of Trade and Commerce on behalf of our manufacturers could be admirably demonstrated by the establishment of a Bureau at the Exhibition where samples and catalogues at present in Ottawa would be available to interested parties. The opportunity for examining these articles would be welcomed and accepted by numerous parties who otherwise might not be able to make a special journey to Ottawa, and the present awakening of Canadian interest in overseas trade would receive an impetus which will be invaluable during the world-wide competition of the near future.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., April 3, 1916.—No feature of special interest has developed in the industrial situation, and conditions seem to be quietly adjusting themselves to the opening of spring and summer business. The high cost of materials will undoubtedly have considerable effect on the volume of domestic business taken up this year. While present abnormal conditions prevail it is very unlikely that any but urgent necessities will be undertaken. Even if prices were no objection, the extraordinary war situation leaves little prospect of obtaining material for domestic purposes.

Pig Iron

The pig iron situation, while apparently unchanged, is nevertheless assuming a position where higher prices may be expected. The demand is as great as ever, and the supply does not appear to exceed the requirements of the steel makers. There is at present no visible shortage, but stock supplies are gradually decreasing. Considerable difficulty has been experienced by the inability to secure shipments of raw material, owing to the congested condition of railroad facilities.

Locally, the situation is unchanged and prices are firm.

Steel

The general industrial situation is showing signs of steadying down, and a quieter feeling seems to prevail throughout the steel and iron market. Future demand is not so pronounced, and consumers are not anxious to place further orders at present prices for material they will not require for many months. While this may be some indication of an easier market, the mills are showing no uneasiness, as they welcome the relief it offers. Producers are filled up for the balance of the year, and the pressure for delivery is still very great. The feeling is abroad that prices have about reached the high level, and the general interests are waiting for further developments. Reports from the Pittsburg district intimate that it is now possible to secure certain material from sources that a month ago were unable to book orders. Pittsburg quotations on open-hearth billets have advanced $5 a ton, being quoted at $50. Forging billets show a similar increase, this week's price being $75 a ton. Steel bars, Pittsburg, are higher by ¼c, being quoted at 3¼c. Structural shapes have advanced 25c per hundred, and this week's price is $2.75. The sheet mills are practically sold out on blue annealed sheet for the remainder of the year, but light black and galvanized can be contracted for, on three or four months' delivery. Chicago prices on blue annealed sheets are now quoted at 3.189c, or an advance of 1c over the previous week. Steel pipe shows an advance, the discount being 72 per cent. in place of 73. Wrought iron pipe shows a similar advance, the present discount being 62 per cent. Pittsburg spike prices are higher; railroad quoted at $2.75 and small at $3 per hundred.

Metals

The week has been comparatively quiet in all metals during the past week, but indications of activity are apparent from conditions which are now developing. Copper is taking on strength after a period of dullness, and prices are expected to again advance. Tin is in greater demand, and consumers are continually making inquiries. Lead has become stronger, following an advance of Trust prices. Spelter is quiet, with the supply greater than present demand.

Copper.—The copper situation is again showing signs of a further upward movement. Large purchases are reported, following a heavy demand for future metal. Both the home consumers and foreign buyers are making inquiries for large quantities of metal. If recent inquiries develop into purchases it is more than likely that prices will be advanced by producers to protect their future supply. London reports an advane of £2 10s. on spot and £3 on futures. This additional advance over that of last week is largely owing to an apparent copper shortage developing in Great Britain. The prospects are that the British requirements this year will be far greater than the present supply will take care of, and the indications point to yet higher prices in copper. The copper interests in the States, however, have not yet been affected by the recent developments in the foreign situation; in fact, some producers are quoting slightly easier figures, but intimate that prevailing conditions will ultimately cause a further advance. Local conditions are unchanged, and prices are firm

at 31c for lake and electrolytic, and 30c for castings.

Tin.—Heavy consumption and continued demand still feature the tin situation. It is reported that some dealers have been unable to fill contracts, and are making strong efforts to buy tin to accommodate customers. The difficulty of securing supply is responsible for premiums being placed on nearby metal. It is thought that consumption will be still greater during the next few months. Nearby and early futures are firm and active, while far futures are somewhat easier, in anticipation of a lower market. London quotations are 15s. lower, and prices on Straits tin have declined £2. The New York markets are quoting a nominal price of $49.25, a reduction of three-quarters of a cent. Local dealers have advanced their prices 1c per pound, this week's price being 51c per pound.

Spelter.—Several unlooked-for sources of supply have recently developed. The production has apparently increased to such an extent that a shortage of metal seems very unlikely at the present time, and prices are expected to remain firm unless an exceptionally heavy demand is made for additional metal. This will possibly show itself shortly, for previous activity in copper has also affected the spelter situation, as brass interests are more or less concerned in both metals. London has advanced prices on spot £3 per ton, but conditions here are practically unchanged and prices are firm at 23c per pound.

Lead.—The leading lead interests are still controlling the market by maintaining a lower price than outside interests. They are evidently holding to the belief that the domestic consumer should be protected from any unnecessary advance in prices, due to extraordinary war conditions. However, the recent action of the Trust in placing an additional half cent on their quotation has had much to do with the present strength of the market. The decline noted last week on the New York market has been changed to a similar advance, and the outside interests are again quoting 8⅛c. The Trust price is now 7½c per pound. London prices are easier, and a decline of 10s. is noted on spot and 8s on futures. Local prices are firm and unchanged at 10c per pound.

Antimony.—The situation is a little stronger, with increased demand, but quotations are holding firm at 48c.

Aluminum.—The market is a little stronger in the States, and prices show a slight advance, but local conditions are unchanged, with prices firm at 68c.

Machine Tools and Supplies

The machine tool industry is gradually assuming normal conditions, and the demand for munitions equipment is constantly falling off, but in several cases firms are still engaged in filling orders for shell equipment. However, the bulk of this class of tools have now been placed, and with the exception of a few scattered orders, it is not expected that any great demand will be made along these lines. The domestic requirements, while not large, are continually improving, and future developments may put the machine tool business more on a normal basis. During the past year or more many new lines of manufactured articles and processes have been placed before the Canadian manufacturers, and with those which have been developed, and also those now under consideration, the prospects are that renewed activity for necessary equipment will soon be evident in machine tool plants.

Old Materials

The market in scrap metals has been quiet during the past week and heavy sales have been few. Prices, however, are very firm, remaining unchanged, with some showing slight advances. Brass clippings and turnings show an advance of ½c, this week's price being 16c and 11¾c respectively. Aluminum is in good demand, and dealers are asking 36c, an advance of 1c per pound. Scrap zinc is easier at a decline of ¾c, being quoted at 15c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Toronto, Ont., April 4.—A gratifying feature of the industrial situation is the steady improvement in domestic business due to the prosperous condition of the country. The outlook for an increase in the export business, other than munitions and war supplies, has improved considerably and manufacturers are looking for important developments. The spring weather has had a stimulating effect on some industries and the outlook generally is distinctly favorable. Navigation will be open on the Lakes for the season very shortly which will considerably relieve the congestion of freight on the railways. The situation in this regard is getting more acute and has caused considerable delay to shipments and inconvenience to merchants. The customs returns for Toronto for the fiscal year which ended on March 31, are almost two million dollars in excess of the greatest previous year in the history of the port. These has been a very marked gain in revenue since September, and March showed the largest increase for any month.

Manufacturers are becoming concerned over the shortage of labor which is the beginning to be felt, and which will become more serious as the number of battalions increases. The shortage of raw materials is becoming a serious question for manufacturers to contend with, and prices are still rising, thus increasing the cost of production. The upward trend in prices of finished products continues, a number of advances having been made during the week. The most important of these are carbon drills and reamers, shafting, copper rivets, cap and set screws, and kindred lines.

Steel Market

The market continues strong and prices are still moving upward. The opinion is held in some circles that the high point for prices has probably been reached or nearly so, but at the same time a recession in quotations is not expected for a long time to come. The fact that the steel mills have all the business they can take care of this year will have a tendency to steady the market and prevent any marked decline. Steel companies are making strenuous efforts to develop their export business and considerable success in this direction in anticipated. The mills continue to be actively engaged in the production of steel for shells, the demand still being very insistent. Export business is developing and there has recently been a noticeable improvement in the domestic demand.

An advance in steel shafting has been announced, the new price being list plus 20 per cent. at warehouse, and list plus 10 per cent. at mill. The market for boiler tubes is very firm and an advance in prices is looked for. Tube mills are sold up for four or five months, consequently deliveries are very backward. Prices on boiler plates are firm and a further advance is expected owing to the sold-up condition of the plate mills. Prices of wrought iron and galvanized pipe have advanced in the States and a similiar movement may take place here. Steel bars are firm and unchanged at $3, and iron bars at $2.75 per 100 lbs.

The galvanized sheet situation is unchanged and the market continues very firm. The uncertainties of the spelter market and high prices are not attractive to the galvanizers who are also confronted with increasing prices on black sheets. The demand for black sheets in the primary market is on the increase and many mills are well sold ahead. In some cases orders now on the books run well into the fourth quarter. Quot-

ations locally on black sheets are firm and unchanged.

The steel market in the United States is very strong and prices still have an upward tendency. It is believed in some quarters however that the top of the market has probably nearly been reached and that prices will remain at the high level for some considerable time. The larger steel companies are booked up for the rest of the year and some inquiries have been received for 1917 delivery. Steel bars are unchanged at 2.75c, plates 3.50c, and shapes 2.50c f.o.b. Pittsburgh. Prices of semi-finished steel products are very firm and will probably advance. Billets are now in great demand but prices are unchanged. No wire rods for the open market can be had from Pttsburgh mills, and quotations are very firm at $57 per ton.

Pig Iron

The market is very firm and the general situation is unchanged. Indications point to very heavy consumption this year of steel making grades of pig iron. The Nova Scotia Steel & Coal Co., propose building a new blast furnace at their plant at Sydney Mines, C. B.

Old Metals

There is no change in the situation and quotations are practically the same as last week. All copper scrap is in good demand and prices firm. There is a good demand for heavy melting steel and the market is strong. Old lead is strong in sympathy with the pig lead market, but prices are unchanged.

Machine Tools

The market is fairly active, the bulk of the business in machine tools being for munition plants. Canadian machine tool makers continue busy turning out lathes and also special tools for machining shells. Deliveries from U.S. makers have not improved and are still very backward especially on standard tools.

Supplies

A good demand is reported for machine shop supplies, buying being generally of the hand-to-mouth type. Prices continue to advance, the most important change this week being the new discounts on carbon drills and reamers which have advanced about 10 per cent. New discounts are also given this week on cap and set screws, nuts, etc. Turpentine has advenced 1c and is now quoted at 80c per gallon. Prices of wool packing waste and washed wipers have been withdrawn and are only on application. This step has been taken on account of the great scarcity of wool yarns and cotton rags. The market is very strong and an advance in white and colored waste is expected in the near future owing to the scarcity and increase in cost of cotton threads.

Metals

The most interesting feature to note in the metal markets this week is another advance in lead, otherwise prices are at about the same level as last week. Stocks of all metals are low in Toronto and prices on the local market are very sensitive. Business is very good having improved considerably during the past few weeks. The copper market is stronger due to a large buying movement which may result in higher prices. Tin is also strong and may possibly advance. The lead market is strong and higher after a period of comparative dulness. The antimony and aluminum markets are strong with nominal quotations. Solders are unchanged but very firm and higher prices are very probable.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Col. N. Golejewski, Military Attache, Room 904, Flatiron Building, New York City, N.Y.

Copper.—An active demand for copper has developed into a strong buying movement and there is every possibility of higher prices. The consumption of copper in Europe is said to be far in advance of the present shipping facilities and an urgent need exists for this metal. There is also an abnormal demand for spot copper in the States but very little is available. The local market is strong with quotations unchanged and nominal at 30½c per pound.

Tin.—The market is easier in London but firm and unchanged at New York. The outstanding features in the tin situation continue to be heavy consumption and difficulty of getting supplies. The New York market is still affected by the delays attending the granting of licenses permitting exports of metal from England. The situation is rather tight and higher prices may be looked for. Quotations are unchanged and nominal at 53c per pound.

Spelter.—The market is more active and firmer. It is possible that the buying movement which has already started in copper may extend to spelter as both metals are used together at the brass mills. Production has been greatly increased and it is doubtful if prices can go much higher unless some extraordinary demand develops. The market is firm at 22c per pound.

Lead. — The "Trust" has again advanced prices of lead and is quoting at 7.50c New York. The outside market is higher still, the price ranging from 7.87c to 8.12c. The market is very strong and the demand continues heavy with a scarcity of spot metal. Lead has advanced ½c and is now quoted at 11c per pound.

Antimony.—The market is strong and the demand is heavy but supplies are scarce. Quotations are nominal and unchanged at 48c per pound.

Aluminum.—The situation is unchanged and the market is strong at 68c per pound.

Solders.—Prices are very firm and an advance is not unlikely owing to the continued strength in the tin and lead market. Guaranteed is quoted at 31½c and strictly at 29c per pound.

NOVA SCOTIA STEEL & COAL CO.

SELDOM has such widespread interest been manifested in any meeting of the Nova Scotia Steel & Coal Co., as was shown in the recent annual meeting of shareholders. It was known that the company had had a most successful year and besides a number of important announcements were looked for. Col. Thomas Cantley President and General Manager presided and in moving the adoption of the directors' report and statement of accounts, Col. Cantley said in part:—

"During the past thirty odd years with which I have had the privilege of being connected with the Scotia Company, the corporation and its management have passed through some anxious and trying years, but in all my experience I cannot recall a year where the issue involved in the fluctuations and departure from normal conditions were anything like so great as during 1915.

Iron and Steel Trade

"In last year's report reference was made to the depressed conditions of the iron and steel trade as experienced for the great part of that year and which reached a crisis with the outbreak of the great war at the beginning of August and for two months following largely paralyzed the ordinary activities of the company. It was only during the last few weeks of that calendar year, (1914), that any improvement was manifested when certain munition work was

undertaken and some two hundred thousand shrapnel shell bodies were produced at the New Glasgow plant. That report pointed out that when the year closed the Company had been entrusted with ordnance material orders sufficient to keep the plant fully occupied for the first six months of the year, 1915.

"The additional forging presses and other plant requisites for the execution of the very considerable order then entrusted to the Company were installed as rapidly as possible. Equipment for the finishing and assembling of shrapnel shells was also then installed. This was followed in May by building and equipping a second finishing department for machining and assembling 4.5 and 60 pounder high explosive shells. For the calendar year, 1915, there was manufactured in the Company's forges nearly three million of shell bodies, comprising four different sizes of shrapnel and high explosive shells. During the closing months of 1915 we contracted for a further large tonnage of shell forgings, including large sizes than have hitherto been made in the Dominion.

To enable us to undertake this munition work it was decided to install a further unit of larger and more powerful presses, for forging shells up to 19 inch. diameter. Orders for the necessary presses, accumulators, pumps, boilers and other plant have been placed and the foundation for this machinery is now all in place. The buildings erected are practically completed, some other plant is already on the ground and the balance will be installed as soon as we can get delivery, and it is expected that within a few weeks we will be turning out a considerable tonnage of large shells.

To aid in providing the large additional quantity of steel required to fill the contracts referred to, the directors in November last decided on an additional sixty-ton open-hearth furnace at Sydney Mines and this furnace was actually producing steel within four months from the date of that decision, which, under existing conditions, we considered good work. The iron and operations were considerably greater than in 1914, and were as follows:—Coke made 90,277 tons, limestone and dolomite quarried 79,211 tons, pig iron made 73,110 tons, steel ingots made at Sydney Mines 97,072 tons. Steel billets rolled at New Glasgow 76,082 tons, total shipments of finished steel forgings from New Glasgow plants being 62,283 tons.

Coal Trade

"Owing to the great shortage of suitable steamers for transportation, the abnormally high cost of shipping and shortage of skilled labor, due to enlistments, mining was not proceeded with as vigorously as in former years, the total coal mined being 618,103 tons, or 134,050 tons less than the previous year. Of this tonnage there was used in the manufacture of iron and steel and other plants of the company 284,971 tons, or 110,323 tons more than the previous year.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Hamilton, Ont.—The Canada Wire & Iron Goods Co. will build an addition to their plant.

Berlin, Ont.—The Canadian Regal Motor Co., will build a factory here to cost about $18,000.

Berlin, Ont.— Fire damaged the premises of the Forwell Foundry Co., and caused a loss of $5,000.

Midland, Ont.—D. G. Dobson, is in the market for a heavy duty gasoline or oil marine engine of 40 to 60 h.p.

Hamilton, Ont. — The Steel Co., of Canada, will build an addition to its plant, estimated to cost $24,000.

Coaticook, Que.—An addition will be built to the plant of the Belding Paul-Corticelli, Ltd., and new machinery installed.

Winnipeg, Man.—The Greater Winnipeg Water District Board have approved of alterations to the pipe line now under construction.

Niagara, Falls, Ont.—The Perfection Tire & Motor Co., of Fort Madison, Iowa, will have plans prepared for a factory to be erected here.

Brockville, Ont.—The Canada Foundries & Forgings Co., will make an extension to their plant here to take care of increasing business.

Guelph, Ont. — A company propose building a stove factory here at an approximate cost of $7,000. W. A. Mahoney of this city is the architect.

Thornburg, Ont. — The Standard Chemical Co., will build an addition to its plant and install two new ovens. Construction work will be started immediately.

Windsor Ont. — The Maxwell Motor Co., will begin building operations immediately on the new plant here. The initial unit will be 100 ft. x 300 ft. and will cost $65,000.

Kingston, Ont.—A Davis & Son, Ltd., is in the market for a gap lathe, 16 in. x 15 ft., to swing 30 in. in the gap, with countershaft, chuck, steady rest compound rest and screw-cutting gear attached.

Halifax, N.S.—At a meeting of the Board of Directors, of the Nova Scotia & Coal Co., it was decided to proceed at once with the erection of another blast furnace at Sydney Mines, to cost from $200,000 to $300,000.

Winnipeg, Man.—The Baldwin Mfg. Co., which has juse secured a charter and is capitalized at $1,000,000, will erect a plant here for the manufacture of grain threshers. G. L. Constable, of Winnipeg, is president.

Fredericton, N.B. — The Fredericton Gaslight Co., has about completed arrangements for the extension of their lines to the east side of the St. John River. The company intends to expend between $25,000 and $30,000 in this projected work.

St. John, N.B.—The Bay of Fundy Tide Power Co., which was recently incorporated will install a hydro-electric plant at Cape Split. The initial unit will be 10,000 h.p., but provision will be made for future development. George B. Cutten, of Acadia, N.S., is president of the company.

Municipal

Bow Island, Alta.—The town council propose spending $1,660 on public works and $1,725 on a natural gas lighting system.

Stratford, Ont.—There is now a probability that North Easthope Council may resubmit the hydro radial by-law, defeated by a large majority in January.

London, Ont.—The first unit of the new pumping plant has been installed at the Springbanks station. The entire plant is being overhauled and made more efficient.

Sarnia, Ont.—Owing to the serious water wastage through leaky mains it is proposed to have the system surveyed which would cost about $2,000. The loss through wastage is estimated at $25,000 a year.

Galt, Ont.—Two by-laws will be submitted to the ratepayers on April 28; one to raise $12,000 for the purchase of a motor fire engine, and the other to authorize an expenditure of $16,000 on a fire alarm system.

Saskatoon, Sask.—The city council propose to install the following works and equipment: Incinerator, $100,000; switchboard, $8,000; motor converter. $16,000; boiler feed pumps, $2,000, and completion of a water main, $28,000.

Highgate, Ont.—The Hydro-Electric Power Commission has advised that Highgate will be given first consideration in the construction of new lines.

Grand Valley, Ont.—A by-law has been carried authorizing the construction of a hydro electric system, at an approximate cost of $11,000.

Tenders

London, Ont.—Tenders will be received by the Board of Control, up to April 10, for a five-passenger car for fire department use, and 1,000 feet of 2½-inch cotton rubber-lined hose. John Aitken, fire chief.

Toronto, Ont.—Tenders will be received by the chairman, Board of Control, City Hall, Toronto, up to April 11, 1916, for the purchase from the city of the following: 200 long tons 30-pound rail; 20 only No. 5 x 30-pound switches. Specifications may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—The Board of Education will receive tenders up to April 11, 1916, for one motor for ice machine, two motors for ventilating fans, one motor and sump pump. Plans and specifications may be seen at the principal's office, Central Technical school, Lippincott street.

Calgary Alta.—Tenders sealed will be received until April 15, for the supply of all materials, tools and labor necessary for the construction of one to fourteen elevators. Plans and specifications can be obtained upon application to the Alberta. Farmers' Co-Operative Elevator Co., Calgary.

Hamilton, Ont.—Tenders addressed to the chairman Board of Control, will be received up to April 10, 1916, for the several works required in the erection of a Nurses' Home for the Mount Hamilton Hospital. Plans and specifications may be seen at the office of Stewart & Witton, architects, Hamilton.

Toronto, Ont.—Tenders will be received by the chairman, Board of Control, City Hall, up to April 11, for the supply and delivery of: Electrically operated driving gear for operating 36-inch gate valves, at main pumping station, John street. Specifications and forms of

24″ Standard Milwaukee Lathe for Finish Turning, Wave Grooving; Under Cutting, Band Turning and Rectifying

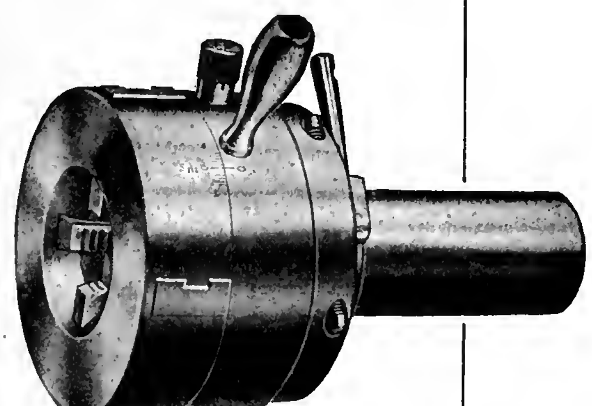
Countershaft should run ...	150
Net Weight with 10′ Bed..	5,000 lbs.

IMMEDIATE DELIVERY

The A. R. Williams Machinery Co. Limited
TORONTO CANADA

Give Him A Chance



Give the man who has to do the work a chance to say what tools give best results, and then give him the best.

Among all the users of Geometric threading dies, a dissatisfied man has not been found.

We have a Geometric Self-Opening and Adjustable Screw-Cutting Die Head for you, also, and want you to have it.

Geometric Die Heads can be arranged for use on any make of Screw Machine or Turret Lathe.

Let us know the requirements of your thread-cutting operations, and we will send you full particulars of the most suitable Die-Head.

The Geometric Tool Co.

tender may be obtained at the Works Department, Room 12, City Hall.

Quebec, Que.—Tenders for freight shed and grain galleries, will be received at the Quebec Harbor Commissioners' Office, Pointe-a-Carey Wharf, Quebec, up to April 15 next. Plans and specifications of the contemplated work may be seen at the harbor engineer's office, Pointe-a-Carey Wharf St. George Boswell, chief engineer.

Vancouver, B.C.—The British Columbian Fisheries, Ltd., will sell their entire plant and equipment, including buildings, machinery, tools, refrigerating plant, sawmill and machinery, fertilizer plant and equipment, power plant equipment, steam trawlers and scows, etc. Tenders will be received up to April 15, and full particulars may be obtained from James Keppel Ball, Yorkshire Building, Vancouver, B.C.

Collingwood, Ont.—Tenders will be received by the chairman of the Collingwood Water and Light Commission until April 11, for the following works—(1) Pumping machinery, comprising two motor-driven units, 1,000 Imperial gallons capacity each. (2) Pump well and connections. Plans and specifications may be seen at the office of the Chipman and Power Engineers, 204 Mail Building, Toronto, or at the office of the Water and Light Commission, Collingwood. Hugh A. Currie, chairman.

General Industrial

The Vaudreuil Electric Co., of Vaudreuil, Que., has increased its capital stock to $200,000.

The Ontario Steel Products Co., Montreal, has received a new and remunerative order for springs.

Toronto Ont. — F. A. Hallman will build an addition to the factory on Logan Ave., at a cost of $1,000.

The Alaska Feather & Down Co., Montreal and Winnipeg has changed its name to the Parkhill Mfg. Co.

Brampton, Ont.—The Acme Rubber Co. propose to build a factory, at an approximate cost of $30,000, and a by-law will be submitted to the ratepayers.

New Incorporations

The Govan Motor & Machine Co., of Govan, Sask., has been incorporated with a capital of $20,000.

The Commercial Motor Bodies & Carriages, has been incorporated at Ottawa, with a capital of $40,000 to acquire and take over as a going concern the carriage and woodworking business of C. Kloepfer, Toronto, Ont.

The Gilson Manufacturing Co., has been incorporated at Ottawa with a capital of $150,000 to manufacture gasoline engines, etc., at Guelph, Ont. Incorporators: Edward Barelman, Walter Ellis Buckingham and Robert Kennedy Dawson, all of Guelph, Ont.

The Peerless Weaving & Belting Co. has been incorporated at Ottawa, with a capital of $150,000 to manufacture cotton and leather belting at Hamilton, Ont. Incorporators: Edward De Ette Matteson, Edward Frederick Gingras and Jacob iDlche, all of Buffalo, N.Y.

Silks Limited has been incorporated at Ottawa, with capital of $500,000 to manufacture silks and other textiles. Head office is at Toronto, Ont., and the incorporators are Joseph Powley, Geoffrey Adams and Edwin Smily, all of Toronto, Ont.

The Dominion Casket Co., has been incorporated at Ottawa, with capital of $100,000 to manufacture caskets, boxes, wagons, etc., at Guelph, Ont. Incorporators: William Pears, of Toronto, and Wm. George Whitehead, and James Mason Arnold of Guelph, Ont.

The Canadian China Clay Co., has been incorporated at Ottawa with a capital of $1,500,000 to develop minerals and other deposits. Head office Mintreal, Quebec. Incorporators: Francis George Bush, George Robert Denham and H. William Jackson, all of Montreal, Que.

The Great Lakes Power Co., has been incorporated at Toronto, Ont., with a capital of $2,600,000. To develop hydro-electric steam or other power. Head office at Sault Ste Marie, Ont. Incorporators, John Alexander McPhail and William Eberts Brown of Toronto.

The Hall Motors Ltd., has been incorporated at Toronto, Ont., with a capital of $40,000 to manufacture automobiles, motor cycles and bicycles with head office at Toronto, Ont. Incorporators, Robert Halls Vankempen, Adam Blackhall Mitchel and William M. Hall all of Toronto.

The London Creamery, Ltd., has been incorporated at Toronto, Ont., with a capital of $40,000 to manufacture condensed, preserved and evaporated milk, with head office at Toronto, Ont. Incorporators, Albert Weber Vale, Ralph Turnbull Francis and John Mitchell all of Toronto.

The Standard Milk Products, Ltd., has been incorporated at Toronto, Ont., with a capital of $150,000 to manufacture condensed and evaporated milk. Head office at Toronto, Ont. Incorporators, Harold Leslie Grimshaw, Edward John Swift and Edward B. De Camps all of Toronto.

The Pierrefonds Electric Co., has been incorporated at Ottawa, with a capital of $50,000 to carry on the business of an electric light, heat and power company, at Ste. Genevieve de Pierrefonds, Que. Incorporators: Joseph Bernard, George St. Germaine and Napoleon Nantel, all of Montreal, Que.

The Iron Works, has been incorporated at Ottawa, with a capital of $96,000 to carry on a general foundry, boiler and machine shop business at Owen Sound, Ont. Incorporators: Frances Howard Kilbourn, John McEwen and Samuel A. McDougall, all of Owen Sound.

The Boico Company has been incorporated at Toronto, Ont., with a capital of $40,000 to carry on the business of mechanical hydraulic and civil engineers and contractors with head office at Toronto, Ont. Incorporators, Joseph Max Bullen, Harold Learoyd Steele and Francis H. Hurley all of Toronto.

The International Molybdenum Co. has been incorporated at Ottawa, with a capital of $5,000,000 to develop, refine and otherwise treat ores, metals and minerals substances of all kinds, at Renfrew, Ont. Incorporators: Reginald Holland Parminter, Arthur John Thomson and William Symon Morloch, all of Toronto, Ont.

The Hudson Bay Zinc, Ltd., has been incorporated at Victoria, B.C., with a capitalization of $5,000,000, divided into 1,000,000 shares. The company is empowered to carry on a mining and smelting business and to purchase from Maurice W. Bacon and William E. Cullen, Jr., 14 mining claims situated in the Kootenay mining division. The Hudson's Bay Company has its headquarters at Salmo. Maurice W. Bacon and William E. Cullen, Jr., are at present associated with others in the operation of the Hudson Bay mine at Salmo, which it is believed will be the principal property to be controlled by the new company.

Contracts Awarded

Three Rivers, Que.—The general contract for the erection of an addition to the plant of the Canada Iron Corporation has been awarded to Loomis Dakin & Co., Sherbrooke, Que.

Winnipeg, Man.—The Economy Foundry Co., of Portage la Prairie, Man., has been awarded a $25,000 contract for ornamental ironwork by the T. Eaton

Co., in connection with the erection of the new buildings.

Victoria, B.C.—The city council has awarded contracts to the Dunlop Tire & Rubber Co., for chemical couplings; the Canadian Consolidated Rubber Co., for 1 in. and 1½ in. chemical hose; the Canadian Consolidated Rubber Co., Dunlop Tire & Rubber Co., and the Goodyear Tire Co., for 2½ in. fire hose, and the Northern Electric Co., for 6 miles of wire.

Trade Gossip

Rail Mills Busy.—The rail makers in Canada are reported to have opened their books covering deliveries for the first six months of 1917. Several thousand tons have been booked.

The International Nickel Co. has informed the Dominion Government of its intention to begin the erection of the Canadian plant immediately. The company is understood to have under consideration a site on the Atlantic coast somewhere in the vicinity of Halifax, although the exact details in regard to this have not been given.

The Canadian Westinghouse Co. of Hamilton, Ont., enjoyed a prosperous year, according to the reports submitted at the annual meeting held in Hamilton on March 29. The financial statement to December 31, of last year showed net earnings of $860,628. The company now has a surplus of $2,570,000 and is in a strong condition financially. A dividend of 9 per cent. was paid during the year. The following directors were elected: H. H. Westinghouse, L. A. Osborne, P. J. Myler, T. Ahearn, Sir John M. Gibson, J. F. Miller, W. Y. Soper, C. S. Sise, Chas. A. Terry and G. E. Cripp.

Granby Output. — Granby Consolidated Mining, Smelting & Power Co., in February produced 2,690,265 pounds of copper. Production for a series of months has been: February, 2,690,265 pounds; January, 3,122,879; December, 3,775,335; November, 3,575,974; October, 4,124,499; September, 4,119,337. Beginning with November, the production figures reflect the severe weather experienced, but output is now expected to show gradual improvement until the 4,000,000 pounds monthly mark is again attained.

Asbestos and Nickel Export.—A delegation of owners of asbestos mines waited on the Commissioner of Customs at Ottawa, on March 28, to inquire into the terms of the Order-in-Council prohibiting the export of nickel and asbestos to any but British possessions, the trade being uncertain as to whether the exportation under special license, which is to be allowed with regard to nickel, would also apply to the case of asbestos. An assurance was given that this is the case, and that licenses will be issued where the Government is satisfied as to the destination o fthe shipments.

Lumber for Freight Cars.—Europe is in the market for exceptionally large supplies of lumber, for freight car construction, and American lumber manufacturers have orders to ship up to 75,000,000 feet. This is exclusive of a big order placed by Russia for 40,000 cars last autumn. Requests include all types of freight cars, including several special types. Italy wants 2,000 box cars, and France 1,000 flat and 500 box cars, and 1,500 box car parts. A Nova Scotia concern received orders for 2,000 cars from the French Government, it is said, and the American Pressed Steel Car Co. gets an order for 50 box cars from China. Several more foreign orders are expected soon.

Great Freight Record.—A carload of freight every twenty-two seconds in the year—that is the remarkable record made by the Grand Trunk Railway system. During 1915 the Grand Trunk handled 1,376,189 carloads of freight, just about three cars every minute during the whole year. When it is stated that these cars, if gathered together, would make a train 10,416 miles in length—three times the distance be-

tween the Atlantic and Pacific oceans through Canada—some idea may be gained of what this railway is doing in handling the commerce of the Dominion. These figures are exclusive of the large amount of traffic handled by the Grand Trunk Pacific in Western Canada.

Paper Prices High.—Canadian paper makers are enjoying unprecedented prosperity, owing to the heavy demand for shipments abroad. As a consequence, Canadian consumers of stationery and general printed material are compelled to pay unusually high prices for their requirements, with prospects of very much increased prices over a period of the next few months. Ordinary calendered book paper (super-calendered book) has jumped in price from $5\frac{1}{4}$ to $6\frac{1}{2}$ cents per pound within the past week. Bond and other papers have advanced from 4 to 5 cents within the past two months. Newsprint also has advanced from $\frac{1}{2}$ to $\frac{3}{4}$ cent a pound to new buyers. Kraft is selling for export at 10 cents, compared with 4 cents a few months ago. The trade state that the cause is due to the big export demand, and to the renewed activities of Canadian consumers, who allowed their shelves to empty when general business was so bad a year ago.

Personal

William J. C. White, head of the firm of R. C. White & Co., engine and boiler makers, Montreal, died in that city on March 24.

George P. Breckon, head of the firm of G. P. Breckon & Co., sheet metal workers, Toronto, Ont., died suddenly at his plant on March 30.

George Smith, town engineer of Lindsay, Ont., died suddenly in Toronto on March 31, while on a visit to a friend. The deceased was 60 years of age.

Alonzo B. See, president of the A. B. See Electric Elevator Co., Montreal and New York, has been elected vice-president of the Machinery Club of the City of New York, to succeed the late John A. Hill, publisher of the American Machinist.

Donald Fraser, sen., one of New Brunswick's most prominent lumbermen, died at Fredericton on April 1. He built up what is believed to be now the largest lumbering and milling business in eastern Canada. He was a native of Scotland and was seventy-four years old.

N. Bruce McKelvie, of the firm of Hayden & Stone, Boston and New York, has been appointed a director of the Nova Scotia Steel & Coal Co., Halifax, N.S. Mr. McKelvie is a native of Prince Edward Island and was at one time on the Bank of Nova Scotia staff. This appointment completes the board of directors.

A. E. Wright, of the Dominion Steel Foundries, Hamilton, Ont., has been promoted to the position of secretary-treasurer, and **Fred W. Sherman** will assume the duties of purchasing agent. **Mr. Hammon,** who was formerly secretary treasurer has severed his connection with the company, and has taken up his residence in California.

Railways—Bridges

Quebec, Que.—A movement is on foot in the Saguenay district, notably at Bay St. Paul, to get the Federal authorities to extend the lines of the Canadian Transcontinental out from Quebec to St. Catharine's Bay, Saguenay, which is claimed as an excellent site for winter navigation up the river.

Building Notes

Toronto, Ont.—A company, headed by H. H. Williams, has taken out a charter for $1,000,000, and as soon as plans are perfected, propose to erect a large theatre at the corner of College and Teraulay Streets. It will have a very large stage and a seating capacity of from 4,000 to 5,000. No definite date has been set for the beginning of building operations.

Marine

North Vancouver, B.C.—The Amalgamated Dry Dock & Engineering Co., if it secures certain concessions, will erect a dry dock and shipbuilding plant at an estimated cost of five and a half million dollars.

Refrigeration

St. Thomas, Ont. — The St. Thomas Pure Milk Co., which has recently been incorporated, will install a plant for pasteurizing milk.

Toronto, Ont.—It is reported that the Delaware and Lackawanna Railroad have purchased a property here for a terminal to be used jointly with the C.N.R.

Wood-Working

Elmira, Ont. — Fire starting in the boiler room of the Bauman & Letson planing mills, completely destroyed the

Page 56 contains something that will interest you. Turn to it.

buildings on March 28, entailing a loss of from $15,000 to $20,000. The property was partly covered by insurance.

Catalogues

Blowing Engines made by the Nesta Machine Co., Pittsburgh, Pa., are dealt with in a catalogue recently issued. Some large installations are illustrated accompanied by a brief description.

Tool Steel.—The Vanadium-Alloys Steel Co. of Pittsburgh, Pa., has just issued two folders descriptive of their "Vasco Choice" and "Vasco Non Shrinkable" grades of tool, steel. These folders will be sent free upon request.

Book Review

Sampling and Analyzing Flue Gases is the title of bulletin No. 97, issued by the Bureau of Mines, Department of Interior, Washington, D.C. The bulletin by Henry Kreisinger, engineer, and F. K. Ovitz, assistant chemist, presents for the benefit of those in charge of boiler plants and all other persons interested detailed information on methods of sampling and analyzing flue gases, and on the utilization of the analyses in promoting boiler-room economy. This bulletin is intended to be a companion to Technical Paper 80, "Hand Firing Soft Coal Under Power-Plant Boilers," and is written in plain and non-technical language, as far as possible, so that it may be readily understood by persons who have not had the advantage of a technical education.

The material presented is arranged in two parts. The first part contains the description of the apparatus and the methods used in sampling and analyzing flue gases. The second part gives experimental results obtained with the different methods of sampling and collecting flue gas that are recommended in the first part of the report. Only simple apparatus and methods are considered, as they are accurate enough to show the large heat losses due to the use of too much air, and are also accurate enough to indicate any incomplete combustion losses of economic importance. Those who wish to obtain information on the more accurate methods of analysis of gases are referred to Bureau of Mines Bulletin 12, "Apparatus and Methods for the Sampling and Analysis of Furnace Gases," and Technical Paper 31, "Apparatus for the Exact Analysis of Flue Gas," which may be obtained from the Superintendent of Documents Government Printing Office, Washington, D. C., at a cost of five cents each. Bulletin 97 may be obtained by addressing the Director of the Bureau of Mines, Washington, D.C.

Classified Advertising Section

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Five cents each insertion when box number is required. Each figure counts as one word. Display rates on application.

FOR SALE

FOR SALE—NO. 2 UNIVERSAL MILLING machine. J. A. Harvey, 16 Pearl St., Toronto.

SIX-FOOT METAL PLANER FOR SALE—practically new. Apply A. Graham Boyd, 100 Front St. E., Toronto. (14)

TWO FOX TURRET LATHES FOR SALE—splendid condition. Ideal Foundry, 910 Gerrard St. East, Toronto. Phone Gerrard 1055. (15)

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

FORD-SMITH NO. 2 PLAIN MILLING MAchine: new: in perfect condition: ready for immediate shipment. McGregor & McIntyre, Ltd., 1139 Shaw St., Toronto. (16)

FOR SALE—FIFTEEN HUNDRED GALLON Duplex Steam Pump, used sixty days. Size twenty x twelve x sixteen stroke. Apply Fraser & Chalmers of Canada, Limited, Montreal. (12)

FOR SALE—GARAGE IN GOOD WHEAT district. Snap for a good, practical man. About forty cars in vicinity. Will sell cheap if taken at once. Address Box 74, Hanley, Sask. (13)

FOR SALE—ELECTRIC GENERATOR TO run 80 lamps, 110 volts, 300 r.p.m., including switchboard and indicator; in good condition. Richards-Wilcox Canadian Company, London. Ont.

FOR SALE OR TO EXCHANGE FOR A smaller tool—Bertram gap lathe, 16-ft. bed, swing 40 inches in gap, two face plates, one 4-jaw chuck, one steady rest, one turret head, and countershaft. All in first-class condition. Offered at a big reduction. Shipment could be made in ten days. Box 182, Canadian Machinery.

FOR SALE — COMPLETE LUMBER AND lath mill machinery, daily capacity seventy-five thousand feet, consisting of gang, single and double bandsaws, engine, boilers, etc. Fully equipped blacksmith and machine shops. Silsby fire engine, 2 streams of 2½ inch; good order. Log loader, capacity fifty thousand feet, ten hours; almost new. Exceptional manufacturing site bargains. Address The Rathbun Company, Deseronto, Ont. (18)

ELECTRODES — THE PROPRIETORS OF letters patent No. 127080, relating to "Process of manufacturing iron for use in alkaline accumulators," and No. 127081, relating to "Active masses for positive electrodes of electric elements, etc.," desire to dispose of the patents or to grant licenses to interested parties at reasonable terms, with a view to the adequate working of the patents in Canada. Inquiries to be addressed to the actual proprietors, Svenska Ackumulator Aktiebolaget Jungner, Stockholm, Sweden. (13)

MACHINES AND TOOLS FOR SALE

One No. 3 Le Blond Miller, with all modern attachments, complete.

One handy lathe, 10 x 18 in.

One under draft latest improved Buffalo forge. (These tools are practically as good as new.)

Also a number of other lathes and drill presses.

Apply MEYER BROS.,
110 Adelaide Street East, Toronto
(17)

FOR SALE—1 CLEVELAND ACME MAchine Co.'s 6" Cap. Single Head, Tapping Machine—back-geared, automatic feed, cone step pulleys and countershaft with two extra chucks. Particulars from Taylor-Forbes Company, Limited, Guelph, Ont. (13)

FOR SALE, AT A SACRIFICE—SAW MILL outfit, A1 condition; 50 H.P. stationary boiler, 45 H.P. "Leonard" engine, "Green" carriage, Simonds saw, edger, planer, lathmill, etc. Easy terms. Write quick. R. Parker & Sons, Uno Park, Ont. (12)

FOR SALE—2-PHASE INDUCTION MOTORS, 1 only WESTINGHOUSE, Type C, 50 H.P.; 1 only WESTINGHOUSE, Type CCL, 50 H.P.; 1 only CANADIAN GENERAL, type 10, 20 H.P. In excellent condition. Prices attractive. Full particulars on application. Cummer-Dowswell, Limited, Hamilton, Ont.

FOR SALE—PLANING MILL AND FACTory, doing good business. Terms $2,000.00 cash. Balance to suit buyer. Address O. Ribble, Bronte, Ont. (13)

AUTOMOBILE BUSINESS AND NEW Garage for sale. Overland agency; lots of repairing; also Overland roadster, new tires, $300.00; 10 light D.C. generator, $25.00; K.W. magneto (new), $15.00. W. E. Hawes, Otterville, Ont. (13)

AGENTS WANTED

BRITISH HOUSE MAKING SYRINGES AND spraying machines for every possible use, need Canadian agents. The line is the most complete in the world and includes knapsack and ordinary spraying machines for fruit growers, limewashing machines for farms, factories, etc. Disinfecting machines for all purposes. Anything in the way of spraying and washing machines made to suit the market. Agents must be aggressive and ready to work the line thoroughly. Write: Spraying Machines, c|o Canadian Machinery, 143 University Avenue, Toronto.

SITUATIONS VACANT

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month. Box 184, Canadian Machinery.

WANTED — MACHINISTS AND FLOOR hands on heavy and miscellaneous medium work; steady employment, modern shop, good wages. Apply, stating age and experience, P.O. Box 6, Walkerville, Ontario. (6)

WANTED

Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN LAMP FACTORY
ST. CATHARINES, ONTARIO

WANTED

WANTED TO RENT — SMALL MACHINE shop, two or three small lathes, miller, drill, motor, furnace, usual small tools. Full particulars and terms. Box 179, Canadian Machinery. (13)

WANTED — TWO FIRST-CLASS STEEL moulders. Apply Nova Scotia Steel & Coal Company, Limited, Sydney Mines, N.S. (15)

WANTED—OUTSIDE MACHINIST TO ACT as mechanical foreman on construction work. Apply to A. B., Canadian Machinery. (15)

WANTED — YOUNG CHEMIST WHO HAS had some experience in analysis of iron, steel and other steel plant products. Apply to X. Y., Canadian Machinery. (15)

SITUATIONS WANTED

MECHANICAL SUPERINTENDENT, EFFICIency engineer and master mechanic having twenty years' experience in all lines of general machine, blacksmith, carpenter and pattern shop practice, foundry work, power plant, refrigerating and electrical engineering, is open for engagement. Box 177, Canadian Machinery. (11)

CHIEF ENGINEER — 26 YEARS' EXPERIence. Factory and Central Station, Alternating and Direct Current, Gas or Steam Engines. efficiency guaranteed, own instruments, best of references. Box 181, Canadian Machinery. (12)

AS MAINTENANCE ENGINEER OF FACTory, power or lighting plant, where economy is a factor, wide experience, best of references. Box 180, Canadian Machinery. (12)

The Installation and Maintenance of Transmission Belts

Staff Article

No part of plant equipment repays so highly the labor expended on it as does power transmission belting. The manner in which it continues to discharge its duty in spite of neglect and abuse indicates to some slight extent the degree of efficiency and economy which would be obtained with proper care and attention. Belting suffers silently and never drops till it is dead; with care and attention its life would be long and its service more satisfactory.

TO obtain, and maintain, the highest possible efficiency in power transmission, has been, and still is, an unsolved problem. Many substitutes for leather belt transmission have been devised, and have met with varying degrees of success, but nothing has as yet been produced, that for general, allround purposes can oust leather belting from the leading position. If the question of belt-driving is given equal consideration with many other forms of transmission, it will demonstrate beyond question its greater efficiency and economy. Wherever practicable the care of all belting should be under the supervision of one man. When this work is left to each individual machine operator the efficiency of belting becomes a minus factor. With the problem in the hands of one capable man there is the assurance that experience will evolve ways and means to obtain the maximum efficiency from the belts under his charge.

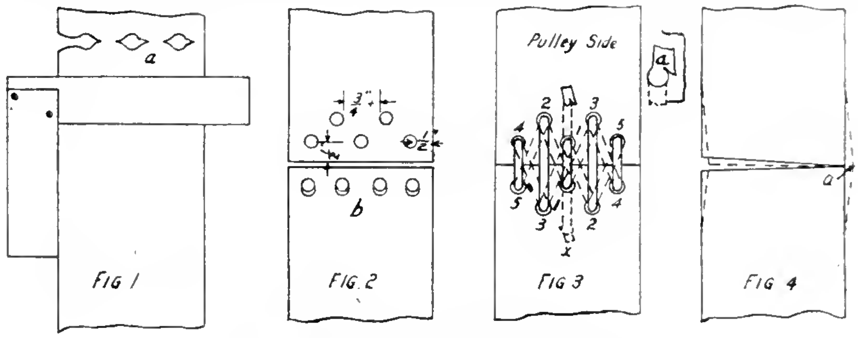
In the following article several details in connection with the use and abuse of belts and pulleys are set forth which may be profitable to those having the care and handling of belts and accessories.

Trimming and Punching Holes

When trimming a belt preparatory to lacing, always have the ends cut perfectly square; the proper joining of the ends of a belt is a question of paramount importance, and satisfactory operation is largely dependent upon the manner in which this work is performed. The correct way is to mark off the belt by means of a try-square, as shown in Fig. 1. By this method there is assurance of an even joint which will be free from any irregularity as it passes over the pulleys.

If proper attention is overlooked in this connection there is a possibility of producing a point similar to that shown by the dotted lines in Fig. 4. When this bulge (a) reaches the pulley, the tendency is to run off—or in the case of cone pulleys—to climb to the next higher step.

One of the most important factors in connection with efficient belt service is the proper use of the belt punch. By closely observing an old and worn joint it will be noticed that the holes have a shape similar to that shown at (a) Fig. 1. This shows that the tension of the lace causes rupture, through the holes, "across" the belt; very seldom will the lace pull out through the end of the belt. Therefore, it is advisable to provide plenty of space between the holes; good practice under general conditions would be an allowance of at least $\frac{1}{2}$ inch between the end and the holes, and a similar amount on each edge, with from $\frac{3}{4}$ inch to 1 inch between the holes; if it is necessary for a double row of holes the second row should be about $\frac{3}{4}$ inch back of the first row.



TRIMMING AND LACING THE BELT.

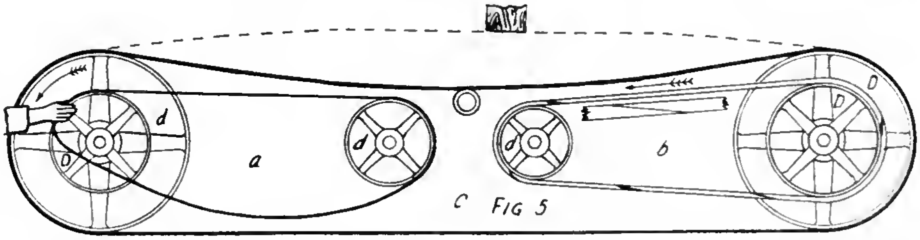
In the advent of an extra heavy lace being used it sometimes becomes necessary to enlarge the holes. From the above it is evident that the enlargement should extend lengthwise of the belt, as shown at (b), Fig. 2. Never use a punch larger than absolutely necessary, as every additional bit of stock removed only weakens the belt. The selection of a suitable lace should be given careful consideration. A thin strong lace is to be preferred to a heavier one of the same strength, as in the majority of cases it is the belt that breaks through the holes before the lace is broken.

Lacing the Belt

Numerous methods are used for the joining of transmission belts, but the one generally adopted, and the most satisfactory, is that of leather lacings. Many rules have been formulated for the lacing of belts; in fact, is would appear that every other mechanic has a different process. However, the course usually followed is shown in Fig. 3.

It might be stated here that the generally accepted rule is to run the hair or smooth side of the belt on the pulley. This, however, is an open question, as experts seem to differ on the subject.

When lacing a belt, it is always advisable to keep the lace on the inside parallel with the travel of the belt. To attain this proceed as follows: Insert the lace as shown in the two centre holes 1 and 1, keeping the straight portion on the side that is intended to run on the pulleys. With the ends of the lace of equal length, proceed as indicated in Fig. 3, working from each side simultaneously, 1-2-3-4-5-4-5-2-3-1-x. The hole x should be a tight fit for the lace, and when the lace is finally drawn through x, it should be notched and cut, as shown at (a). This, when properly done, acts as a good reliable lock for the lace ends. The use of knots is often resorted to, but is gradually being discontinued. When the joint is completed it may be slightly pounded with a wooden mallet, to flatten the lace before placing the belt on the pulleys.



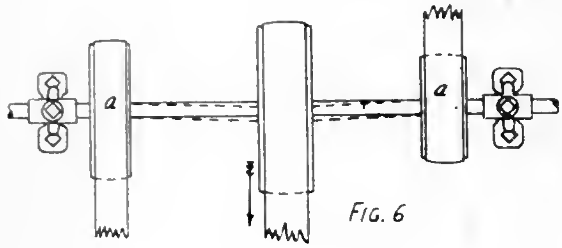
DIRECTION OF BELT TRAVEL AND PULL. PLACING BELTS ON THE PULLEYS.

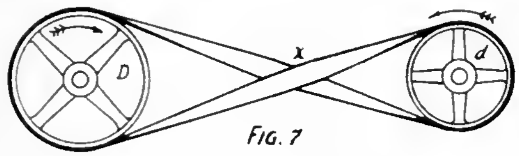
Direction of Travel and Pull

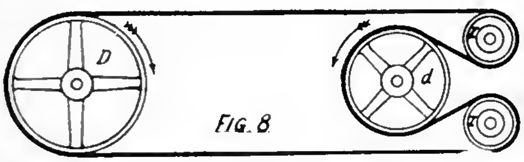
As leather belts are made of short

sections, joined together with a long wedge-shaped cemented splice, it is sometimes deemed wise to place the belt on the pulleys, so that this splice will lie as shown at (b). Fig. 5.

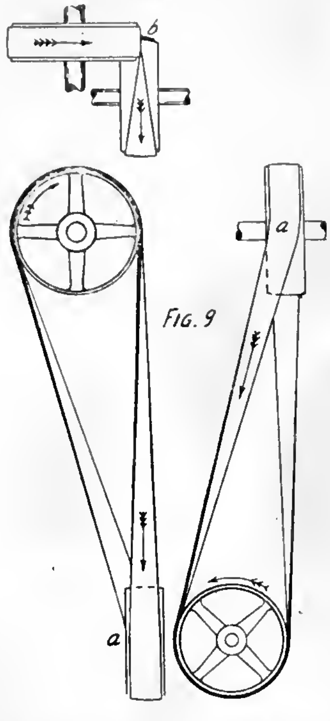
When dampness or other causes affect this joint so that the cement begins to slacken up, the thin end of the joint shows a tendency to curl, and by placing the belt as shown this trouble can be largely prevented, the action of the belt travel helping to keep the thin edge rolled down.



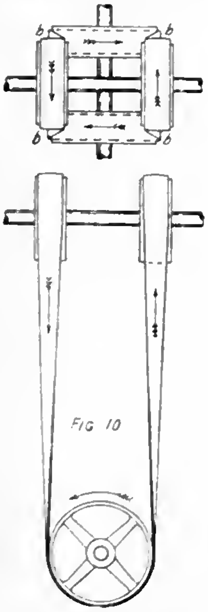




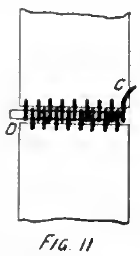
SHAFT SPRING, CROSSED BELT, AND CHANGE OF ROTATION DIAGRAM.

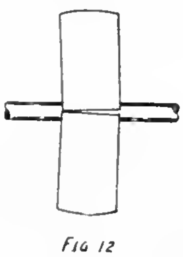


QUARTER TURN BELT ARRANGEMENT, TWO PULLEYS.



QUARTER TURN BELT ARRANGEMENT, FOUR PULLEYS.





METAL JOINTS AND WOODEN PULLEY TROUBLE.

When putting on a belt always place it over the dead—or, in other words, the driven pulley first; then from the back of the driving pulley D, the belt can be drawn on with the hand, as shown at (a) Fig. 5. Under no conditions should a person stand between the driving and the driven pulleys when putting on a belt. Some men advocate the use of a stick for this purpose, and in the hands of an experienced person it may have its advantages, but unless great care is exercised in handling the same, the risk of injury from the stick being caught will be as great, if not greater, than the use of the hand method. Where the belt is exceedingly tight, or long and heavy, it is best to shut off the power and perform the operation at very slow speed.

To derive a maximum amount of power from a belt drive the pull should come upon the lower portion of the belt, as by so doing the slack will sag on the upper half, giving increased belt contact on the pulleys. It is also advisable that wherever possible the direction of pull should be evenly distributed along a line of shafting. From this it is clear that with a main line operating numerous counter shafts on each side (with open belts) the slack of the belts on one side will be on the top and those on the opposite side will show sag on the lower portion.

Belts Too Slack or Too Tight

There are those who advocate a very slack belt with plenty of belt dressing, but under ordinary conditions it is not profitable to run a belt either too slack or too tight. A very slack belt will have a tendency to slip or flop when sudden loads are applied, and an extremely tight belt will cause undue strain upon the shafts and bearings. This is emphasized when the pulley is midway between supports, as shown in Fig. 6; the dotted line showing an exaggerated condition under such circumstances.

Driving pulleys for heavy duty, or when subjected to sudden loads, should always be placed as close to a hanger as possible, as shown at (a) Fig. 6.

When the slack of a belt is subjected to continual flop or oscillation, care should be taken that no pipes, beams or other obstructions come in contact with the belt, as the constant rubbing, or striking will in time destroy the belt and cut the lacings.

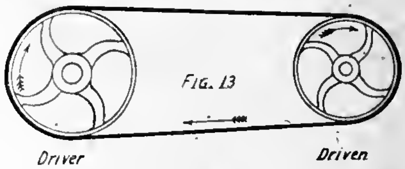
Changing Direction of Rotation of Parallel Shafts

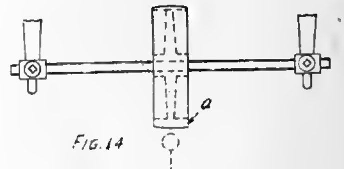
Where it is necessary to change the direction of rotation of two parallel shafts, crossed belts are used, as shown in Fig. 7. It is advisable that the rubbing faces at (x) should be the inside or pulley side of the belt, as the laces on this side are smoother and not so liable to wear as the outer parts of the lace. When the load is applied, crossed belts will often show a tendency to run off the pulley: this can sometimes be remedied by twisting the belt in the opposite direction.

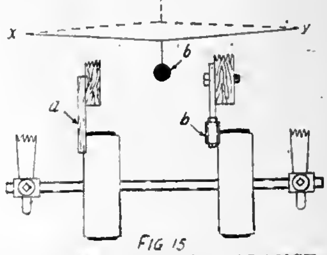
A change of rotation may be obtained by the method shown in Fig. 8 by the use of two idlers, I-I. This, however, necessitates the belt running on both sides.

Quarter-Turn Drive

Where it is desired to drive a shaft at right angles to another shaft various methods have been adopted; but the one generally used is that shown in Fig. 9. The principal objection to this drive is the constant fibre strain set up in the belt, due to the angle formed as it leaves the pulley at the points (a, a), also the fact that the rotation is only possible in



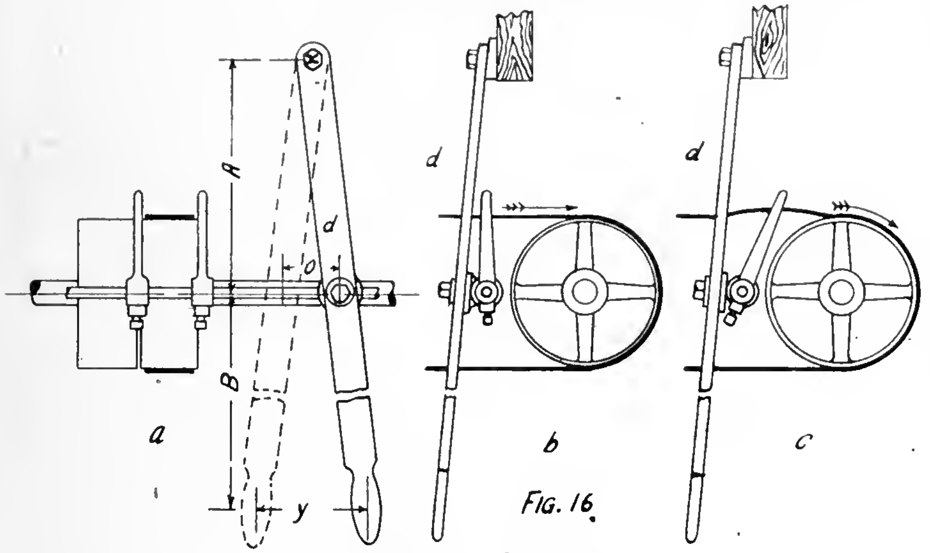




CURVED ARM PULLEYS, BALANCE OF PULLEYS AND BELT GUIDES.

one direction (that indicated by the arrows). The chief consideration in laying out a quarter twist drive is that the points (a, a) where the belt leaves the pulleys should lie in the same vertical line, as shown at (b). This rule also applies to all angular horizontal drives.

Another method of quarter-turn drive, involving the application of four pulleys, is shown in Fig. 10. The same principle applies in this case as that shown in Fig. 9, viz., the point where the belt leaves the pulleys should be in the same vertical line. It will, however, be noticed that in this figure the belt can be run in either direction. It will also be observed that the two pulleys on the one shaft are travelling in opposite directions, which indicates that one will be a driving pulley and the other will be an idler or loose pulley, which is kept in position with collars (not shown) secured to the shaft. The speed of the loose pulley, in relation to the shaft will therefore, be twice that of the driving pulley, when pulleys are of the same diameter.



BELT SHIFTER TROUBLES.

Metal Joints

During the past few years many forms of metal joints and wire lacing have been designed and adopted; but while they may be highly recommended for certain purposes, they should not be used where necessity arises to shift a belt by hand. Experience has shown that joints of this description, after becoming somewhat worn will allow the metal or frayed wire, and often the raw hide pin, to protrude as shown at c and d, Fig. 11: this condition sometimes proving injurious to the machine operator.

A common cause of belt trouble is that shown in Fig. 12, where a wooden pulley hangs crooked on the shaft, owing to one side being tightened up more than the other. This fault should be remedied as early as possible.

Belt Guides

Where belts acquire a habit of continually slipping off on one side of a pulley, when taking up a load, it is a common practice to put up a temporary guide, in the shape of a stick nailed to a joist, as shown at (a) Fig. 15. This in many instances proves to be a permanent fixture, which in time will materially affect the life of the belt as the constant friction will ultimately fray or curl the edge. If it seems necessary to construct a guide for this purpose the method shown at (b) is suggested. This is a roller running on a rod, which is secured to the beam above. By this means the friction is considerably reduced by the rolling action; and the effect on the belt is less harmful.

While contrivances of this nature reduce the trouble of belts slipping off to a large extent, the general adoption of such methods should not be encouraged, as the advantages derived are not sufficient to counteract the loss sustained through belt depreciation.

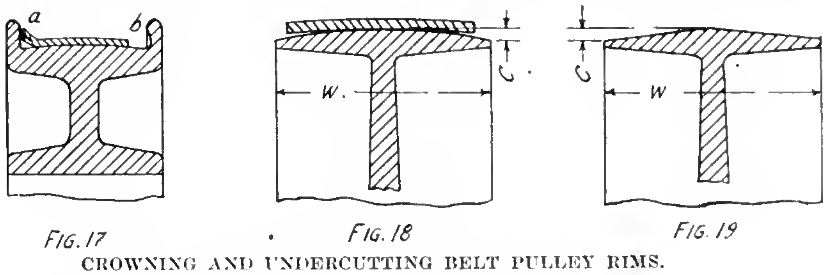


FIG. 17 FIG. 18 FIG. 19
CROWNING AND UNDERCUTTING BELT PULLEY RIMS.

The source of the trouble should be located as early as possible, and steps taken to eliminate it. This will likely be traced to shafts out of line, too great or insufficient crown, pulleys out of line, faulty belts, etc., or a combination of one or more of the above.

Balancing of Pulleys

When shafting is running at high speed, more attention is required in the balancing of pulleys. This, at first sight, seems a question of minor importance, but if the speed is excessive and the pulley of fairly large diameter, any irregularity in the mass of the metal will have a corresponding effect upon the shafts and bearings. The centrifugal force of the revolving pulley will cause the heavy section (a) Fig. 14, to swing farther from the centre of motion. This action can be more clearly illustrated by referring to the lower sketch, where the unbalanced weight is represented by a ball on a cord. By revolving the cord x-y at high speed, the centrifugal force set up will cause the cord x-y to be distorted from a straight line; the position taken up being represented by the dotted line. This lack of balance is often the cause of "sprung" shafts. It is therefore necessary, that high speed pulleys be properly balanced before being placed on the shaft. The most frequent method of balancing fly-wheels or pulleys is with the horizontal straight edge. This is very satisfactory where the speed is below the average; but when the speed is great, this method may not be reliable. For instance, a pulley may be found to be out of balance from excessive metal at the lower or hub end of one of the arms; metal is applied by the welding process to the rim end of the opposite arm, sufficient to show perfect balance on the straight edges. When the pulley is placed on the revolving shaft the speed will cause the pulley to be out of balance, but in the opposite direction to the original test. This is owing to the added metal being placed at a greater distance from the centre of motion.

When pulleys with curved arms are being used it is always advisable to have the curve face in the direction of the pull as shown in Fig. 13, so that the metal in the arms will be under compression. This method increases the limit of power which the pulley can transmit.

Belt Shifter Trouble

Trouble is often experienced from a belt creeping from the loose to the tight pulley of the machine counter-shaft. The source of this annoyance is usually found in the belt shifting apparatus. In Fig. 16 is shown a partial front and two side views of a belt shifting arrangement. If the shifting lever (a) travels much past the centre line of

action x-y, the force of gravity will tend to bring the stick back to a vertical position, especially if the parts move freely.

To overcome this trouble the connections should be sufficiently tightened to avoid free movement, and where possible the distances A and B should be so proportioned that the movement (y) is no greater than what is necessary.

When placing the forks on the shift rod they should be secured in the position shown in (b) Fig. 16, at right angle to the travel of the belt. If secured at an angle, as shown at (c), the force exerted to move the belt will cause the edges of the belt to curl up as they come in contact with the inclined fork.

Crowning and Undercutting

The trouble met with in cases such as that of Fig. 15, may be also experienced with cone or flanged pulleys.

In Fig. 17 is shown a small flanged pulley with the belt climbing the face of the flange (a). This may be due to the causes previously mentioned or from an accumulation of dirt or belt dressing on the inner face of the flange. These flanges, and also the faces of cone pulleys should be undercut as shown at (b). When this is done the belt is only in contact at the edges where it enters and leaves the pulley.

Where belts are constantly run in the one position, it is advisable to crown the face of the pulley, as a belt under normal conditions will always run to the high point, and if this point is in the middle of the face the belt will retain a centre position on the pulley. However, there is a limit to the advantages derived from this process, for, if the convexity is too great the lack of flexibility in the belt will materially affect the contact on the face of the pulley, as shown in Fig. 18. The general rule for the crowning of pulleys is about ¼ inch to the foot of width, or $C = \frac{W}{48}$. This crown should have the shape of the section of a sphere as in Fig. 18, but in some cases two frustums of cones are formed as shown in Fig. 19.

It might be said in conclusion, that too much attention cannot be given to the proper care of belts and pulleys, as the efficient operation is often seriously affected by careless and inexperienced handling of this part of machine shop equipment.

CONCRETE FLOORS FOR WORKSHOPS

CONCRETE makes a cheap floor for a workshop, but in many cases its efficiency is often spoiled through its getting cracked after some little time, and eventually more or less broken up. As the cause of this is not generally understood, the following remarks by B. Davis, H.M. Inspector of Factories for the Kent district, may be of interest. He remarks that in addition to the obvious reasons that builders often use too much sand in proportion to the cement, and have an insufficient thickness on bad foundations, there are others due to ignorance when the intention is good. Mixtures of sand and cement expand when they are wet, and contract as they dry, and within limits the greater the proportion of cement the greater the expansion and contraction.

A common practice is to put down a first layer of material with a small proportion of cement, to let this dry, and then put on top of it a thin layer with a large proportion of cement. This top part thus remains a separate layer instead of bonding with the lower part, as it would have done had it been put on at once on the still unset lower portion, while, being richer in cement, it expands and contracts more than the lower part, with the result that it may be rapidly broken up. For large surfaces, however good the workmanship and material, the expansion and contraction are almost certain to produce cracking unless the job is divided up vertically into sections with thin strips of wood between them.

PRESERVATION OF IRON PATTERNS

A METHOD of preserving iron patterns from rust and corrosion is first to subject them to an air blast to remove dirt and dust, and then to immerse them in a pickle composed of 5 gallons of water and 1 pint of sulphuric acid. This is used hot, and the patterns are allowed to remain in it for 5 min. The patterns are then rinsed in water and dipped into a hot potash solution made by dissolving 1 lb. of potash in 1 gallon of water, thus neutralizing the acid left in the pores of the iron. The patterns are allowed to remain in the solution for about 5 min., and are then scoured with a stiff brush to remove the rust and again dipped into the sulphuric acid for a minute or so. They are then rinsed in cold water and not allowed to dry, afterwards being immersed in a weak cyanide of potassium solution made by dissolving 2 oz. of the cyanide in 1 gallon of water. Copper plating takes place in the regular cyanide copper-plating solution used by all electroplaters. The solution is used hot, and the deposit need not be thick, the time necessary being usually from 5 to 10 mins.

The next step is to rinse and dry the patterns, after which they are warmed and paraffin wax rubbed over the surface as a thin coating. When cool, the surface is brushed with a bristle brush in order to smooth down and even up the paraffin coating. They are then ready for use. The paraffin protects the copper from corrosion and allows the pattern to leave the sand easily.

CANADIAN RAILROAD DE . MENT

THE annual railway statistics blue book, tabled in Parliament at Ottawa, on April 4, shows that, despite the war, an addition of 4,787 miles was made to the operating mileage of Canadian roads during the year ended June 30 last. The greatest increase was in the Provinces of Ontario and British Columbia.

Ontaria has still a railway mileage more than double that of any other Province, with 10,708 miles in operation. Canadian lines in the United States have a total mileage of 3988.

An increase of $66,990,127 in railway capitalization for 1915 brought the total up to $1,875,810,888. Dividends on stocks amounted to $32,341,337, as compared with $30,434,601 for 1914. Government-owned and operated lines which are not capitalized showed a cost of $293,542,201.

Cash subsidies amounted to $5,059,284, of which the Dominion contributed $4,644,664 and the Provinces $414,020. The whole account for aid in cash, constructed lines, loans, etc., stands at $238,831,924. Land grants have totalled 43,929,312 acres, and guarantees have been authorized amounting to $409,869,165.

There were 46,322,035 passengers carried in 1915, and 87,204,838 tons of freight; this was a decrease of 380,245 passengers and 14,189,151 tons of freight.

Gross earnings fell from $243,083,539 in 1914 to $199,843,072 in 1915. Both passenger and freight decreased, but operating expenses also decreased and the aggregate was equal to 73.9 per cent. of the gross earnings.

Although there were increases of motive power and of cars for passenger service, there was an actual decrease of 2,500 in the number of cars available for freight service. The railways took advantage of the conditions to take out of operation a considerable number of old and much-worn cars. The number of employees was reduced from 159,148 to 124,142. Salaries also declined by more than twenty millions.

Railway operations resulted in 384 persons being killed and 3,161 injured. Only seventeen of the killed were passengers.

Copper Production in B.C.—The Hon. Lorne Campbell, Minister of Mines for British Columbia has stated that 100,000,000 pounds of copper valued at $20,000,000 would be produced at the Granby Britannia and other mines on the coast every year in the near future.

PRODUCTION METHODS AND DEVICES

GAUGES IN MODERN MANUFACTURING PRACTICE—II.

By F. H. Mayoh.

WHILE those referred to above are termed standard types, and are such, inasmuch as they can be bought from most any dealer, there are others which are equally as important in specialized manufacturing practice. Some of these

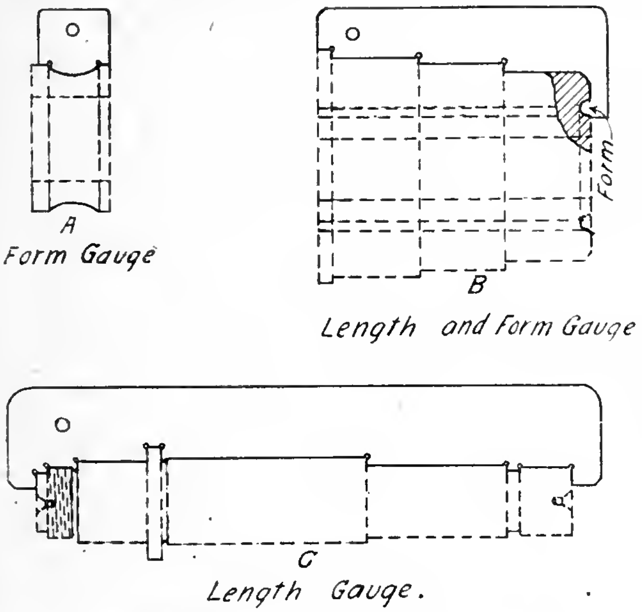

FIG. 5. SIMPLE TYPES OF SPECIAL GAUGES.

are the length and form gauges, Fig. 5, made in various forms and lengths for gauging work similar to that shown being gauged at A, B and C.

Length Gauges

Another style of gauge, which is also a length gauge, is shown in Fig. 6, and consists of a bar A, a head B, and a scratcher C. In this tool the scratcher C is held on the end of the bar by means of the screw D, while the head B slides on the bar and is adjustable to different lengths. It is used for scratching lines

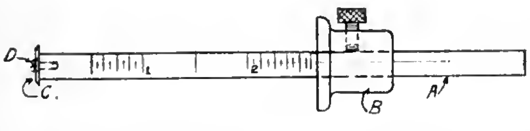

FIG. 6. ADJUSTABLE SCRATCH GAUGE FOR MARKING OFF.

on sheet metal or other parts similar to those shown at A and B, Fig. 7, and numerous other purposes. Again referring to Fig. 7, the dot and dash lines at A were drawn by this scratch gauge, and at B the scratcher is shown in position for drawing a line.

Gauging the relation of a hole to the end of the piece is quite often done by means of a plug and bar gauge, Fig. 8, where the plug A fits into the hole and distance from the end is measured by the plug B which has two diameters machined on it to correspond to the limits of length allowed the small diameter to go past the end and the large diameter not to go. Similar gauges to these are often used for gauging the relative distance between two or more holes.

Valve Seat Gauge

To measure a valve seat, a gauge similar to Fig. 9, is often used which slips over the shank on the valve and gauges the seat by means of the step A, which indicates whether the bevel is the correct length by requiring that the seat of the valve B come between the step A, when the seat has been machined correct.

Taper Gauges

Three taper gauges are shown by Fig. 10, consisting of a plug taper gauge which shows both the amount and diameter of the taper the first by placing a chalk line or Prussian blue along the plug and wringing it into the taper hole when by removing the same if the hole has the right taper all the chalk will be removed while if not correct the chalk will be removed in spots. Secondly the ring B is for measuring the outside taper on a piece in the same man-

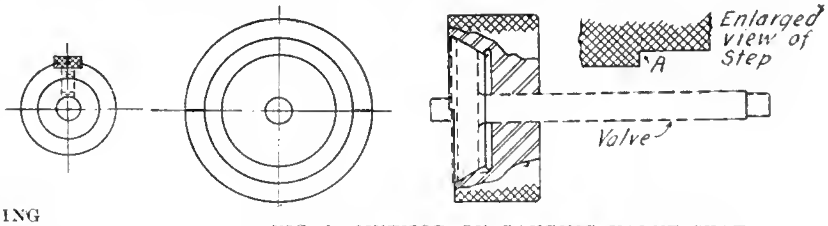

FIG. 9. METHOD OF GAUGING VALVE SEAT.

ner as when using the plug, while lines on the plug (a) and the step on the ring (b) indicate whether the diameter is within the required limits.

The third gauge C is a transfer gauge meaning that a taper plug is placed between the jaws (d^1) and the jaws set to conform to the taper of the plug. When

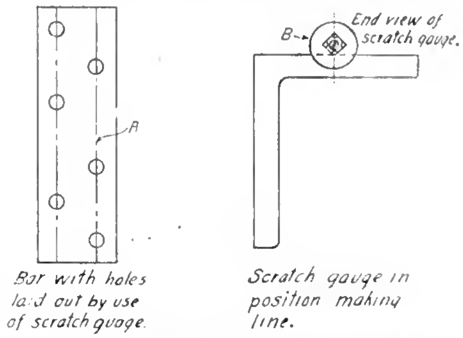

FIG. 7. METHOD OF USING GAUGE.

by taking the plug out and trying the pieces being machined between the jaws it can be seen whether the taper is cor-

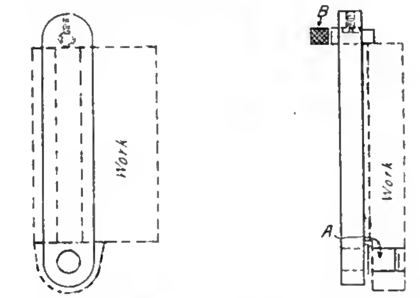

FIG. 8. GAUGE FOR TESTING RELATION OF HOLE TO END OF WORK.

rect or not. This gauge is not limited to one taper but can be set for various tapers.

Button Gauges

The use of buttons for gauging is another important consideration and two illustrations showing their application are given in Fig. 11, where the upper one is shown measuring an angular dimension from a pin. In this case the hole A is first located, bored, and a pin placed in this hole, following which the holes B and C are bored as follows: The centres for these holes are first located approximately by measuring with a scale in the usual manner and drilling a small hole for a screw. The next step is to place a bushing or button in position, when, by measuring from the pin

to the buttons and also between the buttons as indicated. D, E and F are obtained, these distances being equal to the centre distances minus the radius of the pin and buttons. The buttons can be clamped by the screws in the correct locations when by proceeding as shown in the lower view the holes may be bored. The procedure for boring a hole accurately by the button method is to set the work up true in a lathe by means of a test indicator (X) which multiplies any errors, the manner of using being obvious from the illustration.

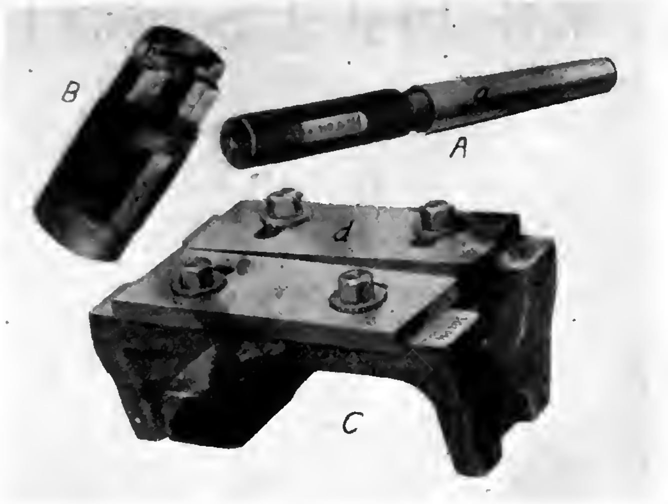

FIG. 10. A TAPER RING GAUGE.

Another button method of measuring is known as the Sine Bar Method, and this is used for measuring tapers, the idea being that by measuring the differences between the position of the pins at each end of the bar A when set in a holder B, Fig. 12, the taper can be computed, the work to be measured being tested between the two surfaces in the usual manner of using a protractor.

POWER ABSORBED BY SHAFTING

IN the course of a paper on "Modernization of Power Plant in Factories," read before the Junior Institution of Engineers, W. A. Tookey said that during recent years he has had a number of opportunities of determining the amount of power absorbed by shafting and belts in factories, and it will be seen from the list given in the accompanying table, taken indiscriminately from his records, that in many instances the proportion of power thus accounted for of the normal output from the engines concerned is extremely high.

Power Absorbed by Shafting in Small Factories

This is not remarkable, having regard to the conditions which obtain in the majority of factories when the shafting is erected as cheaply as possible, of as light a character as will just do the work, and supported on bearings at wide intervals, which in their turn are often bolted to insubstantial structures. Pulleys are frequently as small as parsimony dictates, so that with heavily-stressed belts anything like ideal efficiency cannot be approached. It will be evident that the dust rising from grinding and woodworking plants greatly increases the proportionate "shafting loads."

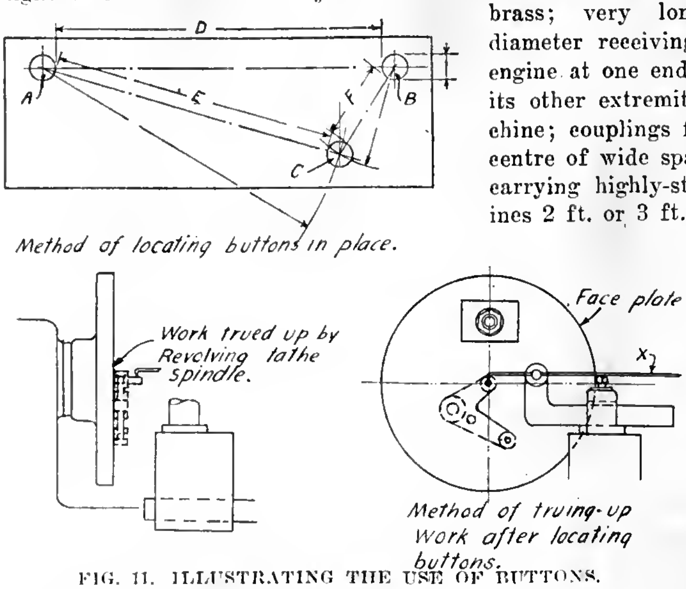

FIG. 11. ILLUSTRATING THE USE OF BUTTONS.

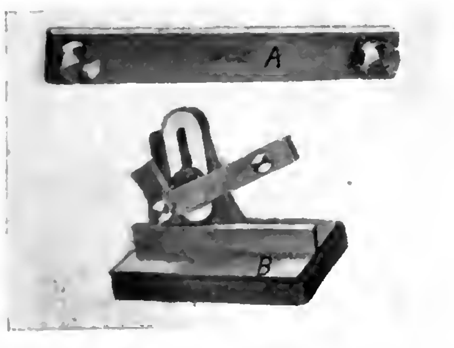

FIG. 12. METHOD OF MEASURING TAPERS WITH SINE BAR. B—DIFFERENCE IN HEIGHT OF PINS FROM BASE DETERMINES TAPERS.

There is probably no need to remind engineers of the circumstances under which shafting and belts operate, says Vulcan. From the time that the shop starts work in the morning until the engine is shut down at night there is no opportunity of doing much to the shafting in the way of adjustment, however badly it may require it, while it is only in cases of breakdown, actual or imminent, that any attention is, in fact, given to it.

Mr. Tookey said he had seen bearings that had been worn through the bottom brass; very long shafts of small diameter receiving the power from an engine at one end, and giving power at its other extremity to some heavy machine; couplings fitted to shafts in the centre of wide spans; and large pulleys carrying highly-stressed belts to machines 2 ft. or 3 ft., and sometimes more, from the nearest bearing. He had been able to count the speed of rotation of a shaft by noting the periodicity of its dog-leggedness, and had seen many instances of vibration being set up by a shaft fitted with unbalanced pulleys revolved at high speed.

Hull, Que.—The Hull Iron & Steel Co., will make an extension to their plant to cost about $4,500.

SEEING THE FINISHED JOB

By J. R. H.

AMONG the first things that a young man should acquire, when taking up a vocation, is the ability to perceive with the mind, the final accomplishment of the work he has in hand. The majority of industrial workers of to-day are content to plod along, seeing only with their eyes; their mind either asleep, or wandering in some other channels, foreign to that in which their present labors are engaged.

To successfully achieve anything worth while, the mind and hand should work in harmony, zealously striving to accomplish the end in view. No man can conscientiously perform his allotted duties unless he takes a special interest in every detail. Before a job is ever started, the workman should have a clear conception of the final appearance of the work under consideration. Much time and unnecessary labor is often saved by a little forethought; mental performance of each operation will sometimes eliminate considerable waste of effort, which is often experienced if the work is performed in a haphazard and impulsive manner.

Some years ago a new mechanic was hired by a certain engineering firm. The foreman gave him a large number of shafts to turn, told him to do a specific operation on all the shafts, and when he had that finished, he would tell what operation to do next. This went on, each series of operations being completed until the shafts were finished. It appears that this system had been going on for a long time in this particular shop, but experience had shown the new mechanic that a little thought applied to this job would result in completing the entire work in much less time. When the next batch of these shafts were given him, he understood what was required, and instead of going about it, as others had been doing, he had prepared a method of his own, by which the work was accomplished in one third less time.

What every young man should realize early in his career is that the man who thinks for himself is the one that in time will tower above his fellows. Remember, that while the eyes see only what you are doing, it is the mind that tells you what should, or should not, be done. I was once told that a machinist, when asked why he was doing work in a certain way, replied, "I don't know; ask the boss, I'm only working here." This answer might be true in the case of many men in workshops to-day; but it is also true that while you are working for your employer, you are nevertheless compiling the material that shall make or mar your future life and character.

A man should not only do his work but should study it. He should not be content with the simple knowledge of what he is doing, but should know why he is doing it. The mere fact that the work supports you should not be sufficient; you should support your work; take such an interest in it that the closing hour of the day will come as a surprise, and not as something that is only a relief from a tiresome and arduous task.

While you are at the machine or the bench; keep your mind on your work; not because you are expected to do so, but because it is a duty you owe to yourself. No man can afford to work, for another, if he is not first working for himself. Your present remuneration is for what you are doing; your future, for what you will have learned from the interest, or lack of interest, you are now taking in your daily labors.

Remember the past; study the present; think of the future; and acquire the ability of seeing with the mind's eye that which the hand will ultimately accomplish.

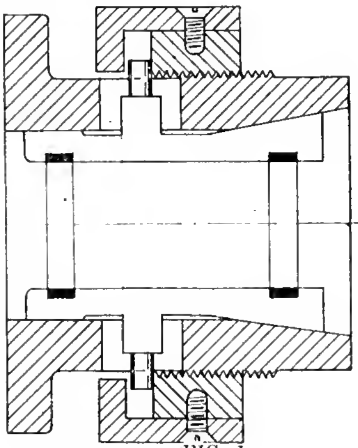

FIG. 1

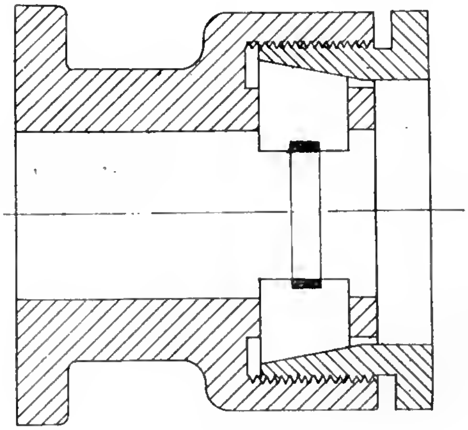

FIG. 2

SHELL MAKING TOOLS

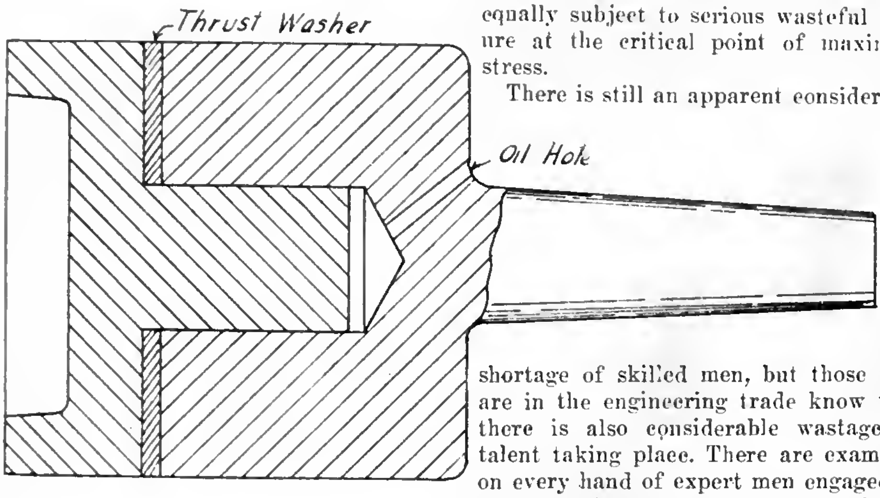
W. J. M.

THE writer has read several of your recent articles describing various items of shell equipment in use in British shell factories, and, while appreciating the interest which this information may have for your readers here in Canada, feels constrained to express the opinion that if the descriptions referred to are typical of British practice, then Canadian manufacturers need not take a back seat for all the munition makers in the world.

The items of equipment described on page 311 of your issue of April 6th prompted the writer to look up the English journal referred to and considerable surprise was felt when it was stated that the entire machine shop of the firm in question was occupied in making more than forty different types and sizes of special chucks and other tools for machining high explosive shells of 3.3 in. calibre and upwards.

Taking the collet chuck Fig 1, in your issue referred to, the design of this article may be alright on paper but in practice it would not be long till its action would become unreliable. The conical collet which compresses the jaws has only a very small bearing on the outside of the chuck to-day. This would have to be made an excellent fit to begin with, and unfortunately, the better the fit the quicker the wear. A degree of slackness is bound to occur through wear on the threads of the right and left hand nut, so that when any unevenness on the surface of the shell caused the jaws to impart a rocking motion to the collet ring the small bearing which it has on the chuck body would soon become inoperative, leaving the collet ring floating in the nut, and the nut floating on the chuck body. The amount of shake possible in this case would then be equal to the sum of the shake in the two threaded diameters, which with a little wear on the threads would soon be beyond the allowed limits of accuracy on the shell.

In the absence of full particulars of the type of lathe used, one presumes that the lathe spindle was solid thus preventing the adoption of a pot chuck with draw in collet actuated by a rod through the spindle such as is in common use on this side of the ocean, but the fact of a solid spindle would not have prevented the use of a draw-in collet chuck if inner ends of the seg-



ments had pins projecting through slots in chuck body to engage on as shown in sketch herewith Fig. 1. Collet chucks, however, are more suitable for use on finished surfaces and if, as is probable the British chuck in question was intended for use on rough forgings, it would be more satisfactory to use a tightening device of the type shown in Fig. 2. This allows the use of narrow jaws for gripping the rough surface of the forging and has the merit of all parts being solid metal to metal without any chance of shake. "The tighter the solider."

The adapter centre described is your article seems to be an unnecessary refinement in view of the satisfactory results obtained in this country with devices having half the number of parts. The designer evidently overlooked the fact that all shells have a considerable radius on the corner of the base, and a simple cup centre of the type shown in Fig. 3, may be found in 90 per cent. of Canadian shell shops on shells up to 6 in. calibre doing excellent service with equal degree of accuracy and a considerable saving of time over the British design referred to.

These are minor points in shell equipment, but their influence on quantity and quality may be quite considerable in the aggregate, and if we are to judge from such information as is available, the Canadian machinist has a lot to be proud of when it comes to shell machinery and devices.

THE THREE-SHIFT SYSTEM

THE extreme pressure imposed on all engaged in the production of munitions of war has compelled every engineering works manager to face extraordinary conditions. It is essential to extract every available ounce of work from men and plant. In this extremity there is always the risk of overdoing the speeding-up; men's physical constitutions and the strength of machines are both equally subject to serious wasteful failure at the critical point of maximum stress.

There is still an apparent considerable shortage of skilled men, but those who are in the engineering trade know that there is also considerable wastage of talent taking place. There are examples on every hand of expert men engaged in munition factories through long hours and working at semi-skilled tasks. They are inefficient in the sense that their class of work could be learned easily and be just as thoroughly done by recruits from the ranks of rough labor. It is in this connection that there is great need of practising labor efficiency, and every works manager should tackle this particular feature for himself in his own works.

There is every reason for giving the subject of shorter shifts for all workers serious attention, apart from the bearing it has upon woman labor. It has been proved beyond doubt that the present customary two shifts per 24-hour day imposes too much upon the worker's constitution. The frequent police court cases arising from laziness and lost time are evidence of the great wastage taking place daily throughout Britain in munition factories.

Two and Three-Shift Comparisons

An actual record of labor efficiency as affected by the duration of working shift is quoted by J. E. Grant in a recent issue of "Engineering." At a particular works the two-shift system was in vogue. This was made up of a day-shift extending from 7 a.m. to 5 p.m., with an hour break, and a night-shift extending from 6 p.m. to 7 a.m., with breaks of an hour and a half-hour. The week's total day-shift time was 50 hours; the night-shift total, 57½ hours. It was found that the output per man per hour on the night-shift was from 15 per cent. to 20 per cent. less than the output per man on the day-shift. It has always been accepted in engineering works that a night-shift cannot give the same rate of production as prevails on day work.

The particular merit of the case quoted by Mr. Grant is that he is able to give a direct comparison of the working of the two-shift and three-shift systems. The latter arrangement was introduced as follows:—First shift, 7.30 a.m. to 4 p.m.; second, 3.30 p.m. to 12 midnight; third, 11.30 p.m. to 8 a.m.; in each shift there was a half-hour break for meals. The total number of hours worked per week was thus increased from 107½ hours to 144 hours—and the efficiency or productive capacity of the machines increased proportionally.

Even more important was the great improvement of the workers' efficiency. It was found that each man in his 48-hour week was doing as much as he did before in his 50-hour day-shift week. The net result of the change has been an increase of 50 per cent. in output. The men are kept running at high pressure, without weariness, but always energetic and cheerful; they are always ready and willing to work on at overtime as occasion may demand. The overhead charges of the machinery are less, due to the increase in working hours. This increased working of the plant necessarily adds to the maintenance charge, but that is much more than offset by the all-round considerable gain in the efficiency of labor and machinery.

Records of actual experience such as this are invaluable to-day. They stand out prominently amongst the innumerable fantastic proposals and suggestions to meet the labor crisis, most of which have a political origin and are not economically practicable. — Manchester Courier.

POTASH AND FELDSPAR

DR. FRANK D. ADAMS, speaking at the recent annual meeting of the Commission of Conservation, said: "A question of great importance is whether we cannot find deposits of potash in Canada. It is practically impossible for us to find deposits of potash similar to the German ones, but, locked up in the rocks of the northern Laurentian country, where we have these great granites, we possess enormous deposits of silicate of potash and feldspar. These are now awaiting the arrival of some one who will invent a method to get supplies from the old granite rocks. Whenever that can be done we will have in the northern country an enormous and inexhaustible supply of potash."

The Port Hope Machine & File Works have taken over J. Helm's foundry and machine shop at Port Hope, Ont., and will conduct a general engineering business. Special machinery is being installed for re-cutting files, which will be the principal branch of the business.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

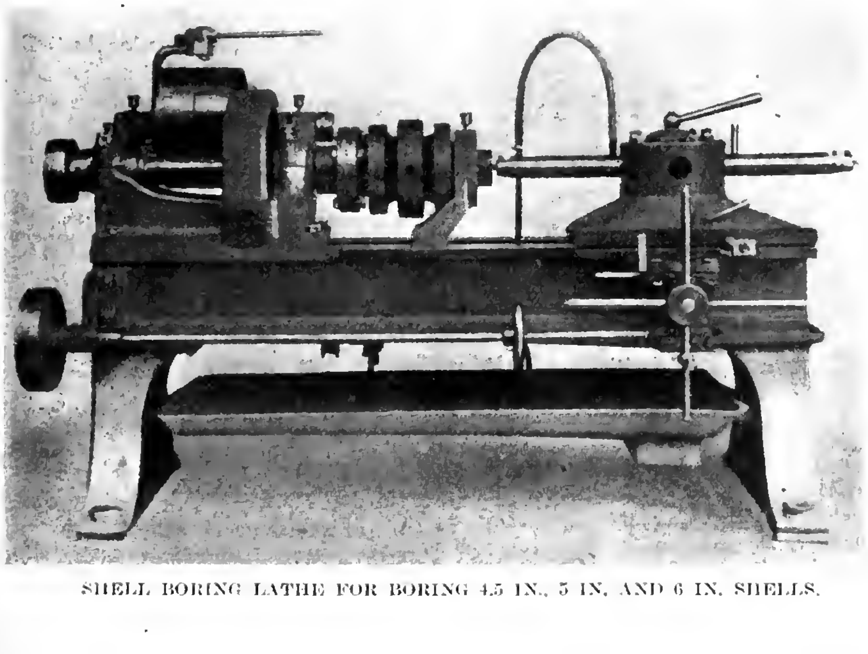
SHELL BORING LATHE

OUR illustration shows a 9-in. centre lathe, designed by the Hunslet Engine Co., Leeds, Eng., for boring 4.5 in., 5 in. and 6 in. shells. These lathes have been specially built for handiness, ease of manipulation and to stand rough usage by unskilled persons. The headstock is provided with a hollow spindle of high-tensile steel running in gun-metal bearings with large ball thrust washers, and is arranged for a single speed. The drive is by means of a fast-and-loose pulley on the back shaft, no countershaft being required. The back shaft bearings are of cast iron, lapped out, and the spindle bearings of Admiralty mixture gun-metal. The turret is of substantial construction, with wide bearing surfaces, and is supplied with four holes to receive the tool bars. The plunger and bushes of the turret stops are of steel hardened, and are ground so as to ensure that the turret may be brought correctly to centre for the different tool bars. The turret saddle is of unusual length and the projecting end passes under the chuck, which enables the turret to be brought close to the chuck.

The feed motion is arranged for one rate of feed only, and the shafts for the feed gear are covered by the saddle to prevent chips getting into and damaging the gears. The rack is arranged in the centre of the bed so as to give a central thrust to the slide, and the steel feed rack which actuates the turret slide is inverted so that chips are unable to enter. An automatic adjustable stop is fitted to the slide feed. The feed gears, with the exception of the worm wheel and clutch, are arranged inside the bed, but are easily accessible. They are forged solid, so as to eliminate shaft keys. The whole of the feed gear is made of high tensile forged steel. There are three feeds as follows:—Automatic fine hand and quick hand.

For shell boring the fine hand feed is necessary. The automatic feed is disengaged when the boring bar is nearing the bottom of the shell and the fine hand feed is then used for the bottom-forming operation. The following are the leading particulars of this lathe:

Height of centres, 9 in.; length of bed, 7 ft.; diameter of holes in turret, 2¾ in.; gear ratio, 5 to 1, 6½ to 1; diameter of driving pulleys, 1 ft. 3½ in.; width of driving pulleys, 5¼ in.; width of driving belt, 5 in. size of main spindle bearing, large end 4½ in. diameter by 5½ in., small end 3¼ in. diameter by 5 in.; diameter of hole through spindle, 1½ in.; speed of main spindle, 35 revolutions per minute; speed of back shaft, 175 to 227 revolutions per minute.



SHELL BORING LATHE FOR BORING 4.5 IN., 5 IN. AND 6 IN. SHELLS.

AUXILIARY HEAD FOR MILLING MACHINES AND LATHES

AN auxiliary head for use in milling machines and lathes is manufactured by Edgar W. Bemis, Worcester, Mass. It is made in two styles, on of which employs standard collets from ⅛ in, to ⅞ in., and the other a threaded plug adapter which is interchangeable with the collet. The main sleeve revolves in the casting and is flanged at its upper end to take the downward thrust when cutting. It is retained in place by the threaded collar on its lower end. A dividing plate with spring plunger for locating it by slots is mounted on the centre of the sleeve, being kept from turning by a key.

AUXILIARY HEAD FOR MILLING MACHINES AND LATHE

This plate is interchangeable, and by the use of suitable plates, a great variety of operations can be quickly performed. Straddle milling nuts of all kinds, either square or hexagon squaring heads of poppet screws, planer bolts, ends of taps, etc., cutling multiple threaded screws on the lathe, and drilling holes on circles, etc.

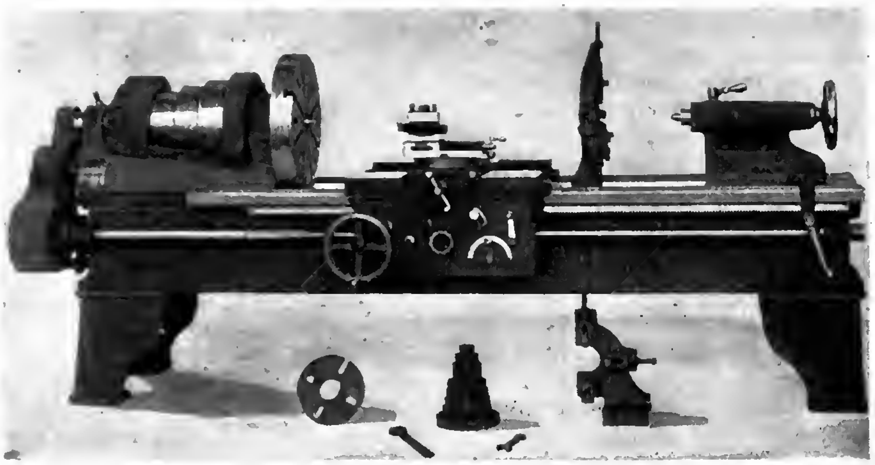
22 IN. ENGINE LATHE

THE engine lathe shown in the accompanying illustration is built by the Davenport Locomotive Works, Davenport, Iowa, and is designed for extra heavy service. The headstock is of conventional design, fitted with a three-step cone and double back-gears giving nine speeds in geometrical progression. The hollow spindle is made of .50 carbon steel, with ground bearings running in bronze boxes.

Semi-steel is the material of which the bed is formed, the section of the bed being unusually heavy and rigidly braced with cross girths. The tailstock is of the cut-away type with set over adjustment for taper turning.

The driving cone has 14, 12, and 10 in. dia. steps for 4 in. belt, the ratios of the two back gears being 12.58 to 1 and 3.56 to 1. No. 5 Morse taper centres are

fitted. The carriage has a long bearing on the two vees, has tee slots and a flat top. Apron is of the double wall type, and is arranged so that the cross feed and lateral feed cannot be engaged simultaneously. All feed gears are of



22-INCH ENGINE LATHE FOR EXTRA HEAVY SERVICE.

steel. Change gears supplied enable threads to be cut from 2 to 18 per inch, including 11½.

The countershaft is of the double-friction type with 14 in. pulleys, and the equipment includes 1 large and 1 small face plate, 1 steady and 1 follow rest, and necessary wrenches. With an 8 ft. 3 in. bed, this lathe takes in 3 ft. 3 in. between centres and weighs 5,200 lbs.

DIE-FILING MACHINE

A MOTOR-DRIVEN die-filing machine of interesting design is illustrated herewith. The main frame which encloses the mechanism is arranged to tilt over on the base, being supported on a curved seat and secured in the desired position by two thumb-screws. The reciprocating mechanism consists of a shaft, the outer end of which carries the belt pulley, and the inner end a crank disc with crank pin. The chuck for holding the file is mounted on the upper end of a reciprocating shaft or pitman, the lower end of which extends down past the inner end of pulley shaft, and enters a bushing with connecting passages so formed that the rod end acts as a plunger pump, distributing oil over all of the working parts. A cross-head mounted on the pitman engages with the crank pin.

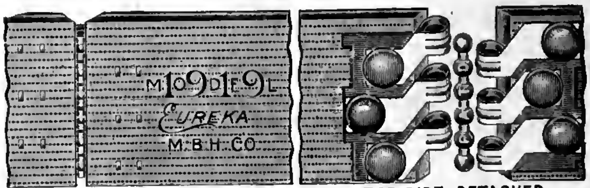
This pump action serves the further purpose of taking up the impact of the pitman and renders the operation of the machine very smooth. The machine uses standard files of the form made for use on die-filing machines, and the chuck is designed to give a three-point contact on the round shank of the file. The table can be tilted in relation to the file so as to give draft in either direction.

Table diameter is 9 in.; stroke of spindle 1 in.; height, 12 in.; space occupied, 10 in. x 16 in.; weight, 54 lbs. Belt drive furnished when required. The makers of this machine are the Illinois Tool Works, Chicago.

MOTOR-DRIVEN DIE-FILING MACHINE.

A BALL BEARING BELT COUPLER

A BELT coupler possessing interesting features of construction is offered to belt users by the Manufacturers Belt Hook Co., Chicago. The device is adaptable to all kinds of belting, and consists of steel clasps for the belt ends, and a steel spindle with ball-shaped swellings, each of which is enclosed by a section of the clasp. The clasp sections are steel stampings, one end being formed with hooks, which are driven into the belt



PULLEY SIDE, ATTACHED — TOP SIDE, DETACHED

when the other end is riveted on top with a bifurcated rivet which clinches on the lower surface of the belt.

The result of this construction is to give a ball bearing, noiseless, detachable, flexible steel belt lacing which can be attached with a hammer and used over again when required.

Electrically-Heated Soaking Pits.—Electrically-heated soaking pits for ingots, in place of the fuel-fired ones, are attracting interest in the steel world, says the Iron Age. Our contemporary gives a few figures concerning the electric soaking pits invented by T. F. Baily, president of the Electric Furnace Co., Alliance, Ohio, and adds that these can compete with gas-fired pits even where moderately hot stripping and charging is practised. The electric pit further has the advantage of a non-oxidizing atmosphere, which means a saving of from 1 to 2 per cent. of the weight of ingots put through the pit. It also takes only one-third the space occupied by a gas-fired pit of the same capacity. A feature of still greater importance is the elimination of surface defects in the ingots.

WORLD'S INDUSTRY IMMEDIATELY FOLLOWING PEACE DECLARATION

SIGNS are not wanting, that the period of transition through which the world's industry must pass after the war, is engaging the earnest attention of all students of political economy. The situation is altogether unparalleled, and, in the absence of any exact precedent, many opinions are being expressed in which the wish is father to the thought. The hope is cherished in the minds of the general public that, because in the past conflicts between nations have been followed by periods of extreme activity and reconstruction, so the present world conflict will be followed by a similar reaction or condition of things. The hope is worthy of all commendation and while trusting that it will be fully realized, the fact remains that there is one vital difference which prevents an exact parallel being drawn between the present and any former period.

During the American Civil War, for instance, while the declaration of cotton as contraband was a serious blow to the financial resources of the Southern States, its effect on many thousands of England's industrial workers were what might aptly be termed disastrous. There was no increased activity in other branches of British industry to offset the trade depression or mitigate the personal privations endured as a result of this action. War orders from either the Federal or Confederate States did not even mount into millions, much less into hundreds of millions, as orders from the Allies meantime do. Consequently, the chief factor in American industrial activity following the Civil War was the realization of the value of the natural resources of the country. The value of these as a national asset was indispensable in placing the credit of the country on a sound basis, to be immediately followed by an industrial development, the natural sequence to the conditions. An influx of European capital was also greatly facilitated.

Whatever the outcome of the war, it hardly seems probable that history will repeat itself. When peace reigns again Europe will not be in the position of a young country with undeveloped resources. With more than half her constituent nations bankrupt and the whole more than half bankrupt, and assets consisting principally of exhausted credit and broken men, the probabilities of a rapid recovery seem to be rather remote.

Bitter as was the Civil War, and difficult the reconciliation, they are quite o'er shadowed by the present breach of national faith and the revulsion which will exist throughout the civilized world towards the Teutonic race, probably for centuries to come.

That this national ostracism will militate against the resumption of the 'status quo ante' of the world's trade, cannot be gainsaid. If, in considering future industrial conditions, Canadian manufacturers desire to form an analogy between past and present, then they and not Europe will be the favored part of the world. The transference of sums of money, vast beyond imagination, from Europe to America will continue till a decision is reached in the conflict. By that time the United States will have an immense amount of unemployed capital for the investment of which there will be no domestic demand.

Its manufacturing resources in constructive industry like those of Canada have been developed to an extent beyond all possible permanent requirements. What then will be the probable ultimate rearrangement of the world's industrial power? The inevitable delay in the resumption of peace conditions and the temporary dislocation of various industries will be largely mitigated by the readiness with which Canada and the United States show their appreciation of the situation.

The utilization of Canada's industrial and agricultural resources will be due to her position in and efforts on behalf of the Empire . The United States will be compelled by internal economic conditions to maintain its present activity by participating as far as possible in European reconstruction. Such participation will, however, be limited by the necessity of conserving Allied credit. As an integral part of the British Empire, this country will be in a position to benefit from probable fiscal developments which will balance to a desirable extent the preponderance of wealth and industry which war conditions have created in our southern neighbor.

GENERAL BUSINESS CONDITIONS

A GRATIFYING feature of the present industrial situation is the steady improvement in domestic business, due to the prosperous condition of the country. The outlook for an increase in exports, other than munitions and war supplies, has improved considerably and manufacturers are looking for more important developments. The spring weather has had a stimulating effect on many industries and the outlook generally is distinctly favorable. Navigation will be open on the Lakes and St. Lawrence very shortly, which will considerably relieve the congest of freight at railroad terminals. The situation in this regard has been getting more and more acute and has caused considerable delay to shipments and inconvenience to merchants. The customs returns for Toronto for the fiscal year which ended on March 31, are almost two million dollars in excess of the greatest previous year in the history of the port. There has been a very marked gain in revenue since September, and March showed the largest increase for any month.

Manufacturers are concerned over the shortage of labor which is beginning to be felt, and which will become more serious as the number of battalions for overseas increases. The shortage of raw materials is also becoming a serious question for manufacturers to contend with, in addition prices are still rising, thus increasing the cost of production. The upward trend in prices of finished products continues, a number of advances having been made during recent weeks.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., April 10, 1916.—Gradual improvement is reported in many branches of domestic activities. While the bulk of present business is largely that of war supplies and munitions, it is encouraging to note the constant and ever increasing volume of industrial activity which is developing, indirectly, from war conditions. The Canadian manufacturer is alive to future possibilities, and no time is being lost in acquiring a large portion of new business, which must ultimately be transacted in new fields.

Present weather conditions point to the early opening of navigation, which will materially aid in the present congested state of shipping facilities.

Pig Iron

No change is noted in the pig iron situation. Furnaces continue working to capacity in supplying the requirements of the steel producers. United State's prices are very firm. Philadelphia price on No. 2 foundry, shows an advance of $5. per ton.

Steel

The general condition of the steel situation is one of comparative quiet, but no indication of weakness is shown. The mills in most cases are well sold for the remainder of the year, and buyers are also well covered for a greater portion of the same period. There is a feeling abroad that the top of the market, if not already reached, is close at hand; and while further advances will likely be reported, they are expected to be on commodities which have been dragging behind the general market. No change is reported in unfinished steel prices, with the exception of forging billets which are now quoted at $75 per ton. Heavy rail orders during the past month have resulted in an advance of $5 per ton and Pittsburg prices are now 2.10c and 2.15c with possibilities of further advances. Iron bars, with an advance of $2 a ton are quoted at 2.60c Pittsburg. The price on steel hoops is now $3 per hundred, an increase on the week of $5 a ton. Galvanized sheets are very quiet, but increased activity is noted in black and blue annealed sheets; No. 28 Pittsburg black is now quoted at 3.10, an advance of $2 a ton and blue annealed has advanced 75 cents per hundred, this week's price being $3.75. Wire products have been advanced 10 cents per hundred.

Metals

The general tone of the metal market is one of strength, not that any exceptional developments have transpired to change the situation, but the feeling is abroad that a period of activity is close at hand. Large quantities of copper have been ordered by the French and British governments and with additional domestic requirements, the situation is taking on strength. The tin situation is being affected by the shortage of ocean bottoms and the market is high and uncertain. Domestic spelter is quiet, but foreign demand is strong while prices have an upward tendency. Lead continues very firm and the demand is heavy.

Copper.—The recent activity in the market, following the previous quiet period of a couple of weeks ago, has had the effect of strengthening the present copper situation. During the past two weeks the French government have contracted for approximately 35,000,000 lbs., and the British authorities have just recently placed orders, for this years delivery, to the amount of 60,000 tons of metal. This foreign demand, with the increased requirements of the home markets has resulted in one of the greatest buying movements in the history of the copper trade. London cables report an advance on last week's quotation of £2 on all coppers. Standard spot is now quoted at £118, futures at £115 and electro spot at £134; this last however is a decline of £1 over the previous day's figures. New York prices on lake and electrolytic are ¾ cent per pound higher, present quotations being 28 cents for each. Castings, quoted at 26½, show an advance of ½ cent per pound. Consumers are continuing to cover their requirements for many months ahead, and present indications are a future shortage of metal. The present copper situation is in a stronger position now than at any time since the opening of the war. Local dealers report a good market with prices firm and nominal at unchanged prices of 31 cents for lake and electro, and 30 cents for castings.

Tin.—The upward movement in tin continues and prices are gradually ad-

vancing, both on this side and on the British markets. The chief cause of the strong tone is the small arrivals of tin shipments, and indefinite information regarding new arrivals. The inability to calculate the time of arrival of tin bearing vessels from the east is keeping the market in a strong condition. In addition to this the demand is expected to increase during the next few months, and unless some relief is shortly announced, further advances are expected. London prices are quoted at £202 for spot; £196 for futures; an advance of £3 and£2-15 respectively. Straits tin, with an advance of £2 is quoted at £202. The New York market is quoting the nominal figure of 53½ cents per pound, being an advance over last week of 4½ cents. The nominal price of 51 cents is being quoted, for early delivery.

Spelter.—The market is very firm following a good export demand. The domestic requirements are fair and future demand has so far been light. It is reported that foreign demand has resulted in considerable tonnage being contracted for, and any large amount of home buying under present conditions, would likely be followed by further advances, as producers seem in no mood to sell freely. The British situation is undergoing some uneasiness at the present time, and while the price on spot and early spelter is lower, considerable inconvenience is being experienced by many consumers, owing to non-arrival of contracted supply, due to inadequate shipping facilities. London quotation for spot spelter is now £94, and futures £84. New York quotes the nominal price of 18.80 for prompt shipment. Local conditions are unchanged and prices firm at 23 cents per pound.

Lead.—The recent upward rush has apparently settled down, but it is not expected that any immediate weakness will be shown. The present high tone of the lead situation is largely influenced by the excessive consumption for munition purposes. Certain British regulations have a tendency to limit the business, but the quiet and steady demand from the far east is keeping the markets in a firm and steady condition. In the hope of creating new business some dealers are offering slight concessions to buyers. The London market has declined 27 shillings on spot and £33. 10s. and £33. 15s. respectively. The Trust price remains firm at 7½, while the outside interests have declined ¼ cent and are now quoting 7.875 per pound. Local prices are steady at 10 cents and conditions are unchanged.

Antimony.—The market is comparatively quiet and prices are holding firm. Consumers are only covering their immediate requirements and heavy trading is practically at a standstill. The nominal price of 48 cents is being quoted.

Aluminum.—The market is quiet and prices remain unchanged at 68 cents a pound.

Machine Tools and Supplies

Activity in the machine tool industry is becoming quieter, and normal conditions are gradually asserting themselves. However, the requirements of the shell producing shops are continually calling for additional tools which will keep the machinery builders from being idle for many months to come. In some respects the needs of new industries will somewhat compensate for the falling off of munition demands. Many manufacturers are building or contemplating building additions to present factories, in anticipation of future requirements. The small supplies market is exceptionally active, and the demand for small accessories is very heavy, it being almost impossible for manufacturers to supply the full requirements of the trade.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Old Materials

The trade in scrap metals is very active and business is reported good. Prices for old copper have advanced and the demand is heavy for all grades of old copper, crucible at 21½ cents is ½ cent stronger; heavy copper and copper wire with an advance of 1 cent are quoted at 21¾ cents per pound. Old stove plate is in good demand and this week's quotation of 10½ cent shows an advance of 1 cent per pound. New York prices on old materials show considerable increase on copper and lead scrap, and aluminum has jumped from 2 to 5 cents per pound 2 cents for old and 5 cents for new scrap.

Toronto, Ont., April 11.—No better indication of the prosperity which the steel and engineering industries are at present enjoying can be found than in the annual reports of the various companies which have been issued recently. The most interesting statements since the Nova Scotia Steel & Coal Co. and Canadian General Electric reports were published have been those of the Steel Company of Canada, the Canadian Fairbanks-Morse Co., and the Canada Machinery Corporation. In all these cases handsome profits have been made, and the companies placed in a sound financial condition. These satisfactory results have, of course, been obtained in abnormal times, but the benefits derived will be of the greatest possible assistance in maintaining the stability of these concerns after the war, when business will probably be dull for a time until the situaton is adjusted and conditions become normal again. A number of smaller, but none the less important companies, are also very prosperous, and have benefited considerably by making munitions or machine tools for munition plants.

Business generally continues to improve and the outlook is bright. The Dominion revenue for the fiscal year ending on March 31st shows an increase of $39,550,000 over the previous twelve months. For the month of March the Customs revenue totalled nearly ten million dollars, being an increase of over two millions more than the corresponding months of last year. There is no sign of any recession in any market, and prices continue to advance as raw materials continue to rise and are becoming more difficult to obtain. The principal advances this week include wrought iron pipe, bolts and nuts, shafting, files, black sheets, some oils and compounds, wire nails, tin, and spelter.

Steel Market

The situation in the steel trade continues very satisfactory, and the market is strong, with prices still rising. The extremely satisfactory annual statement recently issued by the Steel Company of Canada is an indication of the prosperity which prevails in the steel industry. Not only are the steel companies in excellent shape financially, but they have all made important additions to their plants, which are in good condition. The output of the mills is sold up to the end of this year, which is a guarantee of continued activity and large earnings. Although prices have an upward tendency, there is a general feeling that they are quite high enough. It is largely a matter for speculation as to when the top will be reached, and there is no indication at the present time of a halt in the upward movement.

Prices of some iron and steel products have advanced. Wrought iron pipe has been affected, black pipe having advanced two points for all sizes, and galvanized six points for ¼ in. and ⅜ in., and three points for all the other sizes. The new prices are given in the selected market quotations. Cold rolled shafting is higher, the new price being list plus 30 per cent. at warehouse and list plus

20 per cent. at mill. The prices are for delivery at mill convenience. A new list of discount for bolts and nuts has been issued. Wire nails have advanced 25c, and are now quoted at $3.65 per keg base. This advance is due to the increase in cost and great scarcity of wire rods. A sharp advance in boiler tubes may be expected any time, and higher prices for cut nails are likely in the near future. Mild steel and iron bars are unchanged at $3 and $2.75 per 100 pounds, but higher prices have been made in sleigh shoe steel at $3; reeled machinery steel at $4.50; toe calk steel at $3.95, and spring steel at $4.50 per 100 pounds. Mining and silver tool steel are higher at 10c and 18c per pound respectively.

The galvanized sheet situation is unchanged, and the market continues strong. Spelter is too high to be attractive and black sheets are advancing steadily, thus curtailing production of galvanized sheets. Prices are unchanged in the meantime, but an advance in the near future is highly probable. The big demand for black and particularly blue annealed sheets in the primary market has caused an advance in prices, and is also making deliveries more backward. Black sheets, No. 28 gauge, are quoted locally at $4, and No. 10 gauge at $4.50 per 100 pounds.

An interesting feature in the steel market in the United States is the possible advance in the price of rails. The base price of steel rails has stood at $28 per ton for over fifteen years, but owing to the unusual conditions prevailing in the trade a change will probably be made after May 1. The situation in the steel trade generally is unchanged, the demand being as insistent as ever. It appears likely that prices will remain high for this year, as the mills have enough business booked to practically carry them over the remainder of the year. Some authorities, however, believe that there are indications of a possible recession of prices. The production of billets is increasing, so is also the demand. Bessemer and open-hearth billets are unchanged at $45 per ton, but forging billets have advanced to $67.50 per ton, base, Pittsburgh. Wire rods have also advanced, and are now being quoted at $60 per ton Pittsburgh. The ferromanganese situation continues acute, and very high prices are being paid for prompt shipments; prices ranging all the way from $4.00 to $4.50.

Pig Iron

The price of grey forge pig iron has advanced 25c to $18.70 f.o.b. Pittsburgh. Hamilton and Victoria pig irons are unchanged at $24 per ton. The demand for steel-making pig iron is extremely heavy, while there is a marked improvement in the demand for foundry grades.

Old Material

The market is holding firm, with a tendency towards higher prices. Business is showing some improvement, particularly in copper, which is in good demand.

Scrap lead is very firm in sympathy with the pig lead market, but prices are unchanged. Prices of light copper, machine composition, composition turnings, brass clippings and brass turnings are about 25c per 100 lbs. higher. Heavy melting steel is firmer and the position of this material is improving.

Machine Tools

Conditions in the market are much the same as they have been for some weeks. The demand continues fair, and is almost entirely for munitions plants. A number of firms who have hitherto been making 18-pdr. high explosive shells are equipping their plants for handling 4.5 in. shells. Machine tool makers are very busy on equipment for shell plants. The Canada Machinery Corporation have issued an interesting statement, which indicates that machine tool makers are enjoying a period of prosperity.

Supplies

Business continues good and the situation unchanged. Prices on all supplies are very firm, and advances in some lines, such as white lead, gasoline, benzine and solder, are expected. Only a few changes of any importance have been made this week. Plumbers' oakum has advanced 1c, and is now quoted at 7c per pound. Some makes of files have advanced from 70 per cent. to 65 and 10 per cent. discount. Some oils and cutting compounds have advanced. Machine oil is now quoted at 26½c; lard oil, $1.35; thread-cutting oil, 35c, and quenching oil, 38½c per gallon. Standard cutting compound is quoted at 6c per pound. Turpentine and linseed oil are steady and unchanged.

Metal Market

The demand continues active for metals for munitions, and the consumption for other purposes is steadily improving. The feature this week is a sharp advance in tin, following an upward movement in London and Nw York. The position of tin has improved considerably, and it is expected that the market will go still higher. Lead is unchanged at the high level reached during last week, but the market is a little easier. The copper situation is unchanged, but the market is very firm and quotations are still nominal. Large contracts have been placed for copper in the United States by the British and French Governments, which has strengthened the position of this metal. The demand for spelter is heavier and the market firm, with some possibility of higher prices. The antimony situation is unchanged, and there is nothing of particular importance to note with regard to this metal. The same may be said of aluminum, which is still very scarce and high in price. Solders are unchanged, but higher prices may be looked for, particularly now that the tin market is rising.

Copper.—The most interesting feature in the copper market is the announcement that the British and French Governments have contracted for a very large amount of copper in New York. It is said to be the largest tonnage of copper that has ever been sold in the States. The transaction has not as yet affected prices materially, but will have a tendency to keep the market firm for several months, and may eventually cause higher prices. Locally the market is firm and unchanged at 30½c per pound nominal.

Tin.—Tin is higher locally, following an advance in London and New York. The strength in the market is due to increased consumption and scarcity of spot metal. New York market is also being affected by the difficulty in getting permits to ship from England, which is interfering with business. Tin has advanced 4c, and is now quoted at 58c per pound nominal.

Spelter.—The market is firm and higher in New York on account of a good demand for spelter, particularly for export. It is said that producers are holding back and offering less spelter now than they have done in a long time, both for nearby deliveries and futures. Spelter has advanced locally, and is now quoted at 23c per pound.

Lead.—The market is dull and easier after the recent advance. The "Trust" price is being held at 7.50c New York, but the open market is weaker, the price ranging from 7.62½c to 7.87½c. The lead situation is unchanged, and the demand continues heavy. Lead is unchanged locally at 11c per pound.

Antimony.—The market is featureless and quotations nominal at 48c per pound.

Aluminum.—The market is quiet and easier. Quotations have a weaker tendency, but are in the meantime unchanged and nominal at 68c per pound.

CANADIAN FAIRBANKS-MORSE YEAR

ANOTHER striking example of the astonishing change that the past year worked in the fortune of Canadian industrials is furnished in the annual statement of the Canadian Fairbanks-Morse Co., Ltd., which shows a net profit of $709,048, for 1915, against a net loss of $101,099 in 1914.

After providing for preferred stock dividend the 1915 balance available for distribution on the common stock was $619,048, against a deficit of $191,099 the previous year. In 1913, the corresponding balance was $134,792, and $340,428 in 1912—the last named year probably representing a high level in the company's earning power up to the year just closed.

Earnings on the common stock last year work out to 38.7 per cent., and in view of the fact that common stock dividends, formerly at the rate of 8 per cent. per annum, had to be discontinued in 1914, the directors have treated shareholders generously. In addition to a cash dividend of 4 per cent. paid during the year, they have declared a dividend of 12½ per cent., payable in Canadian war loan bonds. This still left $361,338 to be added to surplus, more than doubling that account. Comparisons of profit and loss figures for three years follow:

	1915.	1914.	1913.
Profits	$709,048	*$101,099	$224,792
Pref. div.	90,000	90,000	90,000
Balance	$619,048	†191,099	$134,792
Com. dividend	257,710	......	128,000
Balance	$361,338	†$191,099	$ 6,792
Prev. balance	336,498	527,598	520,805
Surplus	$697,836	$336,498	$527,598

*Loss. †Deficit.

The company was notably fortunate in that it shared in the two main sources of business improvement in Canada last year—munition manufacture and record-breaking grain crops. "As anticipated," says H. J. Fuller, president, in his annual report, " our business during the early part of 1915 was in comparatively small volume, but as the year progressed the demand for machine tools and supplies for munitions factories in the East was of large and increasing volume, and we reaped the benefit of our large inventories and our ability to make prompt delivery.

Reference is made to the company's success in the manufacture of shrapnel shells, started in the fall of 1914. The company expects to be making substantial shipments of large size howitzer shells at an early date, the equipment having been installed in the latter part of 1915. Bank loans which were reduced from $780,133 to $557,048 in 1914, were wiped out altogether during the past year. Current assets foot up $3,517,497, approximately seven times current liabilities of $751,460. Current assets were increased about $360,000 in the year, while current liabilties were reduced $176,000. Against $120,436 in cash at the end of 1914, the present statement shows $308,083, in addition to $20,000 paid on the company's war loan subscription. The balance sheet also shows that depreciation resrve was increased by about $90,000 in the year, while capital assets were written down about $63,000.

The balance sheets of the past two years show the following comparisons:

Assets.

	1915.	1914.
Plant, etc.	$1,292,984	$1,355,211
Inventories	1,269,543	1,668,313
Accounts receivable	1,562,243	1,096,596
Bills receivable	357,626	324,309
War loan	20,000	......
Cash	308,083	120,436
Def. charges	62,795	30,450
Deposits	......	1,868
Totals	$4,873,276	$4,597,186

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Hamilton, Ont.—The Canada Wire Goods Co. will build an addition to their plant.

Galt, Ont.—The Perfect Machinery Co. will build a factory, to cost $5,000. S. L. Clarke is manager.

Toronto, Ont.—L'Air Liquide Society will make an extension to their factory on Boler St., to cost about $3,000.

Fassett, Ont.—The Standard Chemical Co., will rebuild their plant here which was destroyed by fire recently.

Halifax, N.S.—The Halifax Electric Tramway Co., will build a by-product house and a cold storage building at their gas plant.

Welland, Ont.—The Volta Mfg. Co. has purchased a site here, and will build a machine shop for making electrical appliances, etc.

Wallaceburg, Ont.—The Wallaceburg Brick Co. is in the market for a single-cylinder, 50-hp. or over, stationary, natural gas engine.

Donnacona, Que. — The Donnacona Pulp & Paper Co. are erecting a new building, 425 feet by 50 feet. The cost is estimated at $100,000.

Brockville, Ont.—The Canadian Foundries & Forgings Co. will build an addition to its tool department to take care of increased business.

Toronto, Ont.—A. R. Clarke & Co., will erect a one-storey frame and galvanized iron enamelling shop on Eastern avenue, at a cost of $5,400.

Amherst, N. S.—The Ledcote Co., of Canada Ltd., has taken over a property here and is installing plant for covering sheets, etc., with lead as a substitute for galvanizing. William Knight is president of the concern.

Sudbury, Ont.—The Sable River Mining Co., are installing a "Callow" 50-ton flotation plant at their property near Massey Station. The plant is for treating copper ores, and will have a capacity of 50 tons per day. J. F. Flynn is manager of the Company.

Sherbrooke, Que.—A proposal is under consideration to develop power at Westbury Basin for an ultimate capacity of 5,400 h.p. at Westbury Basin switchboard and 5,000 h.p. at the switchboard at Sherbrooke substation. The cost of power equipment and erection would be $77,800 and for the complete development including excavation, buildings and transmission lines, etc., $305,567.

Electrical

Appin, Ont.—The Village Council may install an electric lighting system.

Cobalt, Ont.—The Northern Ontario Power Co., will call for tenders on the construction of a 60 mile transmission line to Kirkland Lake. Complete equipment will be required.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

General Industrial

Paris, Ont.—Penman's Ltd., will build an extension to their factory here at a cost of $15,000.

Hamilton, Ont.—The Skedden Brush Co. will build a factory here at an estimated cost of $3,000.

Toronto, Ont.—The Comfort Soap Co. are making an addition to their factory on Eastern avenue, at a cost of about $4,000.

Toronto, Ont.—William Neilson, Ltd., will make an extension to their candy factory on Gladstone avenue to cost about $25,000.

Weston, Ont.—A. B. Moffatt, representing the Pellatt estate, appeared before the council on April 4, and asked that a final assessment and water power be granted to a large manufacturing firm that contemplate locating here.

Welland, Ont.—The Business and Industrial Committee at a meeting held recently authorized Chairman George Clarke and Mayor Clendenning to negotiate with the Perfection Tire and Motor Co., which seeks to establish a branch plant in Canada.

Municipal

Quebec, Que.—The City Council will call for tenders for 2,000 feet of fire hose and a large quantity of copper wire.

Sault Ste. Marie, Ont.—The City Council are considering the construction of a waterworks system, estimated to cost $300,000.

Toronto, Ont.—The City Council has decided to build a subway under the Grand Trunk tracks on Ashdale avenue, Norway. It will cost approximately $33,000, and will be 8 feet by 12 feet.

Tenders

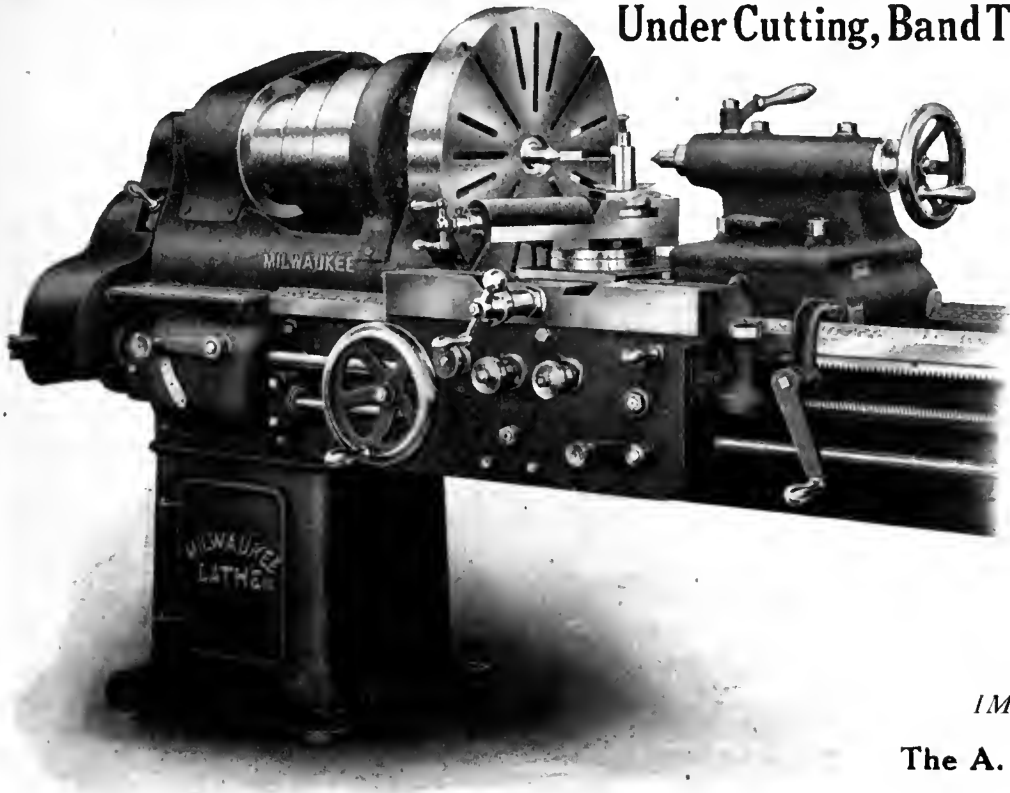
Halifax, N.S.—The Halifax Electric Tramway Co. are calling tenders on elevating and conveying machinery for their new gas plant. Engineer, H. R. Barrett.

Calgary, Alta.—Tenders, addressed to the City Commissioners, will be received up to Monday, April 17th, 1916, for the manufacture and delivery of direct current circuit breakers. Specifications, etc., may be obtained at the office of the City Electrical Engineer.

Kenilworth, Ont.—Tenders will be received up to April 17, for the erection of a number of small bridges and culverts in the Township of Arthur. Specifications, dimensions, etc., may be seen at clerk's office, Kenilworth. A. Hellyer, Township Clerk.

Calgary, Alta.—Tenders sealed will be received until April 15 for the supply of all materials, tools and labor necessary for the construction of one to fourteen elevators. Plans and specifications

24″ Standard Milwaukee Lathe for Finish Turning, Wave Grooving, Under Cutting, Band Turning and Rectifying



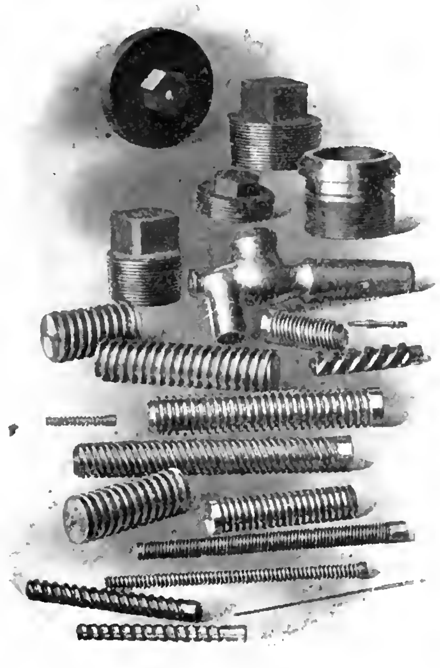
SPECIFICATIONS:

Swing over Bed.....	24½″
Swing over Carriage	15¾″
Dimensions of Front Bearing	3¾″ x 7″
Dimensions of Rear Bearing	3″ x 5″
Hole through Spindle	2 1-16″
Diameter of Spindle Nose	3½″
Pitch of Thread on Spindle	5
Diameter of Tail Spindle	2¾″
Taper Hole in Spindle Bushing.	No, 5 Morse
Cone Diameters ...	9¼″, 12⅛″,15″
Width of Steps on Cone	4⅛″
Ratios of Back Gearing	3.45 to 1 & 12 to 1
Length of Carriage	30″
Width of Bridge	9½″
Pitch of Lead Screw	4
Cut Threads from	1 to 16
Size of Turning Tool	¾″ x 1⅜″
Depth of Bed	15″
Width of Bed	20″
Length of Tail Stock on Bed	17″
10′ Bed takes between Centers, with Tail Stock even with end of Bed	5′ 6″
Countershaft Pulleys	16″ x 6″
Countershaft should run ...	150
Net Weight with 10′ Bed..	5,600 lbs.

IMMEDIATE DELIVERY

The A. R. Williams Machinery Co.
Limited
TORONTO CANADA

A THREAD IS A THREAD



A Thread is a Thread to a Geometric Die Head—Long threads or short, heavy or light work, large diameters or small, fine threads or coarse—they are all alike to the Geometric Die Head.

Whatever the make of your Screw Machine, a Geometric Self-opening and Adjustable Screw-cutting Die Head can be furnished to fit it.

Take up your threading proposition with us. Get acquainted now, and when in need of Screw-cutting Tools, you will find a Geometric the friend, indeed.

Let us know the class of screw-cutting that interests you, and we will send booklet describing the type of tool that is best suited to it.

The Geometric Tool Company
NEW HAVEN, CONN.

Canadian Agents:
Williams & Wilson, Limited, Montreal
The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg, St. John, N.B.

can be obtained upon application to the Alberta Farmers' Co-operative Elevator Co., Calgary.

Quebec, Que.—Tenders for freight shed and grain galleries will be received at the Quebec Harbor Commissioners' Office, Pointe-a-Carey Wharf, Quebec, up to April 15 next. Plans and specifications of the contemplated work may be seen at the harbor engineer's office, Pointe-a-Carey Wharf St. George Boswell, chief engineer.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received up to April 17, 1916, for the supply of Watt-hour meters for the City Light and Power Department for the period of one year from date of contract. Specifications and form of tender may be obtained at the office of the City Light and Power Department, 54 King street.

Winnipeg, Man. — Tenders addressed to the chairman, Board of Control, will be received up to April 17, 1916, for the supply of overhead and indoor construction materials for the city light and power department for the period of six months from the date of contract. Specifications and form of tenders may be obtained at the office of the City Light and Power Department, 54 King street.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received up to April 17, 1916, for the manufacture, delivery and installation in the King street Sub-Station of 3-1,000 k.v.a. transformers with switching apparatus complete. Specifications and forms of tender may be obtained at the office of the City Light & Power Department, 54 King street.

Vancouver, B.C.—The British Columbian Fisheries, Ltd., will sell their entire plant and equipment, including buildings, machinery, tools, refrigerating plant, sawmill and machinery ,fertilizer plant and equipment, power plant equipment ,steam trawlers and scows, etc. Tenders will be received up to April 15, and full particulars may be obtained from James Keppel Ball, Yorkshire Building, Vancouver, B.C.

Toronto, Ont.—Tenders addressed to the secretary-treasurer, Board of Education, will be received until April 13, 1916, for the following trades: For completion of Administration Building, College street; ornamental iron work, spiral stairs, iron railings, etc., elevator, ash hoist, vault doors, hardware trimmings, also for temperature regulators for Dewson street school. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received up to April 17, 1916, for furnishing the City of Winnipeg with the following supplies as required during the six months ending October 31st, 1916, namely: Hardware, rubber goods, oils, grease, etc., castings, chemicals, Babbitt, solder, etc., auto sundries and supplies. Specifications and forms of tender may be obtained at the office of the city storekeeper, City Yards, corner Ross avenue and Tecumseh street.

Toronto, Ont.—Tenders for extension to sub-station building at Edwin and Ruskin avenues, addressed to the secretary of the Toronto Electric Commissioners, will be received until April 19, 1916. Separate tenders will be received for and should be marked as follows: Structural steel work; roofing and waterproofing; plumbing; painting and glazing; excavating masonry work. Specifications and forms of tenders may be obtained and plans consulted at Engineering Office, corner Duncan and Nelson streets.

Personal

David Alexander McIlroy, manager of the Hamilton Steel Construction Co., died at Hamilton, Ont., on April 9, aged 35.

Mark Workman, president of the Dominion Steel Corporation, has returned to Montreal after a ten days' inspection of the company's plant at Sidney, N.S.

Major William Henry Childs has resigned his position as assistant manager of the Hamilton Hydro-Electric Commission and joined the 173rd Highland Battalion. Major Childs served in the Boer war.

Allan Jenkins, who was second engineer on the freighter Empress of Fort William, which was sunk on February 26 in the English Channel by a German torpedo or mine, has arrived home at Orillia, Ont.

W. H. Robinson, of Granby, Que., was elected president of the Canadian Consolidated Rubber Co., at the annual meeting of shareholders held in Montreal on April 4, thus filling the vacancy left by the death of J. H. McKechnie.

Conrad F. Just, former Canadian trade commissioner at Hamburg, from which city he escaped with difficulty after the war broke out, is on the eve of departure from London to Russia, to take up similar duties at Petrograd. The possibilities for Canadian trade with Russia now and after the war will be thoroughly investigated by Mr. Just.

Trade Gossip

The Mueller Mfg. Co., of Sarnia, Ont., have been awarded a contract for waterworks supplies by the Town Council of Wallaceburg, Ont.

Fort William, Ont.—The Canada Car & Foundry Co., propose to remove their car plant from here and ship it to Vladivostock. The city council are strongly opposed to the arrangement.

The Hayes Wheel Co., of Chatham, Ont., which was recently incorporated, has taken over the Chapman wheel works at Chatham, and machinery will be installed for making automobile wheels.

W. W. Wells, 368 Victoria Street, Toronto, has supplied the Russell Motor Co., Toronto, with a 1,500 amp. motor-generator set for their plating department. This machine is equipped with a 16 h.p. motor, and can be run as either a two-wire or three-wire machine.

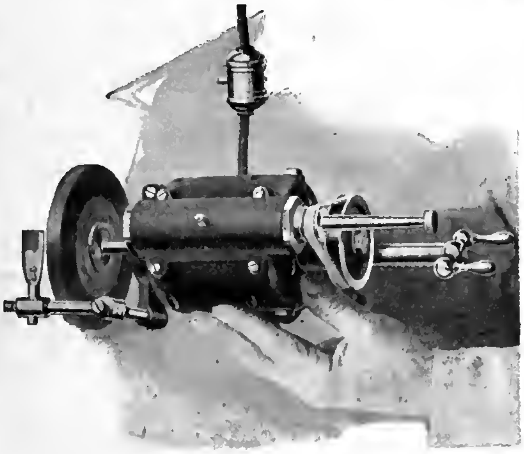
American Zinc.—The annual statement of the American Zinc, Lead and Smelting Co. of New York for the year ending December 31st last, shows net profits of $5,293,878, equal to 27.41 on the 193,120 shares outstanding, and an increase of $5,216,186 on the previous year. Reserve appropriations took $2,-642,378, an increase of $2,630,378 on 1914, leaving a surplus of $2,651,501, an increase of $2,585,809.

Record Price for Ferromanganese.—It was reported in Pittsburgh, Pa., recently that a carload of ferromanganese ,a steel alloy, was sold to a steel manufacturer of this district in the basis of $1,000 a ton, a record price. Before the war manganese was selling at $38 a ton. Another high price for steel material was recorded in the sale here of 2,000 tons of forging billets on the basis of $85 a ton Pittsburgh, a jump of $25 a ton from the last reported sale.

Fort William, Ont.—When the new elevators projected are completed and running, Fort William and Port Arthur will be only a few thousand bushels behind Chicago in elevator storage capacity. Chicago to-day is stated to have within her harbor borders, elevators that have a capacity of about 51,000,000 bushels. When the three big elevators here are running, the capacity will be increased by 5,500,000 bushels for the both harbors, or a total of approximately 50,000,000 bushels.

International Engineering Co.—International Engineering Co., of Amherst, N.S., which has been engaged in the manufacturing of munitions recently, reports profits of $77,778 for 1915. After allowing $34,492 for depreciation, writing off $3,625 on organization expenses,

Aikenhead's DUMORE GRINDER



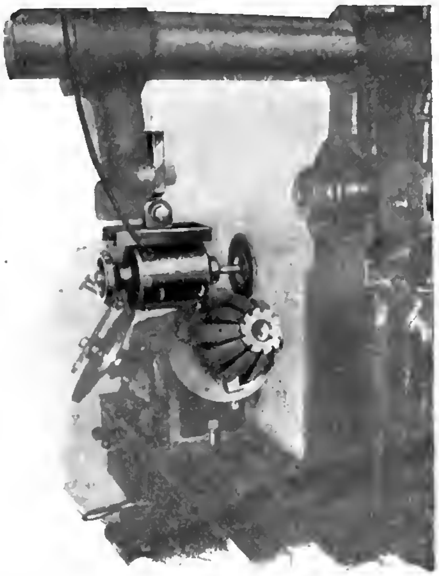
The DUMORE Portable Grinder. The only small grinder giving wheels the correct surface speed. Speed, 30,000 R. P. M.

IF you put a DUMORE Portable Grinder to work in your shop, you will quickly see a notable shrinkage in your grinding costs.

WHY?

It is portable—weighs but 17 pounds—easily carried from one job to another.

The DUMORE will do more and better work than the ordinary grinder. It saves time — and time means money.

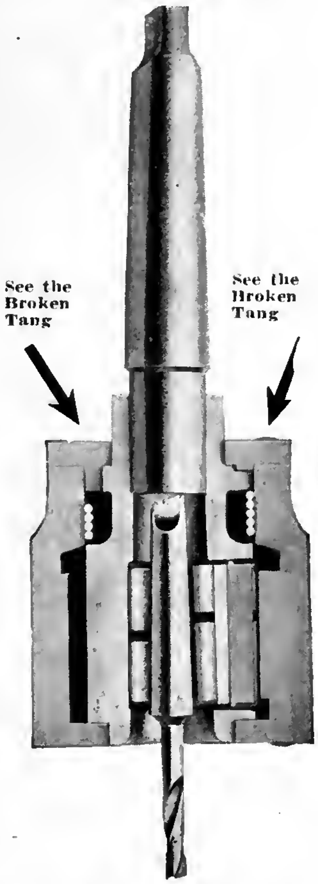


A rapid, practical way of grinding special milling cutters.

Aikenhead Hardware Limited

17, 19, 21 Temperance Street

TORONTO - - - CANADA



Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off —DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1¼"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops.

The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

CANADIAN DEALERS:

Aikenhead Hdw. Co., Toronto, Ont., Canada
Williams & Wilson, Ltd., Montreal, Quebec, Canada

Wahlstrom Tool Company

350 Carroll Street Brooklyn, N.Y.

and paying $30,000 bond interest, the company had a net balance of $9,660 to carry forward. This reduced the debit in profit and loss account to $64,437. Orders on hand at the end of 1915 were $660,000.

Manitoba Steel Foundries.—With regard to statement which appeared recently in Canadian Machinery in connection with the Manitoba Steel Foundries, Ltd., and the Manitoba Rolling Mills, both of Winnipeg. We are advised that the Manitoba Rolling Mills will be interested in the Manitoba Steel Foundries and that the Steel Foundries' plant will be built alongside of the Rolling Mills. Only part of the Steel Foundries' products will be taken by the Rolling Mills, which concern is not the parent company of the Manitoba Steel Foundries as was originally stated.

Steel Rails May Advance.—What will mark a historic event in the steel trade in the United States is an advance in the prices of steel rails, which is confidently expected in trade circles to take place shortly. The base price of rails has stood at $28 a ton for more than 15 years, fixed at about the time the United States Steel Corporation was organized in 1901, and it has never varied. Judge Elbert H. Gary, chairman of the Corporation, has issued a statement saying that the rail-making subsidiaries of the Corporation would maintain present prices until May 1st, but would make no commitments beyond that date. Railroads lately have been breaking all precedents by placing their orders almost a year in advance.

Catalogues

Clipper Clippings for March has been distributed by the Clipper Belt Lacer Co., Grand Rapids, Mich. This number deals principally with the manufacture of canvas belts and a few notes on the Stewart-Warner Corporation plant where a number of Clipper lacers are used.

The Corbet Foundry & Machine Co., Owen Sound, Ont., have issued a catalogue dealing with the line of "Corbet" roller bearing trucks for railroads, factories, warehouses, mills, etc. The various types are illustrated and principal dimensions and prices are included for each size.

The Marvin & Casler Co., Canastota, N.Y., have issued Catalogue E, dealing with the Casler offset boring heads and boring chucks. These appliances, which can be used on lathes and milling machines, are described fully, while illustrations show the various styles of boring heads and the method of mounting for various classes of work. The cata-

logue also includes specifications and prices for the boring heads, boring bars, cutters and tools.

Book Reviews

Heaton's Annual.—The twelfth edition of Heaton's Annual published by Heaton's Agency, Toronto, has just appeared. There has this year been developed a section aptly entitled "Where to Find It." This is practically an index to the more important contents of the Dominion and Provincial Government Reports and Standard Publications relating to Canada. Every business man some time in the year says to himself: "Where can I find it?" and often spends days to find out. On the other hand, the Dominion and Provincial Governments annually spend hundreds of thousands of dollars in burying information alive in books and pamphlets, of which the general public never hear. Indeed very few people know of the valuable and interesting information which can be had for the asking. By referring to this section, the reader can at once put his finger upon the information which he wants and find the publications which contain it and the department to whom application must be made. As in previous years, the Annual contains official, bank, insurance, and legal directories, postal information, cable rates, the complete Customs tariff revised to date; a shipper's guide (covering every commercial town in Canada and giving the population, railways and banks), list of registry offices for deeds, chattel mortgages, etc.; up-to-date descriptions of every town in Canada, exchange and miscellaneous tables, and a mass of valuable general information, from which cross references are given to the section "Where to Find It" for the benefit of those who want further information. It would be difficult to imagine a book which fills its mission more completely than Heaton's Annual.

FOR SALE

FOR SALE—NO. 2 UNIVERSAL MILLING machine. J. A. Harvey, 16 Pearl St., Toronto.

SIX-FOOT METAL PLANER FOR SALE—practically new. Apply A. Graham Boyd, 100 Front St. E., Toronto. (14)

TWO FOX TURRET LATHES FOR SALE—splendid condition. Ideal Foundry, 960 Gerrard St. East, Toronto. Phone Gerrard 1055. (15)

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

FORD-SMITH NO. 2 PLAIN MILLING MAchine; new; in perfect condition; ready for immediate shipment. McGregor & McIntyre, Ltd., 1139 Shaw St., Toronto. (16)

FOR SALE—FIFTEEN HUNDRED GALLON Duplex Steam Pump, used sixty days. Size twenty x twelve x sixteen stroke. Apply Fraser & Chalmers of Canada, Limited, Montreal. (12)

FOR SALE—GARAGE IN GOOD WHEAT district. Snap for a good, practical man. About forty cars in vicinity. Will sell cheap if taken at once. Address Box 74, Hanley, Sask. (13)

FOR SALE—ELECTRIC GENERATOR TO run 80 lamps, 110 volts, 300 r.p.m., including switchboard and indicator; in good condition. Richards-Wilcox Canadian Company, London, Ont.

1—C.G.E. TYPE 10—20 H.P. INDUCTION Motor—60 cycles, 220 volts, 45 amps.—1200 R.P.M., complete with Auto Starter. Pulley on Motor 12" Diam. x 10" Face. Cummer-Dowswell, Ltd., Hamilton, Ont.

IMPORTANT AUCTION

At Vancouver, B.C., of the Contracting Equipment formerly used by the

B. C. ELECTRIC RAILWAY CO. Limited

Originally Costing $250,000

On May 1st, 2nd, 3rd and 4th, 1916, By F. GRIFFIN & CO.

Including: 100 ton Baldwin Locomotive and Tender, Air Compressors, Mining Locomotives; Logging, Yarding and Stationary Engines; Hoists; Motors; Pumps; 24 Carriages and Chain Grates for Automatic Feed Stokers; 2 Lidgerwood, Panama Type, Cableways; Boilers; 40 Drills; Tunnel Bars; 25 Tons of Drill Steel; about 8000 feet of 11-in. and 16-in. Monitor Pipe and Fittings; Carload of Woodworking Machinery.

ON VIEW 25th April to date of Sale. Catalogues now ready, apply:

F. GRIFFIN & CO., Auctioneers

448 Seymour St., Vancouver, B.C., and 311 California St., San Francisco, Cal.

FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY
970 Queen St. West, Toronto (15)

FOR SALE

FOR SALE—PLANING MILL AND FACTory, doing good business. Terms $2,000.00 cash. Balance to suit buyer. Address O. Ribble, Bronte, Ont. (13)

AUTOMOBILE BUSINESS AND NEW Garage for sale. Overland agency; lots of repairing; also Overland roadster, new tires, $300.00; 10 light D.C. generator, $25.00; K.W. magneto (new), $15.00. W. E. Hawes, Otterville, Ont. (13)

FOR SALE—1 CLEVELAND ACME MAchine Co.'s 6" Cap, Single Head, Tapping Machine—back-geared, automatic feed, cone step pulleys and countershaft with two extra chucks. Particulars from Taylor-Forbes Company, Limited, Guelph, Ont. (13)

FOR SALE, AT A SACRIFICE—SAW MILL outfit, A1 condition; 50 H.P. stationary boiler. 45 H.P. "Leonard" engine, "Green" carriage, Simonds saw, edger, planer, lathmill, etc. Easy terms. Write quick. R. Parker & Sons, Uno Park, Ont. (12)

FOR SALE — COMPLETE LUMBER AND lath mill machinery, daily capacity seventy-five thousand feet, consisting of gang, single and double bandsaws, engine, boilers, etc. Fully equipped blacksmith and machine shops. Silsby fire engine, 2 streams of 2½ inch; good order. Log loader, capacity fifty thousand feet, ten hours; almost new. Exceptional manufacturing site bargains. Address The Rathbun Company, Deseronto, Ont. (18)

ELECTRODES — THE PROPRIETORS OF letters patent No. 127080, relating to "Process of manufacturing iron for use in alkaline accumulators," and No. 127081, relating to "Active masses for positive electrodes of electric elements, etc.," desire to dispose of the patents or to grant licenses to interested parties at reasonable terms, with a view to the adequate working of the patents in Canada. Inquiries to be addressed to the actual proprietors, Svenska Ackumulator Aktiebolaget Jungner, Stockholm, Sweden. (13)

SITUATIONS WANTED

MECHANICAL SUPERINTENDENT, EFFICIency engineer and master mechanic having twenty years' experience in all lines of general machine, blacksmith, carpenter and pattern shop practice, foundry work, power plant, refrigerating and electrical engineering, is open for engagement. Box 177, Canadian Machinery. (11)

CHIEF ENGINEER — 26 YEARS' EXPERIence. Factory and Central Station, Alternating and Direct Current, Gas or Steam Engines, efficiency guaranteed, own instruments, best of references. Box 181, Canadian Machinery. (12)

AS MAINTENANCE ENGINEER OF FACTory, power or lighting plant, where economy is a factor, wide experience, best of references. Box 180, Canadian Machinery. (12)

WANTED

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 613 Yonge street.

SITUATIONS VACANT

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month. Box 184, Canadian Machinery.

WANTED — MACHINISTS AND FLOOR hands on heavy and miscellaneous medium work; steady employment, modern shop, good wages. Apply, stating age and experience, P.O. Box 6, Walkerville, Ontario. (6)

WANTED

WANTED TO RENT — SMALL MACHINE shop, two or three small lathes, miller, drill, motor, furnace, usual small tools. Full particulars and terms. Box 179, Canadian Machinery. (13)

WANTED — TWO FIRST-CLASS STEEL moulders. Apply Nova Scotia Steel & Coal Company, Limited, Sydney Mines, N.S. (15)

WANTED—OUTSIDE MACHINIST TO ACT as mechanical foreman on construction work. Apply to A. B., Canadian Machinery. (15)

WANTED — YOUNG CHEMIST WHO HAS had some experience in analysis of iron, steel and other steel plant products. Apply to X. Y., Canadian Machinery. (15)

AGENTS WANTED

BRITISH HOUSE MAKING SYRINGES AND spraying machines for every possible use, need Canadian agents. The line is the most complete in the world and includes knapsack and ordinary spraying machines for fruit growers, limewashing machines for farms, factories, etc. Disinfecting machines for all purposes. Anything in the way of spraying and washing machines made to suit the market. Agents must be aggressive and ready to work the line thoroughly. Write: Spraying Machines, c/o Canadian Machinery, 143 University Avenue, Toronto.

Typical Canadian Munition Works Producing Shells

Staff Article

Ample floor space, good light, convenient transportation facilities, and provision for future adaptability to widely varying lines of engineering work are prominent features of the factory described in the following article. The thoroughness of the present arrangements accounts for the satisfactory results at present and augurs well for the success of future efforts.

AMONGST the many new factories whose existence is directly due to the widespread activity occasioned by the demand for war supplies there are many which evidence a far-sightedness on the part of the proprietors which augurs well for the future industrial career of this country. Many of the so-called mushroom concerns were by the nature of events compelled to avail themselves of just such accommodation as could be got, as it was not the policy of concerns of this nature to make any unnecessary investment in property or other possessions which were not acquired with a view to permanent possession.

Many formerly established concerns, however, were convinced that judicious expenditure in shop extensions would be ultimately profitable as well as being instantly desirable. The views which are reproduced along with this article illustrate the interior of a shell factory in this country which has produced many thousands of shells since the war commenced. The sound judgment shown in the design and construction is evidenced by the similarity of its arrangement to that of one of Britain's new arsenals several views of which we were recently enabled to publish.

The two illustrations on this page illustrate about one-sixth of the total space covered. All of that space represents an extension to a previously existing shop of considerable size in which the shell manufacture was started and continued until the continual recovery of domestic business made it necessary to find new quarters for the shell work. The addition of this new space, while relieving the old quarters and facilitating present production, affords welcome guarantee against lack of shop facilities when competition resumes its normal course and the race is to the well equipped rather than the swift.

The upper view shows part of one bay just after completion and awaiting the installation of the machines. The lower view shows the machinery installed and producing 18 pdr. high explosive shells.

Particular notice will doubtless be taken of the substantial steel framework which separates the bays. This was designed to insure maximum efficiency in the transmission of power from the numerous group drive motors, and enable its distribution to the various machines to be arranged in the most convenient manner and yet be easily adaptable to any new tools or rearrangement of machines such as might be occasioned in the future. A study of the countershaft arrangements will enable this feature to be appreciated. The countershaft battens are not bolted to the lower horizontal beams of the steel framework, but are tightened by clamp bolts so that their position can be adjusted as often as desired. The battens may be clamped on the top, bottom, or sides of these beams, which possess ample strength to resist any tendency to twist when the combined pull of numerous belts comes on.

VIEWS SHOWING SHELL FACTORY INTERIOR BEFORE AND AFTER INSTALLATION OF MACHINERY.

In common with most shell making concerns, this firm was not enabled to select its equipment as thoroughly as would have been done under ordinary conditions, but in spite of circumstances a fair degree of uniformity in size and type of machines was obtained. On the right of the lower view, page 341 can be seen seven W. P. Davis turret lathes recessing the bases to receive the base plugs, while a well balanced selection of C. M. C., Reed, and Bradford lathes are employed on body turning and thread waving at the left of the picture.

The arrangement of motors for group driving is seen here, each 30 horse-power motor taking care of a shaft half the length of the shop. By placing each motor in the next bay to its shaft, a suitable degree of inclination is given to the driving belts.

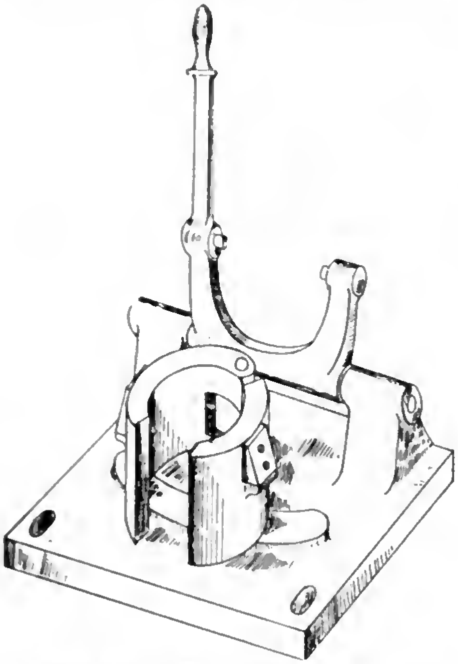
The third view shows the milling department where threads are milled in the nose and base, after which the copper band is put in position and machined, base plug screwed home, rolled, and faced off to dimension. The thread-milling machines are of the duplex type and were developed by this firm in its own shop.

After various inspections, weighings and washings, the shells pass to the paint shop, where they are lacquered and baked, afterwards being painted the regulation yellow color with a green band round the body. The last view is

taken in this department, the two operators in the foreground being engaged at a Fairbanks-Morse painting machine which revolves a number of shells simultaneously and also can be turned around while working so as to allow shells to be put on and taken off systematically.

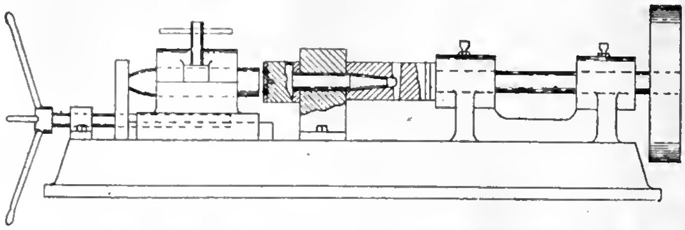
Numerous home-made devices can be noticed around most shell shops, all more or less similar, but occasionally showing a feature of more than passing interest. The rough billets in this shop are first centred in a drill press and a self-centering vise was developed which is rapid and accurate. The sketch herewith is self-explanatory. Another very effective device noticed was that used for closing up the threaded joint between the base plug and the surrounding metal.

TYPICAL VIEW OF SHELL FACTORY.



SELF-CENTERING VISE FOR HOLDING SHELL BILLETS.

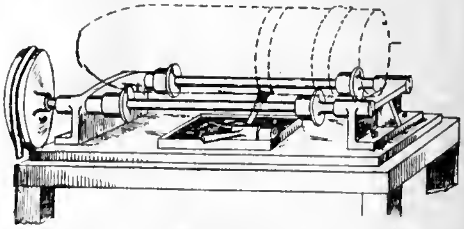
In this plant recourse was had to rolling and the simple machine shown in the accompanying sketch has proved very satisfactory for this work. The shell is placed in a hinged vise clamped together with a hinge bolt and sliding on suitable vees on the top of the bedplate. A feedscrew with lever handles is mounted on the end of the bedplate and forces the shell base against the rolling tool on the hardened face of which are three large hardened steel balls held in place by a retaining plate. The diameter of the ball race corresponds to that of the base plug, and a few seconds pressure of the shell against the balls while they are revolving at a medium speed suffices to compress the metal in the region of the joint equal to any result obtained by riveting.



MACHINE FOR ROLLING BASE PLUGS IN POSITION.

While the matter of painting the shell itself has been well taken care of by a number of machines on the market, the question of painting the band round the middle has been frequently left to the man on the job: the work involves locating the position, and width, and avoiding any spreading of the colour over the body of the shell. The last sketch shows a simple contrivance which puts the band on correctly. The shell rests on two pairs of discs carried by two shafts mounted in a simple frame work. The copper band rests on the discs at one end of the machine, which is slightly inclined so that a shoulder on ridge on the band acts as a flange against the discs and causes every shell to assume the same position. Underneath the shell a small pan with green paint is fixed and a brush of the proper width is hinged in position so that it can be swung down into the paint and then elevated against the body of the shell, painting the green band of the proper width and in the proper place. The device is mounted on a small bench with motor drive which allows of its being moved to any part of the floor to suit the progress of the work.

LACQUERING AND PAINTING SHELLS AFTER MACHINING.



DEVICE FOR PAINTING STRIPE ROUND SHELL.

The Society of Electrical Development will hold its fourth annual meeting at the executive offices in the United Engineering Societies' Building, New York, on May 9.

The Turbine Equipment Co., Ltd., Toronto, Ont., have been awarded a contract by the Board of Water Commissioners, Collingwood, Ont., to supply and instal two De Laval single stage centrifugal pumps, each having a capacity of 1,000 Imperial gallons a minute, against 165 feet head, and each direct-connected to a 75 h.p. Canadian Crocker-Wheeler motor, complete with valves, piping and venturi meter.

Limit Gauge Principles and Practical Applications--II.*

By W. H. Booth, F.G.S.

As the author aptly remarks, there exists a real lack of grasp of the purpose of limit gauges, even although more or less appreciation may be evidenced by the great bulk of operatives that interchangeability of parts of a particular mechanism being manufactured is an indispensable condition. The writer deals with the various phases of the subject in such a way as to brush aside much of the mystery surrounding limit gauges generally and as will make their service application less irksome, as well as more effective of purpose.

OBVIOUSLY, a gauge can never be accurate in itself. If a piece of work is to vary plus or minus .01 in., the gauge will have a size say, 1.99 and 2.01, but how much may the gauge vary from the nominal size? Let us suppose one-tenth of the work variation. Then, the above gauge may be accepted if at one end it measures 1.99 plus or minus .001, and at the other 2.01 plus or minus .001 — That is to say, 1.991 or 1.989, and 2.011 or 2.009.

Some mechanics prefer to make shop gauges with finer limits than inspection gauges to the extent of 25 per cent. This is a concession to the weakness already pointed out of hugging closely to one limit. It is a charge, of course, upon the limit system which represents labor inefficiency. With fully skilled men, the shop gauges need not be different from the inspector's gauges, and the system will not fail.

Screw Gauges

It is very difficult to make screw gauges which shall be correct by absolute measurement of their screw dimensions. These are the pitch of the thread, the top diameter of the thread, the bottom or core diameter, the so-called effective or mean diameter, the angle of the thread, and the top and bottom rounding. If one of these varies, all the others may vary except the pitch. Thus, if the top and bottom of the thread are of too small a radius the thread will be found to possess too wide an angle, or it will be too deep, and the core diameter will be small. By drawing a thread, the differences due to change of any dimension may be followed out. If the lead screw of a lathe is not evenly pitched, this fault will reappear in the thread it cuts, and if the end-bearing abutment of the lead screw has faces not square by the longitudinal axis of the screw there will be a slight to-and-fro motion which will reappear in a periodic variation cycle of the work done.

The only practical way to make screw gauges, except by special care, is to make them so that they pass in or on the work done, so that the work is an average fit on the check gauge. A check screw gauge is really a carefully made bolt or nut of fine finish, but it is not an accurate piece of work, but merely an average approximation. Like many engineering compromises, however, it is good enough to accomplish good work, and to maintain work up to a sufficient standard of excellence and interchangeable, except in special cases.

Essential Dimensions Factor

In getting out gauges for any piece of work, it is necessary to regard the object to be made from the point of view of its essential dimensions. These must, of course, be made to gauge. It will happen that some essential dimensions will be fixed by others, and in such a case there is no object in multiplying gauges. The parts of work to be done may sometimes be capable of very wide limits. It is not usually desirable, because of this, to mark limits which are too wide. Work that is to rough may present as many difficulties as work that is too fine. It is easy to err in the direction of supplying too many gauges, but no important dimension should be omitted. However, purely for the sake of providing a gauge, it is undesirable to make parts very closely to a given size; thus an oil hole would be figured 3-16 in. —not with a limit H.0187 L.0190—for there is no call for greater accuracy than what a nominally 3-16 drill can provide.

Work Cost Feature

The limit principle is quite wrongly applied when it involves an addition to the cost of work. Properly devised, and properly worked to, a sufficient application of the principle will cheapen work. If a diameter is wanted; say, 2 in., and there is a top limit of 2.001, the workman who insists on working accurately to 2.001 shows that he has not grasped the principles involved. If the work were wanted exactly 2 in., it would be as easy to make it exactly 2 in., as to make it 2.001. Obviously, therefore, it is waste of time and money to endeavor to work to the one limit instead of aiming to hit anywhere between limits.

I have met many men, who, when given a size 2 + .0007 have made the piece 2.00071, so as not to be too small, but what was really wanted was 2.0000, and what the workman was expected to give was 2.0002 to 2.0005. He would try to reach an exact 2.0007, whereas he had better have made it exactly 2.00 than 2.0007. The war has made many men acquainted with the limit system who did not know it before, and it has shown —what is of universal experience—that it is practically impossible to get new men to aim at the happy mean. Work has, therefore, not been much cheapened as it should have been, and as it will be when men grasp the principle involved.

Limit System Limits

Like everything else, the limit system has its limits. For extremely accurate work a man must work to a fixed single dimension gauge, or to the best he can do with a micrometer. It is in commercial work that the limit system finds its best field. By the use of the limit gauge system it is possible to have a dozen factories at work in all parts of the world making one product, such as a machine built up of many pieces. Any machine requiring repairs may be supplied with new parts, which may come from any one of the dozen factories, yet will be truly interchangeable. It is only on limit lines that such things are possible, and when an interchangeable system is properly carried out, and manufacture embodies limit gauges, it becomes possible to sell the product at a low figure, and at the same time reap large profits.

Screw Gauge a Knotty Problem

There is a prevalent idea that it is necessary for the top of the screw to make actual contact with the bottom of the nut threads. How else, for example, can a steam thread be tight? Steam would escape round the spiral space. Steam threads, however, are always put together with some kind of red lead, or iron oxide paint, and steam will not escape by the long circuitous spiral.

Now, is it humanly possible to make threads to fit on the little curves which join the slopes of the threads at the top and bottom? As a matter of personal opinion, the author sees no objection to the removal of the rounding of the top of the thread—that is, of the rounding of the threads at the larger diameter of the plug, and at the smaller diameter of the ring gauge—and would do the same with the work itself, thus eliminating two of the most difficult of the seven dimensions from the field of work. This would greatly facilitate matters, and would detract nothing from the strength of the thread. The suggestion is put forward purely as a matter of personal opinion, and as a practice the author would not hesitate to carry into effect in any commercial manufacturing undertaking.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

MANUFACTURE OF SMALL SHAFTS

By F. H. Mayoh

THE production of small shafts in quantities is a line of work frequently met with, and in most shops, the methods employed have a

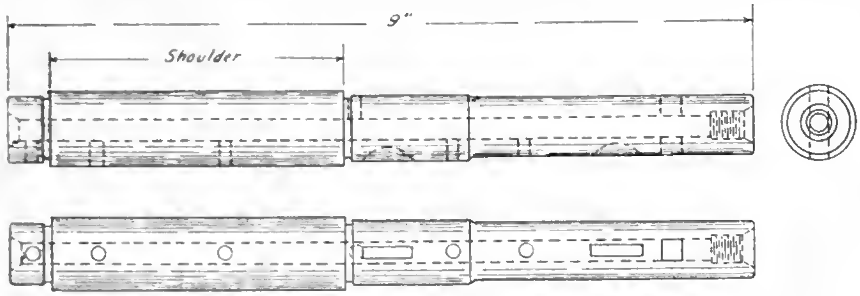


FIG. 1. SHOWING DETAILS OF WORK ON SHAFTS.

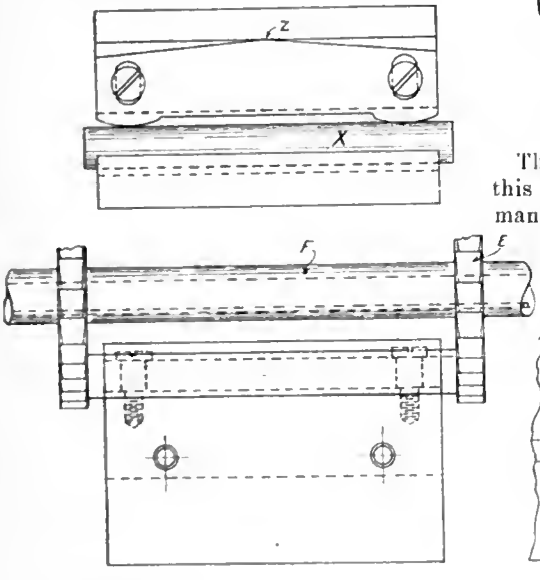
general similarity. The shaft referred to in the following article has some features rather different from the regular run of this work. It is made of steel tubing in place of being solid and this fact necessitated the making of several jigs and fixtures to enable rapid and accurate work to be produced.

Preliminary Operations

The tubing is first cut off to length, including about ⅛ in. allowance for finishing ends. The piece is then placed in a vise, see Fig. 2, and straddle-milled to an exact overall size. This is done to insure uniformity in the subsequent operations, which are based on the



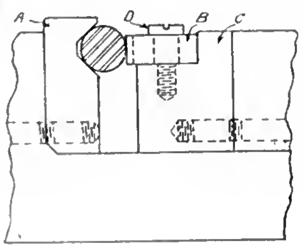


FIG. 2.

countersinks in each end of the shaft. As these countersinks are machined in relation to each end of the shaft, it follows that the ends of the shaft must be accurately machined in relation to each other.

When the ends are being milled the blank X, Fig. 2, is held securely in a vise by a V-jaw A, and equalizing jaw B. The latter consists of two pieces, viz., the jaw proper C, and the equalizer B, which rocks on the point Z, and is held in place by the screws D. The object of the equalizer is to take up any variation which may occur in the diameter of the shafts. The cuts across the ends are taken by the cutters E held on the arbor F, shown in the illustration. The work is performed on a horizontal milling machine.

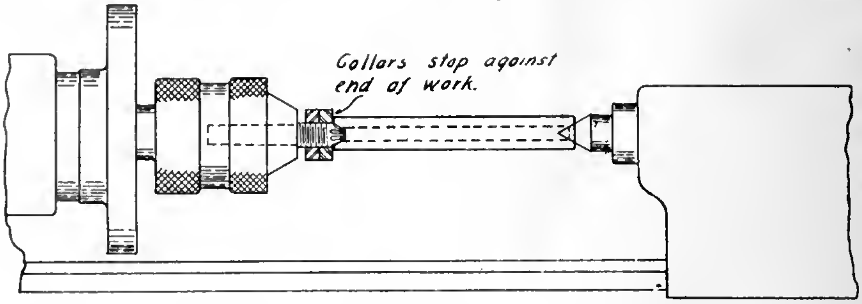

FIG. 4.

The next operation is countersinking, this being done on a speed lathe in the manner shown in Fig. 4. One end of the work is held in the tailstock centre, while the opposite end is countersunk by a special countersink reamer, with collars on it, placed in the headstock. The work is prevented from turning by gripping the shaft with the hand. To return to the construction of the countersink the collars are set to give the correct depth for countersinking; the work being countersunk until the collar comes against the end of the work on both ends of all pieces.

Fig. 3 illustrates the manner in which the work would be affected through irregularity of countersinks, the end of the shaft being subject to variation in position as shown, according to depth. As subsequent fixtures and tools are set in

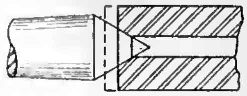

FIG. 3.

relation to the centres which support the work, the impossibility of getting accurately duplicated pieces with non-uniform countersinks will be readily seen.

Turning and Necking

For the fifth operation which is turning the four diameters no special tools were provided, and the method of turning was left to the discretion of the foreman on the lathes who used the best type of lathe available at the time, for the work in hand. The only restrictions placed upon him being grinding and squaring up the shoulder with a necking tool which is taken care of by the next operation. The work is supported between the lathe centres, the lathe being provided with a square tool box in which is held the two tools. These are accurately spaced so that in operation the desired result is obtained by merely feeding the cross slide in to the required depth.

Cutting Keyways

Following a burring operation in which the sharp corners are removed the next operation is performed, which consists of milling the two key-ways Z. Fig. 5, by holding the work X between centres and cutting first one key-way

and then the next with a Woodruff cutter; the object in milling before drilling being that it was desired to locate from the key-ways, for the drilling operations.

Tapping

It will be noticed by referring to drawing of the part Fig. 1, that a hole is tapped at one end and as the hole had to be drilled out slightly to the tapping size and counterbored slightly for starting the tap a simple jig was provided for holding the work as shown in Fig. 6. This jig consists of two vees A and B, in which the work is set. A plug C, on which the work rests, is provided, and also a screw D, with shoe E on it to hold the work in the vees. To prevent the work from turning, a pin F, is provided which fits into the key-way previously milled. As the point of the drill will follow the countersink no drill bushing is necessary. This jig is incorporated in a suitable frame G, which rests on the drill press table. The drilling operation is followed by tapping out the hole and as these operations throw a burr into the hole which would cause the shaft to run out of true were the shaft placed on centres, the next operation consists of removing this burr.

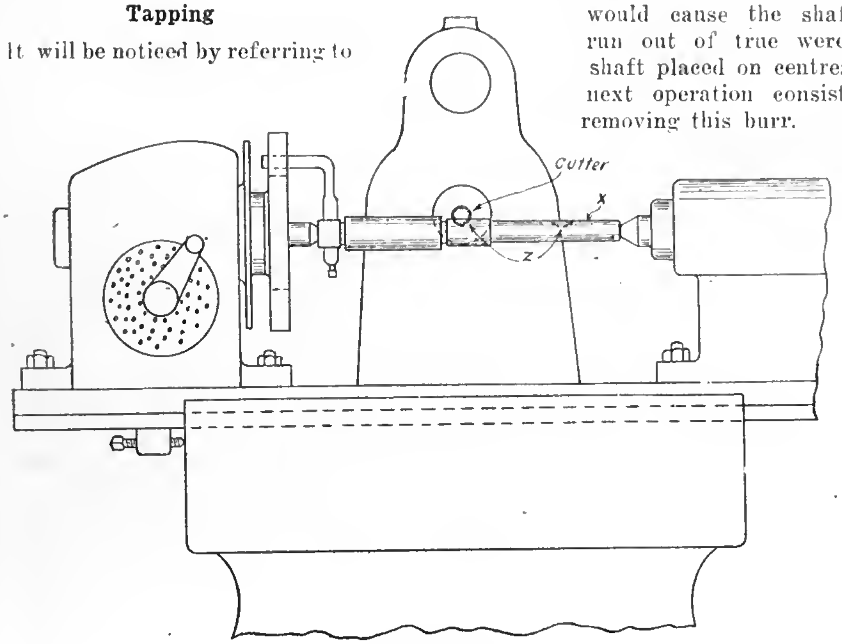

FIG. 5.

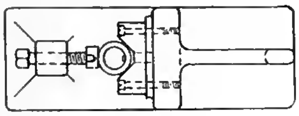

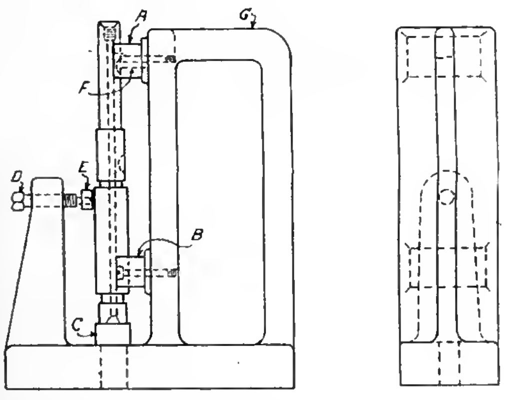

FIG. 6.

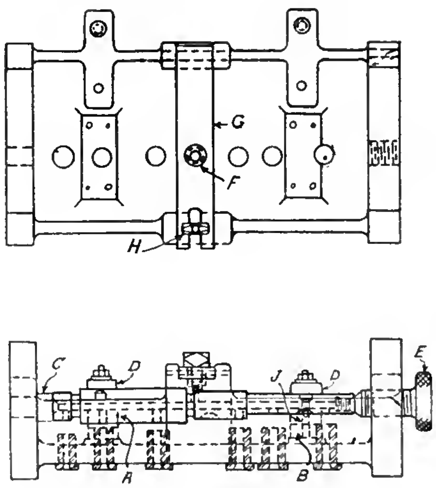
Drilling

Next in order is drilling; all the small holes being drilled in the jig shown in Fig. 7, which consists of, as in the previous jig, two vees A and B, a plug C and has in addition to these, two clamps D, for holding the work in place, and a screw E, to locate the work against the plug. For drilling the holes the jig is turned over and the various holes, including the starting hole for the square broached hole, are drilled through the bushings along the bottom while the one hole which is in the opposite side of the shaft is drilled by having the drill guided by a bushing F, in a hinged cover G, which is locked in place by the quarter turn screw H.



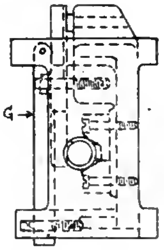


FIG. 7.

It will also be noticed that a flattened pin J, which fits in the key-way of the shaft as mentioned before, locates the work in the jig, and the holes in relation to the key-way.

Broaching

As a broaching machine was not available, an arbor press was employed for using the fixture and broach shown in Fig. 8. The shaft was supported in the two vees A and B. The broach C, was then dropped through the square bush D, the locater X, entering the hole

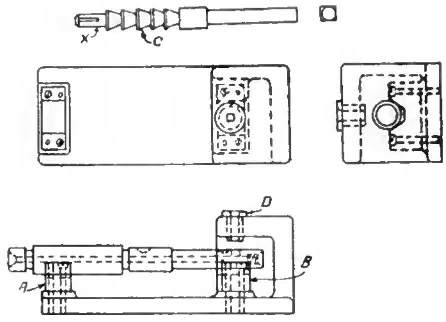

FIG. 8.

previously drilled, thus effectively locating the work in place. The fixture with the work in position, was placed beneath the ram of the arbor press and the square broach forced through.

After all the sharp corners and burrs are filed off, the work is ready for hardening, grinding and inspecting. Lastly, as the shafts are made up in lots they are greased to prevent rust and stored away to be used as desired. This method of handling insures an interchangeable manufacture of the shafts in a simple and practical manner with only a moderate outlay for special tools.

The Consolidated Mining & Smelting Co. has started construction of a plant of Trail, B.C., for the manufacture of sulphuric and hydrofluoric acid, which is expected to be ready for operation in two months. A site is also being cleared for a copper refinery, and the existing lead refinery will also probably be extended. The new plant for the manufacture of zinc is now in operation, though shipments have not yet commenced. The copper converters now in course of installation are nearing completion, and should be working shortly.

Standard Type Lathes Equipped for Large Shell Production

Staff Article

The increased output, the relatively small first cost, quick delivery and ultimate depreciation of special purpose machines, influenced their rapid adoption for small shell production. The more skilled help required for operating large machines of the type described here, with longer life and more equality in output, price and delivery have been to a great extent responsible for many machines of this type being put into use recently.

THE demand for machine tools during the earlier stages of shell manufacture was so wide-spread and urgent that shell-makers were frequently supplied with what at best were mere approximations of lathes, boring machines, etc. The experience gained on the smaller sizes of shells was, however, continually turned to account in producing the larger sizes, which, coupled also with the fact that shell construction was considerably simplified in the larger sizes, enabled ample preparation to be made by Canadian tool-builders in anticipation of large calibre shell production. The John Bertram & Sons Co., Ltd., Dundas, Ont., were particularly well fitted to produce machine tools for medium large shells, their long experience in heavy tool building placing them in a favorable position in regard to suitability of design and promptness of delivery.

Single Purpose Equipment

We illustrate herewith two lathes, built by them for handling shells up to 12 in. dia. These tools are both built from standard patterns of a special type of powerful lathe, with 12 ft. bed to be used ultimately on a particular line of manufacture. Their present equipment is of a simple but specialized nature, each lathe being adapted for performing a single operation in the least possible time, with the greatest accuracy and ease of duplication.

Figs. 1 and 2 show the front and back views of the lathe equipped for turning the body and forming the profile simultaneously. Duplex carriages are fitted, the hand wheels and levers being arranged symmetrically on the aprons as shown. The long hand-levers at the outer ends of the carriages are coupled by rods to the revolving plates which operate split nuts to engage the feed screw shaft. These plates, situated immediately below the crossfeed hand wheels are held in the engaged position by catch levers which can be thrown out when desired by hand, or disengaged automatically by adjustable stops carried on the stop rod which extends along the front of the bed.

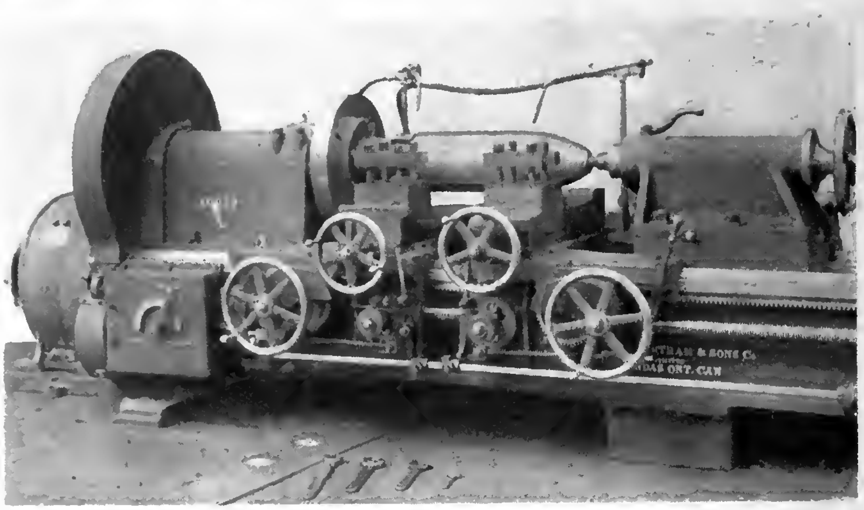

FIG. 1. TURNING THE BODY AND FORMING PROFILE OF 9.2 IN. SHELL SIMULTANEOUSLY

Profiling Mechanism

The profiling gear is of the radius link type, and is designed to operate with the tool traveling toward the right. The manner of taking the cuts and the action of the mechanism will be understood by referring to Figs. 3 and 4. Tools A and B are secured to the parallel and the radius turning carriages respectively being set half the length of the shell apart. The radius carriage is provided with a slide C at the back on which slides the bracket D, carrying the centre pin for radius link E, which in turn is connected at its forward end to the slide carrying tool B. When tool B travels slightly to the right as shown by dotted outline, it reaches the beginning of the curve; at the same time the end of bracket D comes against stop pin F, which causes the back end of link E to remain stationary while the forward end swings around and causes tool B, to travel in a circular path as shown. By this time tool A has traveled up to the starting point of tool B completing the work.

Resetting Tools

When returning the tools to the starting point, it is necessary to hold bracket D in contact with stop pin F, until link E has returned to its original position. This is done automatically and positively by the arrangement shown in Fig. 4. Three elevations of the mechanism are shown; (a) with the carriages in position commencing the cut, the rod G being kept from engaging with catch H by the cam J underneath lug I; (b) shows slide D in contact with stop pin F and rod G engaged with catch H: (c) shows the rod still engaged but the carriage has now reached the end of its travel, see position of cam J. By following the illustrations in the reverse

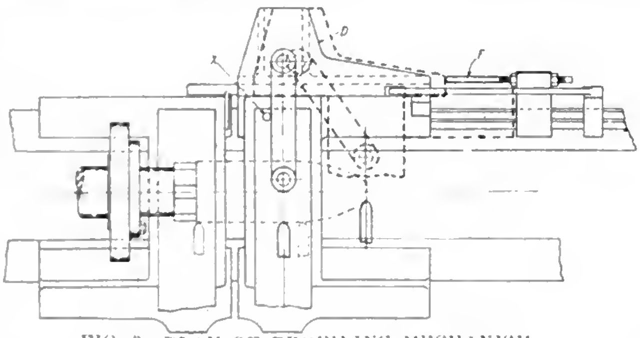

FIG. 3. PLAN OF PROFILING MECHANISM.

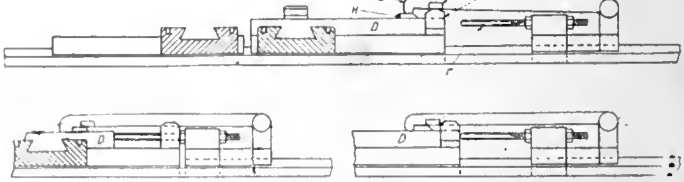

FIG. 4. SHOWING OPERATION OF LOCATING DEVICE IN FIG. 3.

order, it will be seen that bracket D is positively anchored in position until the carriage has resumed its original position in relation to it.

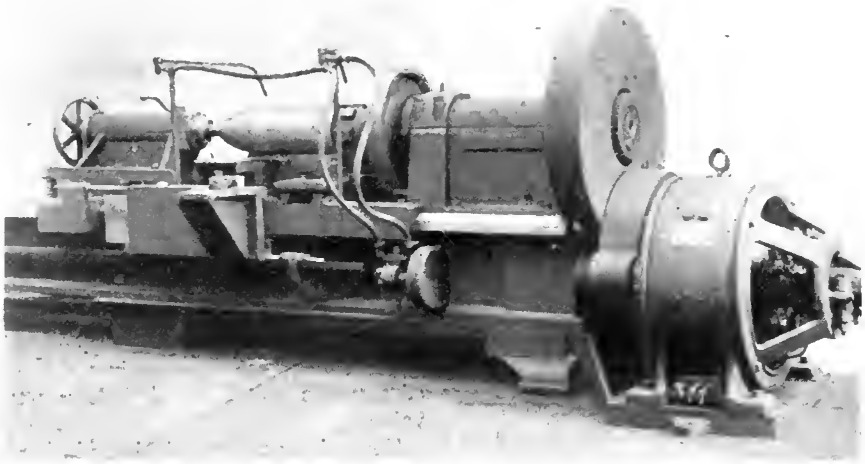

FIG. 2. REAR VIEW OF LATHE SHOWING LINK MECHANISM FOR PROFILING.

The travel of tool B to the left is limited by a stop on the back of the bed, Fig. 2, acting through bracket D and the stop X at the side of the radius link.

Driving the Shell

The shell is driven by the open end or base which is slipped over an automatic expanding arbor with a single set of three driving dogs separated by a sleeve. This sleeve is formed with a large hub having spanner notches. As the sleeve is turned backwards it causes the dogs to move across the inclined faces of three grooves, which expand the dogs against the inner surface of the shell. Any further backward movement of the shell automatically tightens the grip of the dogs. Release is obtained by slackening the sleeve forward so as to slide the jaws to the deeper part of the grooves. The nose end of shell at this stage is solid and is supported by tailstock centre.

Electric drive is provided from a 25 horse-power 2 to 1 adjustable speed motor, operating through double reduction spur gearing. The pump system is very complete with individual pipes of large capacity, a circulating drain tank being provided in the centre pedestal supporting the bed.

The machine which is shown operating on 9.2 in shells, weighs 15,000 lbs., and performs the rough turning operation in about twenty minutes.

The photographs reproduced in Figs. 5 and 6, show a lathe of the same size and pattern specially equipped for grooving and waving. In this case the feed screw is omitted, but the traversing rack is used for adjusting the carriage and the tailstock. A plan view is shown in Fig. 7, from which the details of operation will be more clearly obtained.

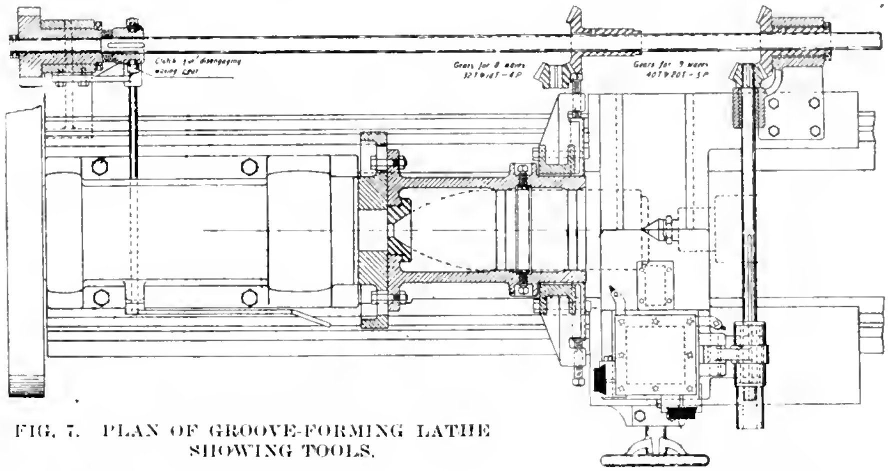

FIG. 7. PLAN OF GROOVE-FORMING LATHE SHOWING TOOLS.

The shell is held in a pot chuck bolted to the spindle face-plate, the outer end of the chuck being supported in a steady rest. The inner end of the chuck contains a bushing formed to fit the nose of the shell which is thus centred while the base of the shell is fitted with a service plug to receive the tailstock centre. When thus accurately positioned, the shell is clamped in the chuck by six set screws which tighten on a spring ring to protect the finished surface from damage. The tailstock centre is retained in use to counteract the side thrust of the tools.

The tool box is of the square revolving turret type and carries four tools for grooving, undercutting each side separately, and waving.

Waving Mechanism

Chief interest attaches to the waving mechanism. In the case of the small sizes of shells, the lathe carriages were comparatively light, and no vital objection could be found against oscillating the carriage as a whole, especially as circumstances were urgent, but the problem of imparting a rapid reciprocating motion to a heavy carriage on a lathe of this size was altogether different. The desirability of quickly altering the number of waves when desired also required consideration, hence the adoption of a shaft drive along the back of the lathe to a cross-shaft mounted on the carriage, operating the tool box only, in a separate slide parallel with the shell. This cross-shaft is grooved to engage with a feathered eccentric which allows the tool slide as a whole to be moved to or from the work as required.

The dangers attendant on the projecting end of the cross-shaft have been guarded against by the provision of a sleeve of sufficient length to keep the shaft from protruding when the tool slide is at its furthest in position. The oscillating motion is conveniently disen-

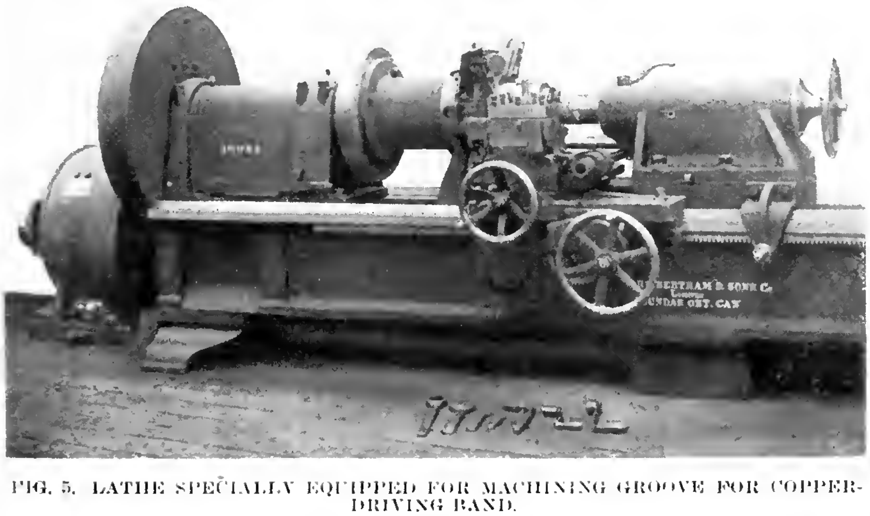

FIG. 5. LATHE SPECIALLY EQUIPPED FOR MACHINING GROOVE FOR COPPER-DRIVING BAND.

gaged by a dog clutch on the rear shaft, operated by the hand lever on the front of the headstock. By running the carriage far enough to the right hand, the bevel gear on the rear shaft can be easily removed and a different ratio substituted to cut any required number of waves.

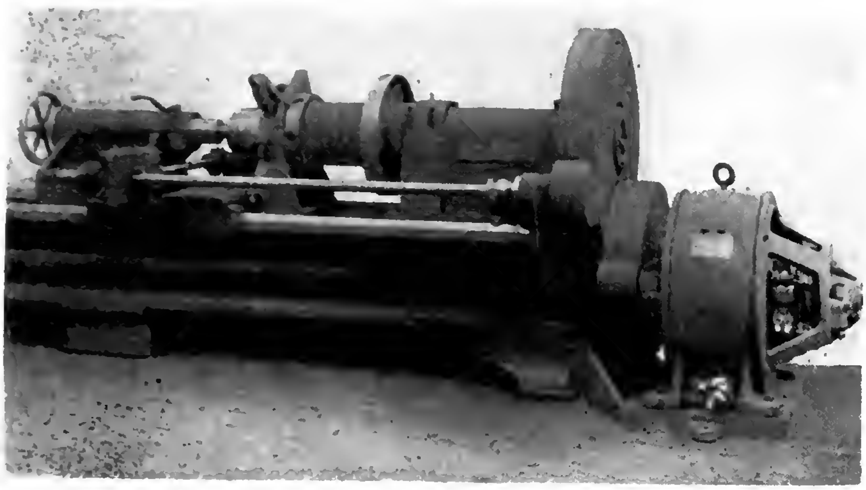

FIG. 6. REAR VIEW SHOWING SHAFT DRIVE TO WAVING MECHANISM.

OUR FUTURE METAL SUPPLIES

THAT the present feverish activity in metal production is viewed with considerable misgivings by mineralogical authorities is evidenced by an analysis of the present situation by Donald M. Liddell in the Engineering Magazine. Salient facts are stated in plain language and the anomalous features of current events in their relation to future metal supplies are elucidated in an article dealing with those metals of greatest economic value to mankind.

Tin, lead, copper and zinc are four metals which have been known to man from earliest times and with the exception of zinc, whose history as a pure metal is only 300 years, have all entered in the numerous activities of man right down through the ages, yet, as mentioned by Mr. Liddell:—"Three thousand years have gone, and tin is still so scarce that in a few months, as in 1913, the machinations of a Jewish-Chinese syndicate can send the price up by twenty per cent. The tin going on our tin cans, which is the bulk of the output, is now almost totally lost. With what the metal receptacles for food of a decade hence will be lined, is already a problem."

The destructive consumption of lead, copper and zinc is akin to that of tin. Although lead production was carried on by the Egyptians and Romans, the world's accumulated stocks of 5,000 years seem powerless to help us. "How can they, when every rain washes lead paint from the houses into the ground in a form too disseminated even to be regained; when every soldier fires away a portion of the world's stock, when almost every coffin carries a lead lining; while lead pipes or lead joints in iron pipe corrode in the ground; and when every plumber's apprentice throws away lead dross; and tea is packed in lead foil? In the meanwhile, the use of lead in storage batteries adds another possibility of loss. The sludge from these batteries will usually be thrown away when the cells are cleaned. And so the new discoveries of science help to add new methods of waste."

Recent increases in copper production have been offset by increased consumption, much of it in an irrecoverable manner—shells continue to carry their copper bands, the trolley wires of the world are subject to a startlingly rapid abrasion, all going to irrecoverable dust. "Zinc has only been available as a pure metal during the last 300 years, and 20,000,000 tons are estimated as being produced in the last forty years. Yet, as with lead, every rain washes an appreciable amount of zinc paint into the ground, cartridge cases require zinc as well as copper, and every salammoniac electric battery renders some zinc commercially non-existent. So too innumerable miles of barb wire fences, and unaccountable acres of galvanized sheets and pipes, waste zinc that iron may be preserved."

Passing over the writer's references to precious metals, his remarks regarding bituminous coal, lignite and iron ore, are limited to the statement that deposits of these minerals are estimated at from 600 to 1,200 years. "Yet this is short compared with the known duration of metal-using man . . . mineral deposits do not grow by sensible increments. And in the meanwhile, every railroad rail, car wheel and brakeshoe is wearing away, and wherever man sets his foot, iron is flaking off through insidious friction.

The two great indestructibles of our school days were matter and energy. They were the immortals. Perhaps, but there are at least degrees in energy. Lord Kelvin postulated that in every transfer or transformation of energy, a certain part was set free as thermal energy, and apparently looked forward to a universe in which all force had been uniformly distributed as thermal energy —a dead level, from which nothing could ever raise itself by its calorie bootstraps—a universe all at one temperature.

Matter likewise has its degrees. Iron-ore deposits are valuable because they are comparatively pure. An earthy crust, neatly mixed, containing in every cubic centimeter the same percentage of silica iron, gold, and tin as the present crust does in its more or less segregated deposits would be of little practical value.

Toward such a find degradation of matter man's best efforts are tending."

SEPARATING SILVER FROM PLATINUM WASTE

THE entire waste is cut into small pieces and heated to redness to destroy grease and organic substances) and then dissolved in aqua regia (3 parts hydrochloric acid, 1 part nitric acid). The platinum and all metals combined with it are thus dissolved, but the silver, as chloride, in the form of a gray, spongy powder is deposited. The solution is then drawn off, tested for the possible presence of gold, which by means of oxalic acid is precipitated as a fine, yellowish powder. The other metals remain unaffected. The platinum still present in the solution is recovered by gradual addition of salammoniac, as a yellowish gray powder. These different precipitates are washed out with warm water dried, and with the aid of suitable fluxes transformed into the metallic condition.

Platinum precipitates must, however, first be purified, and for this purpose must be first heated to redness. Then any steel or iron fragments present are extracted by means of a reagent, the remainder immersed in concentrated sulphuric acid and heated with it as long as any action of the sulphuric acid is noticeable. The remaining powder is then pure platinum.

Hot sulphuric acid dissolves silver without affecting the platinum. The fluid employed for the separation of the platinum is then diluted with an equal quanitity of water and the silver precipitated therefrom by means of saturated solution of common salt, the salt solution being slowly added until no more separation is apparent. The fluid is then carefully drawn off (filtered off), the residue washed out in warm water, dried and with some soda to act as a flux, is melted down into pure silver.

THE FOUNDRY AND THE WAR

By R.C.G.

DURING this busy season when all those employed in the mechanical arts and industrials are engaged in turning out shells, cartridges or something for the Imperial Government, very little is being said about the part foundries are playing in this great work which is being rushed to the limit. A large concern, employing at the present moment, however, only 16 molders was called upon to make and deliver two 300 ton hydraulic shell forging presses for drawing 18 pounder shrapnel shells. The total weight assembled was a little over 30 tons and there was to be no delay in shipment.

Nature of Equipment

The foundry was equipped with overhead travelling crane, 72 in. and 54 in. diameter cupolas and every modern convenience for general work but quite unsuited for heavy hydraulic castings. On account of a deficiency in the required equipment for flanks and molders it was only possible to make one at a time of the 17,000 lb. castings of which there were 2 required which left a total of 54,800 lbs. of iron to be melted for the other special castings of which there were 2 of 10,500 lbs. top tables 2 of 6,400 lbs. rams 26 in. diam,; 2 of 1100 lbs. rams 10½ in. diam.; 2 of 900 lbs. rams 8½ in. diam., but an addition there was the regular work which amounted to some 15 tons. This tonnage would take too long to melt in the small cupola, consequently the large one had to be used.

The 8½ ton table required three hours to feed and the 72 in. cupola melted 18-20 tons per hour which would make it necessary to have the molders put up enough work to total at least 125,000 lbs. which was done in 2½ days of 10 hours each. Not in itself such a bad performance when it is remembered that only 16 men were used.

Drying a Large Mold

The core ovens were 60 inches wide while the platen to be made was 92 inches in diameter, without the flask, consequently a dry sand mould could not be made. Fortunately we had a turntable flask the drag of which was about 12 inches deep and the cope 11 inches. A wooden ring was built up out of 3 in. pine segments and nailed together forming a drag 12 in. deep into which the turntable drag was set the two parts being rammed up as one. Two molders with air rammers and one helper rammed and then swept up the job finishing it and setting cores by means of a spider. The cope was rammed upon a board, nailed up and dried with the drag the following day by supporting it on trestles and building a fire underneath. Care was taken to see that the flames were kept low and the heat distributed as uniformly as possible.

While it was realised that such a weighty chunk as this should be made in a dry sand mold, our core ovens being so small necessitated skin drying, which was done by employing a mixture of 9-1 flour and sand wetted with clay wash. This was placed for a depth of 1½ inches on the outside of the mold and after blacking had been sprayed over and brushed with glutine which is a core binder composed of resinous compounds which are the by-product of the wood pulp industry, and a proportion of sour beer. The other cores and in particular the small tee ones were made of a mixture containing one part of oil to thirty parts sand. It was found that all other core mixtures were unsuited for this class of work as they were incapable of withstanding the heat without casting the cores to bake or fuse. With this mixture 45 minutes sufficed to clear the burned cores, rods, nails etc., from the slot. In setting the cores they were placed when just hard enough to handle as the subsequent skin drying which was done with steel plates and coke in about four hours gave off enough heat to dry the cores.

The pouring gates dropped iron straight down to plates nailed on the bottom of mold, so it was necessary to cut small gates in the webs of the cores to let iron in on both sides of the cores, which prevented the possibility of iron breaking core, due to the head of metal. Great care was exercised in making this skin dried mold to guard against the deep walls, cope, etc., from giving trouble due to lack of nails and gaggers which were used freely. In drying a slow uniform heat was used and a moderate temperature to prevent the flour burning out and causing the walls to crumble.

The 5 ton castings were straight dry sand work as were the 10½ in. and 8½ in. rams straight green sand, while the 26 in. rams were made with a ring pattern about 24 in. long; the mould being cheeked up and the pattern drawn as the work progressed. All cores were made with sweeps which effected a great saving in time, labor, and expense. The iron mixture used contained 30 per cent. of steel, and from the following figures it will be seen that the results were quite satisfactory.

	Sample No. 1	Sample No. 2
Silicon, per cent.	1.38	1.48
Manganese, per cent.	.55	.50
Sulphur, per cent.	.127	.142
Phosphorous, per cent.	.454	.415
Combined carbon, per cent.	.76	.70
Graphitic carbon, per cent.	2.19	2.85
Total carbon, per cent.	2.95	3.55
Chill depth, inches	¼	⅜
Tensile strength, pounds per square inch	32,850	32,700

Mixture of Iron

A 4 in. square test piece showed very uniform metal throughout, and a 1½ in. square piece showed that the iron could be easily machined, and showed no signs of excessive hardness.

Transverse test 1¼ in. dia. on 12 in. centres.

Maximum load, pounds, 4,000 defection, inches .18.

The heavier of the smaller castings required twenty-four hours to cool before cleaning, and the 8½ ton piece required 36 hours.

An Improvised Job

Recently an order for a hydraulic accumulator 23 feet long and 13 inches diameter was received. The thickness of casting was 5 in. and a 4 in. diam. core ran down the centre for almost the whole length. There was no pit, no flanks and no core ovens for drying which would fit the work; so it was necessary to improvise as much as possible.

A red pine flask was made out of 3 in. stock leaving approximately 14 in. sand around the pattern. Some iron bars were found which would fit and four were placed in the cope and four in the drag. The cope and drag were both 24 inches deep, which would make the approximate weight of cope some 9 or 10 tons which is quite a weight for a wooden flask and the figure given does not include the weight of the timber but sand only. Iron hooks for lifting with the crane were made from 3½ in. x 1 in. steel plates forged to shape at one end.

The pouring gates were 1½ in. and the runners to castings were 2 in. x 3 in.

high (they being made high so that iron would not be carried out against and cut the core) on each side 15 in. from each end of casting. The risers were 4 in. x 3 in. and $6\frac{1}{2}$ in. diam. and as there were four they were evenly spaced from the highest point at the big end where the largest was placed.

The mold was rammed by three molders, two with air rammers, assisted by two helpers the pattern was drawn, the whole job nailed and blackened in 10 hours. This was a dry sand job the mixture being 1 barrow old molding sand; 2 barrow new moulding sand; 1 barrow old river moulding sand; 1 barrow new river moulding sand; 2 pails saw dust; $\frac{1}{4}$ bag sea coal. Wet with thick clay wash. Plates, set on bricks on the parting line of drag, supported wood and coke which dried the mold in six hours.

Construction of Core

The core was anchored with 4 $1\frac{1}{2}$ in. diameter chaplets and $4\frac{3}{4}$ in. chaplets put down through the cope and barred. The heads of all chaplets were shaped to the diameter of core to prevent or minimize chances of slipping. The diameter of the $1\frac{1}{2}$ in. chaplets while unnecessary to hold core, was increased to minimize chances of burning. These chaplets were set one yard apart or very nearly so, as this was deemed advisable on account of the very small diameter of the core, the core's great length which necessitated a fairly large vent hole thus weakening and allowing it to spring in spite of $6\frac{3}{4}$ in. diameter and four $\frac{1}{2}$ in. core rods; also the thickness of the metal.

As the mold was poured in a horizontal position from each end and had to be run cold so as not to strain the mold or burn the core (which was protected by being inserted in a pipe) a small ridge was made along the top of casting to receive any or all dirt which might accumulate. This ridge was afterwards planed off before turning. The core was made in two sections and jointed with a pipe in the vent hole. Oil sand was used in the mixture, as in cases similar to the above, it had proved its capability of withstanding the extreme heat and pressure.

It might be said that in 10 days from the time the order was placed the castings were delivered. In addition to the heavy presses which are being made there are all kinds of dies, tool holders, gauges, chilled dies and machine repairs so that I believe the foundryman as usual deserves some little credit.

WAR EXPENDITURE BY THE DOMINION

A STATEMENT of Canada's war expenditure, with the establishment, strength, organization, and distribution of the expeditionary force, has been printed for presentation to Parliament. It is a formidable memorandum of one hundred pages.

Up to March 18, according to the memorandum, 262,999 officers and men had been reckoned as having joined the expeditionary force, besides 13,000 on garrison duty in Canada, bringing the total up to 275,000. As the authorized total is now 500,000 there remains a balance of 225,000 to be raised.

The forces are divided as follows:—

Overseas, elsewhere than in England, 62,000.

Overseas, in or on passage to England, 44,000.

In Canada, 134,000.

Total effectives, 240,000.

Non-effectives (casualties, etc.). 22,000.

Total expeditionary force 262,000.

Total on garrison duty, etc., in Canada, 13,000.

Grand total, 275,000.

Required to complete total authorized, 225,000.

The expeditionary force consists of, or will presently consist of, an army corps of three divisions; a fourth division (not yet formed); a brigade of cavalry; line of communication units; units allotted to oversea garrisons, and troops in England and Canada and elsewhere than in France. Three Canadian general hospitals and three stationary hospitals are serving in the British Mediterranean expeditionary force and the 38th Canadian battalion (Ottawa) is at Bermuda, and a company of the Royal Canadian Garrison Artillery is at St. Lucia, British West Indies.

Canada's war outlays to the end of the last calendar year totalled $152,996,048.95, of which $99,819,435.40 was spent within nine months of the present fiscal year. The principal items of expenditure were $81,873,230 for pay and allowances, $7,263,099 for ocean and $3,289,589 for land transport $9,148,607 for separation allowances, $9,911,707 for clothing $4,361,509 for boots, $4,909,660 for remounts $3,423,488 to the Ross Rifle Company, $2,066,263 to the Dominion Cartridge Company, and $2,880,683 for motors conveyances.

Details of the 25,500 contracts covered by these expenditures are not given in the memorandum, but it appears from copies of orders-in- Council that special steps were taken a year ago to equip the Canadian forces for a lengthening war.

On February 3, last year, an order for twenty thousand rifles and bayonets was placed with the Ross Rifle Co. at $28 for the rifles and $5.25 for the bayonets. A further order for sixty thousand was placed on Feb. 20, deliveries to be made at the rate of ten thousand monthly. All these rifles were to be of the mark 3 pattern, the prices in the second order being the same as in the first. A memorandum from the chief of the general staff. General Gwatkin, estimated the needs in a year's time with 150,000 men enlisted at 140,000 rifles and 175 million rounds of ammunition. Assuming that the war would last longer he advised the ordering for delivery during the year of 120,000 rifles and two hundred million rounds of ammunition. On May 14, last year, authority was given for the purchase of another sixty thousand rifles of the same pattern and at the same price, on the recommendation of the same officer.

NEW EXPANDED STEEL TRUSS SECTION

THE application of the expanded metal principle to the production of trusses has been successfully accomplished by the Bates Expanded Steel Truss Co., who have published the results of tests made at the laboratory of the Illinois Steel Company.

The new truss which can be employed as a beam or column, is made from a specially rolled steel H-section, which is sheared through the web in a series of cuts close to the flange, the cuts at one flange being staggered in relation to those at the other flange. The beam is then heated and placed on an expanding machine which pulls the flanges apart causing the slotted section of the web to expand or open out into the familiar triangular spaces. Tapered trusses suitable for use as posts, columns, masts, etc., are made by expanding one end only. A load of 400 pounds without deflection, failing at 600 pounds was the original strength of an H-section tested, which, when expanded sustained a load of 1,600 pounds without deflection and failed under 3,250 lbs.

Arc Welding.—Arc welding has been experimentally used for depositing new metal on worn flanges of steel car wheels. The electrode employed was of $\frac{1}{4}$ in. diameter cold-rolled steel. The total cost of removing, welding, finishing and replacing a wheel amounted to $3.50, which is approximately the same as that of turning down, while the value of the metal that would be wasted in turning is saved. Moreover, if turned, at least $\frac{5}{8}$ in. of metal would have to be removed from the thread, reducing the life of the wheel by one-third. Wheels with welded flanges have run on an average 40,000 miles, which might be increased by using carbon electrodes and chilling the metal. The process has also been employed for restoring flat spots on wheels by depositing new metal and grinding to a true contour.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

FOUR-TOOL CARRIAGE FOR SHELL LATHES

THE photographs reproduced herewith illustrate a special lathe attachment supplied to the order of a large French shell manufacturer by the Jersey City Machine Company, 40 Cedar Street, New York City. The apparatus as illustrated is designed for machining the outside of 9-in. shell blanks, and is adapted for use on the standard Niles- Bement-Pond 36 in. triple geared lathe. Figs. 1 and 2 illustrate the carriage. Fig. 3 illustrates the driving arbor, and Fig. 5 shows the rough, intermediate and finished sizes of the shell.

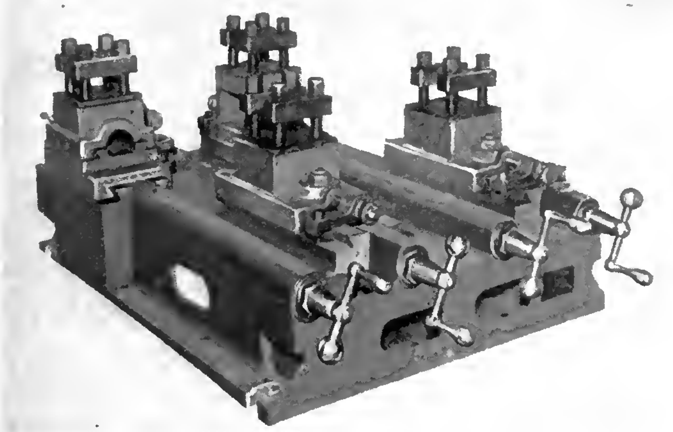

FIG. 1. OPERATING SIDE OF FOUR-POST TOOL HOLDER FOR SHELL LATHE.

Fig. 1 shows the operating side of the carriage, all of the rests being adjustable from the front, while the feed screws for Nos. 1 and 3 back cutting rests are carried through to the back, as shown in Fig. 2, for convenience in operation. With the exception of No. 1 rest, which is arranged for cutting a special taper at the mouth of the shell, all of the rests are provided with limiting stops for controlling the minimum diameter of the shell. These are in the shape of bar-clamps, which are secured to the vee-slides, and through which pass the adjusting screws carried by the rests.

An increasing thickness of wall is formed in the forging near the mouth of the shell. The object of this is to provide suitable metal so that, when nosed-in, the shell will be of proper thickness. The vertical shaft on the back of carriage, Fig. 2, carries a lever on either end, the upper lever which is half the length of the lower lever, being connected by a rod to No. 1 rest. The lower lever engages with a suitably-shaped groove carried on a bracket similar to the ordinary taper-turning attachments on lathes. As the carriage travels along the ways, the roller on the lower lever is moved towards the carriage, causing the upper lever to draw No. 1 rest away from the work during the required distance of travel, thus imparting the necessary form to the shell. Independent adjustment is provided by the small double-ended swape shown in this view.

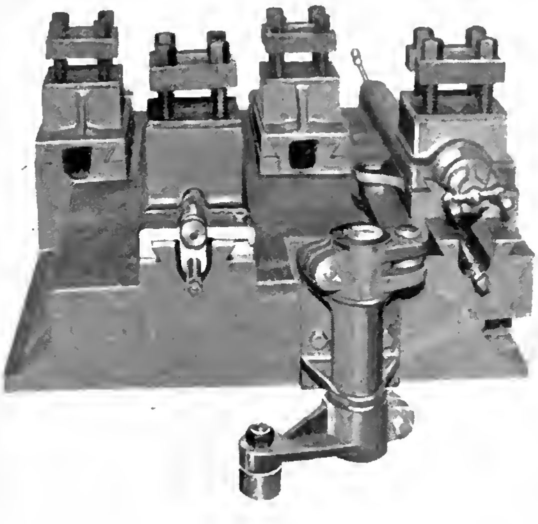

FIG. 2. REAR VIEW OF FOUR-POST TOOL HOLDER SHOWING TAPER FORMING ARRANGEMENT.

The driving arbor shown in Fig. 3 is of the automatic expanding type, and consists of a flanged stem, a slotted sleeve, and three dogs, with the necessary retaining plate, screws, etc. The stem is formed with three eccentric diameters resembling flutings on a left-hand reamer, and when assembled with the sleeve, etc., as in the lower part of the illustration, a backward motion of the sleeve on the stationary stem causes the dogs to slide up the inclined faces of the grooves, thus expanding them against the shell. The driving power increases as the sleeve is forced round, so that the heavier the cut, the firmer the grip.

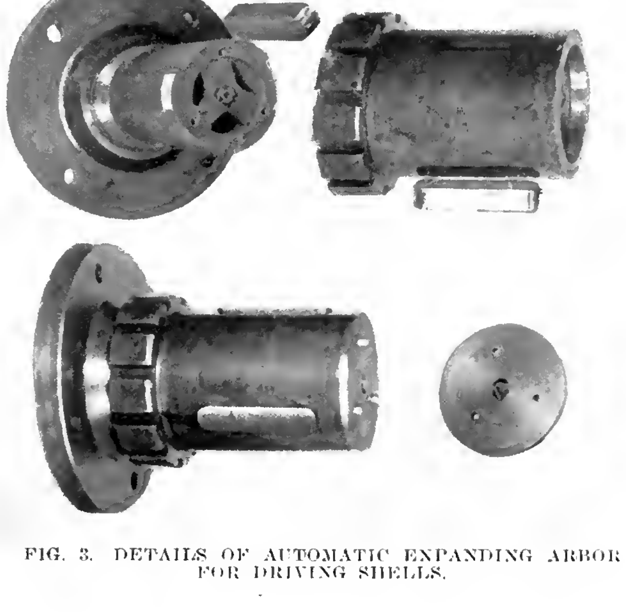

FIG. 3. DETAILS OF AUTOMATIC EXPANDING ARBOR FOR DRIVING SHELLS.

Still Less Tonnage.—When the estimates of the Department of Trade and Commerce were taken up in the House of Commons at Ottawa recently Sir George Foster frankly stated that during the coming season there was likely to be a considerably greater shortage of ocean tonnage than last year. It probably would be necessary, he said, to do many things we do not want to do and present avenues of trade may be interrupted.

ONTARIO WORKMEN'S COMPENSATION ACT

THE results of the first years operation of The Workmen's Compensation Act in Ontario, as shown in the report for 1915, tabled in the House on April 14, are satisfactory beyond all expectations and indicate the far-reaching benefits that accrue to the workmen under this legislation. One of the surprising features of the report is the fact that out of 17,033 notices of accidents that have been received up to December 31st, only 1,117 remained unadjudicated at the close of the year, and these were only awaiting the necessary reports from the workmen and the employers. Under the old Act where the workman had to sue and prove negligence, it is probable that only a small proportion of these accidents would have been dealt with and a good proportion of the judgments if in favor of the workmen, would have gone to appeal. Under the present Act, the relations between the two classes and the board, and between each other have become growingly friendly as the benefits of the Act have been revealed. The assessments for 1915 have proved more than were required in all except one of the classes, and the board state that substantial reductions in the present year and in some cases these reductions will be retroactive and apply to 1915.

Assessments Collected

The figures show that the assessments collected during 1915 amounted to $1,539,492.40, of which $1,186,221.62 was distributed or will be for accidents, and that a net balance or surplus remains of $395,026.40, a large portion of which will be remitted to the employers in lessened rates during the present year. The total number of accidents for which compensation was made 9,829. Of these cases there were 8,544 cases of temporary disability, 1,034 of permanent, and 251 deaths. The largest number of accidents occurred from falling, rolling, and flying objects, namely, 2,587; the next from machinery and parts, 2,098; third, from falls, 1,100; fourth, dangerous substances, such as electric currents, 623; moving vehicles, 270; hoisting apparatus, 208; runaways and animals, 78. Out of these, 773 cases developed blood-poisoning, of which four caused death and 11 amputation.

There were 170,711 days lost, equivalent to 569 men's labor for one year.

The amount paid by the board for injuries and disablements required on an average 150 cheques daily, amounting to $3,600.

The board in its report as to the working of the Act says: "The Act has worked smoothly and satisfactorily. The benefits of the new system of law to both workmen and employers are recognized and appreciated. Claims are expeditiously and inexpensively disposed of. Employers are immune from the expense and annoyance of litigation. The intricacies and hardships upon workmen and their families of the old doctrines of negligence, common employment and assumed risk are eliminated. The facts to be determined by the board are usually few and simple. There is no longer need for payment of legal fees either by workmen or employers."

There were 14,750 employers in Schedule 1 contributing to the Accident Fund, but not individually liable. For Schedule 2 there were 1,252 employers liable for payment of compensation fixed by the board, but not contributing to the Accident Fund. These included such bodies as railways and municipalities. There were also Crown cases, including the Timiskaming and Northern Ontario Railway and the Hydro-Electric Power Commission, who voluntarily placed themselves under the operation of the board.

The figures show that the average wage of those injured was $13.27 a week, the average age being 33 years, running between 81 years, the oldest, and 11, the youngest.

Working of Act Informal

The working of the Act is quite informal, the employer being compelled to send in a notice within three days after the accident, and forms are sent to the workman and surgeon as well. In many cases the claims are subjected to personal investigation by an officer of the board, and evidence is taken on oath.

The largest number of cases reported were from York County, 1,868; Wentworth County, in which Hamilton is located, was second, with 919; Algoma, in which the big salt works are located, was third, with 473; while Sudbury, with the copper mines, was fourth, with 468.

No payments are made except where the injury disables a man for at least seven days. This will account, of course, for the number of cases reported where no compensation could be awarded under the Act, as some were very trivial, including a mere scratch. There were 2,385 cases of one to two week's disablement, 1,625 two or three weeks; 964 three to four weeks; 585 four to five, while there was one case in which the disability extended for 41 weeks.

The general attitude of employers toward the Act is indicated by the request of a large number who are not liable under the present provisions for assessment or payment of compensation, who have expressed the wish that they should come in under the terms of the Act. In conformity with this desire legislation is now before the House.

Naturally, in an Act that increases the percentage of cases where compensation is granted for injury, the number of widows and children and other dependents benefited is one of the gratifying features. The tables show 65 widows as beneficiaries, 116 children, and of those totally or partially dependent, 35 mothers, 18 fathers and 10 others.

RAILWAY DEVELOPMENT IN CANADA

THE operating mileage of Canadian railways during the statistical year ended June 30 last, increased by 4,787 miles, although eleven months of the year were included in the war period. The mileage now stands at 35,582.

The statistical report of the Department of Railways, prepared by John Lambert Payne, Comptroller, was tabled in the House of Commons recently by Hon. J. D. Reid, Acting Minister. It shows mileage increases in all provinces except Prince Edward Island, the heaviest increase being 1,500 miles in Ontario, where the mileage is now 10,703. Approximately 1,600 miles were under construction, apart from surveys and projections, when the year ended. Including double tracks, yard tracks, sidings, etc., the total of all tracks in Canada comes to 45,885.

Railway capitalization increased by $66,990,127, bringing the total up to $1,875,810,088, including, stocks, $847,801,101; consolidated debenture stock (C.P.R.) $176,284,882; bonds, $851,724,905. There are also outstanding against lines under construction, stocks amounting to $29,257,500 and bonds of $52,224,004. Stock dividends in 1915 were $32,341,337, an increase of nineteen millions.

Lines owned and operated by the Government, and which are not capitalized, are covered in the report under a statement of cost amounting to $293,542,201.

Cash subsidies given during the year amounted to $5,059,284, of which the Dominion contributed $4,644,664, bringing the total up to $238,831,924. Total authorized guarantees by the Dominion amounted to $188,965,063 and from all sources to $409,869,165.

There was a decrease of 380,245 in the number of passengers and 14,189,151 in the tons of freight carried. The average haul was 212 miles, which is the longest in any country. Mine products led in the various classes of freight, with agricultural products second.

Gross earnings fell from $243,083,539 to $199,843,072, a decline of 17.8 per cent. due to the dividend conditions created by the war and following a sustained upward movement in traffic and revenue.

Operating expenses also decreased by $31,244,159. The number of employees was reduced by 35,000 while, though there was no reduction in the average rates of remuneration, the total salaries and wages bill declined from $111,762,972 to $90,215,727.

INDUSTRIAL RESEARCH AND THE OPEN MIND

THE question of scientific and industrial research is engaging the attention of many manufacturers in this country, who, until the matter was forcibly impressed upon them by the commercial upheaval since hostilities started, did not appraise at its full value the wonderful development of technical education by our enemy.

It is more than desirable, indeed—it is imperative that our manufacturers strengthen their impending entry into world-wide markets by availing themselves of all possible sources of information, means of research, and methods of organization. The sources of information available to us will more than likely be available to our competitors, but no matter how much exclusive information any of our manufacturers might be able to obtain, it would be but of negative value if not vigorously applied to active production and progressive advancement.

Let these words imprint themselves on the minds of those who look forward to the day when the industrial resources of this country find themselves competing on level terms with reorganized Europe for a share in the world's trade. "It appears incontrovertible that if we "are to advance or even maintain our industrial position "we must, as a nation, aim at such a development of "scientific and industrial research as will place us in a "position to expand and strengthen our industries, and to "compete successfully with the most highly organized of "our rivals." Not to-day or yesterday, but almost a year ago the foregoing sentence appeared in a British Order in Council, setting up an Advisory Council for the Organization and Development of Scientific and Industrial Research. Since then industrial history has been made in Britain, and results have been obtained which should stimulate all of our manufacturers to further and sustained effort for their common welfare.

One feature of the activity referred to calls for special reference, and that is the pooling by manufacturers in certain industries of their knowledge and experience for the common good. The time is not yet ripe for entering into detail regarding the results obtained by the Council, but two instances may be mentioned which indicate the extent of their accomplishments for the benefit of British industry. Silk manufacturers have been persuaded to sink their scruples and co-operate for the purpose of achieving important results, and a similar end has been achieved in connection with pottery manufacturers, who have decided to build an Institute of Research for the common good of the whole industry.

Occurrences such as these in two of the most conservative industries should disarm instantly those critics who would question the advisability of proceedings of a like nature in this country.

Life is too short, and our duty to each other too imperative to allow selfish motives to retard the wheel of national progress at this late hour of the day. The value lies not so much in the knowledge as in the application, and many objectors to the policy of the open mind could probably be refuted by instances in their own factories where equal opportunities for obtaining experience, information and advancement have been followed by widely varying results. As with the individual, so with the group,—given equal facilities and interchange of knowledge, the ultimate advantage will be with those who apply results to get still more results, and in getting these last results they will find themselves still further ahead of those who receive only, and receiving do not give.

A most encouraging event to the advocates of industrial research was the recent meeting of shell manufacturers in Toronto, which was for the purpose of considering ways and means for effecting various economies through the interchange of experience, standardization of methods and tools, etc. Such action will be more freely acquiesced in under present circumstances, and the benefits to be derived will most certainly be an inducement to extend such efforts in the future, if not to the industry as a whole, then at least to certain desirable sections of it.

ECONOMY IN USING METALS

THE present state of the metal market, while gladdening the hearts and fattening the purses of metal producers, ought ultimately to have a beneficial effect on the manner of consumption by large users in particular and individuals in general. In too many cases we have been apt to use whatever was most easily available and gave no thought to other materials which would have served the purpose equally as well. Much of this practice had become more habit than anything else, and only the hard fact of actual scarcity has been able to persuade people that something cheaper would be just as satisfactory.

The successive changes from brass to cast iron, and cast iron to wood in the matter of shell shipping plugs is an outstanding instance of such necessity. The results are quite as satisfactory, and any manufacturer who in his private business could effect such a saving would not be likely to return to the use of the more expensive metal, even when prices are normal.

Most people never know what they can do without till they are forced to, and not the least of the ultimate benefits of the war will be in the general economy of material, which will be practised as a result of the many more or less compulsory experiments which are being carried on at the present moment.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., April 17, 1916.—Industrial and commercial activity in all lines of industry is reflected in the many very prosperous reports recently issued by some of the large manufacturing interests throughout Canada. It is interesting, and also encouraging, to note that, in addition to the volume of business now being done in the manufacture of munitions, there is a steady increase in the domestic production of this country. The possibilities of shipbuilding in the Dominion are now under consideration, and in all probability the present year may develop into one of considerable activity in this line.

Pig Iron

Little change is apparent in the pig iron situation, the demand for steel making purposes being still very great. With the furnaces working to capacity and orders booked far in advance, all prices on pig must be considered as nominal.

Steel

Reports continue to come in, which indicates the satisfactory condition and prosperity prevailing in all branches of steel industries. No general advance is recorded in steel prices, but certain lines show slight increases. Iron bars, with advance of ½c, are now $2.40 Chicago. A slight advance of 10c a hundred is noted on New York and Philadelphia prices. Steel hoops, Pittsburg, at $3.25, show an advance of ¼c per pound. Prices at present are firm on sheets. Dealers here are active in all lines, but report no change in local quotations.

Metals

The feature of the week's market has been the extraordinary activity in copper, which continues to rise. Tin is comparatively strong, but owing to shipping conditions the situation is one of uncertainty. Spelter is not very active, but prices have increased, following the lead of copper. Lead is easier and quiet.

Copper.—The heavy purchases recently made by foreign Governments for copper supplies has resulted in a very strong market. New York is now asking the nominal prices of 29½ cents for lake, 30 cents for electrolytic, and 27¾ cents for castings. This is an advance of 1½, 2 and 1¼ cents respectively. Local conditions are moderately active, and prices here are higher. Lake, with an advance of 2 cents, is quoted at 33 cents; electrolytic up 1½, is quoted at 32½ cents, and castings are higher by 1 cent per pound, present price being 31 cents.

Tin.—With the unsteady situation prevailing in the tin market, it is difficult to define the present or early future conditions. The London market reports a drawing together of spot and future prices, the quotation of standard spot having declined £2 15s., the present price being £199 5s. On the other hand, futures have become stronger, and an advance of £2 5s. has brought the price up to £198 5s. London reports a lower price on Straits tin; with a decline of £2 15s., the present quotation is £199 5s. New York is asking the nominal figure of 53¾ cents, an advance on the week of ¼ cent per pound. Dealers here report fair business, with prices unchanged at 51 cents a pound.

Spelter.—The present condition of the spelter situation is one of comparative quiet, with prices firm, showing signs of advancing. The present strength of spelter is largely due to the recent advance in copper. London reports a very strong market, with an advance of £6 on spot and futures, quotations being £100 and £90 respectively. The New York market shows an advance of ⅝c per pound, with the nominal figure of 19.42 being asked. Local prices are unchanged at 23, with a fairly active market.

Lead.—Many foreign inquiries have been made for lead, but no record of sales has yet been made. Prices here are unchanged at 10 cents, and dealers report fair business.

Antimony.—A decline of 2 cents is reported from New York on far Eastern and American brands. Local conditions are, however, unchanged, and prices are firm at 48 cents per pound.

Aluminum.—The situation shows little change, with prices firm at 68 cents per pound.

Machine Tools and Supplies

It is encouraging to note that with the falling off in demand for shell machinery the inquiries are gradually increasing for domestic requirements, and with the advent of many new industries in this country, it is expected that the activity in the machine tool industry will continue for some time to come. The demand for small tools and general supplies continues, and to meet the constant increase in cost of production and raw materials, prices continue upward.

Old Materials

The scrap situation has been relatively affected by the recent advances in copper and spelter, prices being higher and the demand good. Old copper and brass show an average advance of 1/4c on most grades. The price on scrap zinc is now 15 1/4c, which is an advance of 1/4c. Dealers report good business in heavy melting steel, scrap and other lines of old iron and steel.

Toronto, Ont., April 18.—Industrial conditions continue to show steady improvement and the outlook generally is more favorable. With the development of trade there is more optimistic feeling in business circles and increased confidence in the future. Business is on a more stable basis as speculation has been more or less eliminated. Enterprises are being conducted on more cautious lines rendered necessary by the conditions prevailing on account of the war. The possibilities of developing the export trade of the country are now more generally realized and efforts are being made by manufacturers to establish connections in the foreign markets where Germany previous to the outbreak of the war did a considerable part of the business. If this campaign is as successful as anticipated it will help towards maintaining a favorable balance of trade after the war.

The inland freight situation is still acute although some relief is looked for as soon as navigation on the lakes is in full swing. The congestion at the terminals is delaying shipments and causing dealers and manufacturers considerable inconvenience. The ocean freight situation is no better and indications point to the shortage of tonnage becoming more acute and freight rates higher.

Steel Market

An indication of the enormous demand for steel in Great Britain is furnished by the prohibition which the British Government has recently placed on the exportation to any destination of pig iron and nearly all kinds of steel. The prohibition applies principally to rails, springs, tubes, axles, structural steel, ingots, bars and plates. Although very few of these products are made in Canada, it will probably mean that there will be a bigger demand for other materials, such as the Canadian steel companies are able to produce. The Dominion Steel Corporation is shipping large quantities of billets, wire nails, wire rods and barb wire to England and the Steel Company of Canada is also doing a big export business at very profitable prices. This export business has developed into an important feature. It has however affected the domestic market by tending to raise prices and is contributory to the present scarcity of steel. The mills are endeavoring to take care of their domestic trade, apart from munitions, but the export demand is so insistent that they have considerable difficulty in meeting the home demand.

Prices continue to advance and the market is very strong. Prices of lap-welded boiler tubes have advanced for some sizes but seamless are unchanged in the meantime. Makers report that the new demand for locomotive and boiler tubes still very heavy, being sold up for three of four months. Boiler plates have advanced and are now quoted as follows: plates 1/4 to 1/2-in. $4; heads, $4.25 and tank plates 3-16-in., $4.50. In the new quotations there is a change in the differential between the heavier and lighter plates due to the mills only rolling desirable tonnages and the heavier plates get the preference. Some mills are not taking orders for light plates.

The general situation in the sheet market is becoming stronger and the usual price of differentials between the different gauges have practically disappeared. The heaviest demand is for blue annealed sheets and some mills have their output sold up for the remainder of the year. The situation for galvanized sheets is practically unchanged but the increase in cost of spelter is tending to restrict the output of galvanized sheets.

The United States Steel Corporation has advanced the price of Bessemer and open hearth steel rails from $28 to $33 per ton effective after May 1. This is an important event in the steel trade as rails have been quoted at $28 for nearly fifteen years. The situation is generally unchanged, the demands on the mills for deliveries being as urgent as ever although new buying is lighter than for some months. The market is firm and steady there being no price changes of importance to note.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Pig Iron

The prohibition covering the export of pig iron proclaimed by the British Government will not affect this market to any extent as there has been no pig iron to speak of imported from Great Britain for many months. The situation is unchanged with quotations at the same level as last week.

Old Materials

The market is firm with few price changes of importance to note. The general trend of prices is upward particularly for coper and lead scrap. There is a good demand for copper scrap and heavy melting steel, other lines being only fairly active.

Machine Tools

There is nothing of particular importance to note with regard to machine tools. There is a fair and steady demand for tools for munition plants otherwise business is quiet. Deliveries do not show much, if any improvement, and prices have still an upward tendency due to increase in costs of raw materials and labour.

Supplies

The demand for machine shop supplies continues active and prices very firm. The only price changes of importance to note this week are in linseed oil and turpentine. The oil market is firmer and prices advanced 3c making raw oil $1 and boiled $1.03 per gallon. Turpentine declined 3c and is now quoted at 77c per gallon.

Metal Markets

The metal markets generally have reflected during the week an exceedingly strong tone, especially copper on account of heavy contracts recently placed in the States by British Government. Owing to very large tonnage involved it is more than likely that copper market will maintain considerable strength for many months. The tin market at New York is still being affected by the difficulty which is being experienced in obtaining permits to export metal from England. The spelter market while not active continues to reflect a rising tendency and a better demand Lead is quiet, with the outside market a little easier but the Trust price is unchanged. Both antimony and aluminum are unchanged and quiet. Solders are very firm but unchanged.

Copper.—The market is very strong following the large purchases recently made by the British Government. There has also been some very heavy buying in New York by domestic consumers which has also tended to strengthen the market. The copper market has never been in such a position as at present. The producers have never sold so far ahead as they are selling to-day and the demand is still pressing. Although the production of copper is materially larger than ever

copper is materially larger than ever before, the combined war and industrial demand is so strong that all the producers have been sold their output all the way from five to seven months in advance. The local market is unchanged and nominal at 30½c per pound.

Tin—The market is dull but firm. The difficulty that is being experienced in getting permits to export tin from England in quantities desired is still affecting the spot market and is tending to restrict business. Local quotations are unchanged and nominal at 58c per pound.

Spelter.—The market is quiet but has a good firm undertone. The demand especially for spot metal is improving and prices have an upward tendency. The strong copper market is influencing spelter owing to the connection between the two metals in the brass trade. Spelter is unchanged at 23c per pound.

Lead.—The "Trust" is holding the price of lead at 7.50c New York but the outside market is irregular and weaker. Producers are said to be well booked ahead which will tend to support the market. Lead is unchanged at 11c per pound.

Antimony.—The market is very dull and lacking in interest. Quotations are unchanged and nominal at 48c per pound.

Aluminum.—There is no change and the market is featureless. Aluminum is quoted at 68c per pound.

MAY BE COPPER SHORTAGE

THE purchase of 400,000,000 pounds of copper by England, together with enormous tonnages taken by domestic consumers threatens to bring about a shortage of copper for the balance of the year. Already the market is bare of June metal, several of the largest producers in the country not having a pound of this delivery available for sale, and the supply of July metal is fast approaching the same point.

The unprecedented demand from domestic consumers is unabated, the demand for August-September being particularly insistent. These months are selling at 27¾ cents, with an advance to 28 cents likely to be made at any moment. July is selling at 28 cents, but it is expected that it will soon command a premium because of the scarcity. All deliveries from September to December, inclusive, are now 27¾ cents a pound.

These record prices are not deterring consumers who are intent on covering their requirements for the balance of the year, bidding for large blocks to be delivered at the rate of one or two million pounds monthly. The 400,000,000 pounds sold to England, while constituting a new record for what is practically a single transaction, is probably far short of the aggregate tonnage taken by users of the metal in this country within the past few weeks.

The buying is lapping well over into 1917, although the larger producers are not inclined to contract heavily beyond December.

INCREASED SHIPPING FACILITIES NEEDED

NEARLY 104,000,000 bushels of Canadian grain, excluding flax, was shipped by water to United States lake ports during the fall navigation season of 1915, including 93,346,404 bushels of wheat; 3,646,644 bushels of oats and 1,836,263 bushels of barley, according to an article by R. M. Wolvin, of Winnipeg, in the recent number of the By-Water Magazine. We paid some $11,388,036 to United States railroad and shipping concerns for the privilege of delivering our grain through those channels, and according to Mr. Wolvin, will probably contribute about the same amount of money in the transportation of the remainder of the 1915 western crop to the Atlantic seaboard.

Mr. Wolvin calls for a further development of our Eastern Canadian shipping facilities, which "will turn into the coffers of Canada the ocean freights now being paid to others and we shall then retain the full price of the grain instead of so gracefully donating such a large proportion to others."

FINAL ESTIMATES FOR FISCAL YEAR

FINAL supplementary estimates for the fiscal year which closed on March 31, last, were tabled on April 12 by Sir Thomas White. They total $4,485,573 of which, $4,216,873 is chargeable to consolidated fund $40,000 to capital, and $228,664 to cover unimproved, unprovided items in the estimates for the previous fiscal year 1914-15. The various sums already granted by Parliament for the last fiscal year reached a total of $196,863,517 of which $150,734,042 was chargeable to revenue.

The supplementaries tabled to-day include the $1,550,000, paid in relief for settlers in Alberta and Saskatchewan, out of the proceeds of Governor-General's warrants; $245,700 for militia and defence; $1,500,000 for the Intercolonial Railway, and a number of small items.

TRADE COMPETITION AFTER THE WAR

THE President of the British Board of Trade has decided to appoint committees to consider the position of certain important British industries after the war, especially in relation to international competition, and to report what measures, if any, are necessary or desirable in order to safeguard that position. The following committees have accordingly been constituted:—

Iron Steel and Allied Industries

Sir Clarendon Hyde, Chairman; Mr. A. Balfour, Sir Hugh Bell, Bart., Mr. A. J. Hobson, Sir Hallowell Rogers, and Mr. Douglas Vickers.

Shipping and Shipbuilding Industries

Sir A. A. Booth, Bart., Chairman, Prof. W. S. Abell, Sir Archibald Denny, Bart., Sir Edward Hain, Captain H. B. Hooper, Mr. James Readhead, and Mr. Oswald Sanderson.

All communications relating to the above committees should be addressed to Percy Ashley, the Board of Trade, London S. W.

The consititution of a committee for textile industries will be announced shortly.

B. C. GOLD MINES PROSPER

DESPITE war the gold mining industry in British Columbia has been going ahead not only steadily but rapidly. This is shown by the report of the Dominion Assay Office of Vancouver for the fiscal year, which closed on March 31.

The total number of deposits of gold bullion received during the fiscal year ending March 31, 1916, was 1880 of the value of $2,789,350.71, an increase of 597 deposits and $684,214.59 in value over the amount of business transacted during the previous fiscal year; the total number of deposits received during the fiscal year ending March 31, 1915, being 1283, of the value of $2,105,136.12.

The assay office is evidently rendering satisfactory service to the gold mining community, and has by able and judicious management become a very important and practical help to the great mining interests in the West. The office was established in June, 1901, and the regulations governing the institution have been amended at different times to meet changing conditions, so that the Canadian gold miner would have a market for his bullion second to none on the continent.

FACING THE FUTURE

PROFESSOR RIPPER, of Sheffield University, had something to say recently anent conditions likely to prevail after the war. In the course of an address as president of the Sociological Society of the University, the doctor forecast, as most observers do, a great swing of the pendulum in the opposite direction to prosperity. On the conclusion of peace, he said, there will be a cessation to a large extent of the production of munitions, and a considerable number of men will revert to their original wages and trades. Overtime and war bonuses will cease, and there will be unemployment. Millions of men will be returning from the front to resume civil occupations, and the problem will be how to utilize those men.

In no period of our history had employers to face problems that presented more difficulties. In the past labor and capital had been opposed each to the other, but the old methods were not the best methods. The helpful services of co-operation in the production of war work ought to be retained. It was to be hoped that the old spirit of mutual distrust would pass, and that the lessons taught by the comradeship of the army and navy would be learnt in the workshops.

In future, business men would have to fight each other less and unite more. It would pay us as a commercial nation to adopt those measures. By the old methods, costs of production were enormously higher than they needed to be. The country was tired of the aggressive, domineering, blood-and-iron methods of conflict. The industrial rivalry of Germany would, added the doctor, continue after the war, and although we might prevent her gaining the freedom of our markets, such repression was merely negative. The positive thing which would determine our future and our relative position amongst the industrial nations would be our own efficiency in our men and in our methods as compared with our competitors.

GREAT BRITAIN CLOSES BIG COPPER CONTRACTS

CONSUMERS of copper in the United States were considerably disturbed recently when news came to the general trade that the British Government had closed contracts for the greatest tonnage of the metal ever sold in the country. It was learned that British agents after canvassing the copper situation carefully, had exercised options for between 200,000,000 and 300,000,000 pounds, at a price reported to be 27 cents. Expressed in tons, the order called for 100,000 tons at least, against the preceding high record purchase made last autumn of 60,000 tons. Deliveries will be made monthly during the remainder of the year according to a report in the trade, in quantities specified by the British Government as they are needed.

The Jeffrey Mfg. Co., Columbus, Ohio, have recently organized a new Contractor's Plant Department to handle the sale of a line of small rock and ore crushers, with which they will furnish their well known line of elevators, conveyers, screens, and loaders, etc. Leroy A. Kling, formerly sales manager of the road machinery department of the Wheeling Mold and Foundry Co., Wheeling, W. Va., will be in charge of the new department.

The Amalgamated Ammunition Machinery Co., Toronto, has increased its capital stock to $500,000.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Electrical

Appin, Ont.—The Council is contemplating the installation of an electric lighting system.

Glencoe, Ont.—The Town Council proposes to obtain estimates on the installation of a hydro system.

Engineering

Merritton, Ont.—The Riordon Pulp & Paper Co., will build an addition to their mill here.

Hamilton, Ont.—The Canadian Hart Wheels Ltd., will build an extension to their plant here.

Drummondville, Que. — The Aetna Chemical Co., will build a plant here for making sulphuric acid.

Niagara Falls, Ont. — The Pollard Mfg., Co., will build a foundry at an estimated cost of $10,000.

Kirkland Lake, Ont. — The Buffalo Mines are in the market for electric motors and an air compressor.

Merriton, Ont.—The Riordon Pulp & Paper Co., will lay 1,500 feet of 30 in. cast iron pipe at their plant here.

Toronto, Ont.—The Gurney Foundry Co., will erect an addition to their plant on Junction road at a cost of $2,500.

Toronto, Ont. — John Whitfield and Co., will erect machine shop and pattern storage on Front street, at a cost of $3,600.

Belleville, Ont.—The Belleville Rolling Mills are now operating the 18 in.. mill and will shortly have the 9 in., mill working.

Niagara Falls, Ont. — The Blystone Mfg. Co., of Cambridge Springs, Pa., has purchased a site here, and will commence within the next few weeks the erection of a plant for the manufacture of concrete machinery, tools, etc.

Fort William, Ont. — D. W. Davies, manager of the Canada Iron Foundries, has announced that instructions had been received from the head office of the company in Montreal to open the pipe foundry at once. This will mean that the entire plant will be running to full capacity.

Port Moody, B.C. — Boyd's Ltd., has secured a site 400 x 1100 ft., here and will erect a shipbuilding plant to cost $200,000. The plant will comprise a steel foundry, machine shop and woodworking plant. Provision will be made for launching three ships. Capt. Harry Mowatt will be manager.

Walkerville, Ont. — The Chalmers Motor Co., of Detroit, Mich., which recently obtained a Canadian charter, with a capitalization of $1,000,000, is to establish its Canadian branch plant here. A deal has been closed for the purchase of the plant of the Tate Electric Co., for that purpose.

Saskatoon, Sask.—The chalmers Motor Co., will make a large extension to their plant here. The main building will be 400 feet long, 60 feet wide and four stories high, to cost $510,000. It will have a wing, 60x50 feet, and with the recently completed service building, will add 156,000 square feet of floor space to the plant.

Municipal

Emerson, Man.—An electric light system will be installed here. The contract has been awarded.

Weyburn, Sask.—A by-law has passed to grant $35,000 for extensions to the electric light plant. E. H. Phillips is city clerk.

Sault Ste. Marie, Ont.—The City Council will shortly call for tenders for the erection of a power and pumping station, estimated to cost $7,500. Engineer, A. E. Pickering.

Brampton, Ont.—A by-law granting partial exemption to a new company who desire to establish a factory here for the manufacture of automobile tires was carried by a vote of 438 to 4.

Dundas, Ont.—A by-law will be voted on by the ratepayers on May 2 to authorize an expenditure of $55,995 on the construction of sewers and sewerage disposal works.

Wyoming, Ont. — A by-law will be voted on by the ratepayers on April 25 to authorize an expenditure of $6,500 on the construction of a new hydro-electric power and distribution plant.

Woodbridge, Ont.—A waterworks system is contemplated for this town which will include a pumping station and filtration plant. A by-law will be voted on to authorize an expenditure of $27,500.

Galt, Ont.—On April 28, two by-laws will be submitted to the ratepayers, one to raise $12,000 for the purchase of a motor fire engine and another to raise $16,000 for the installation of a fire alarm system.

Outremont, Que.—The City Council propose spending the following amounts on public works. Electric light extensions, $1,000; extension to water distributing system, $3,140; incinerator, $17,700; fire alarm systems at various schools $1,150, and an asphalt plant.

Personal

R. H. Lee has been appointed city engineer of Kamloops, B.C.

Wm. J. Chaplin, vice-president of the Welland Vale Mfg. Co., St. Catharines, Ont., died on April 11, aged 57.

J. W. Norcross, vice-president and managing director of Canada Steamship Lines, Ltd., has been elected a director of the Canadian Vickers Co. of Montreal, Que.

E. D. W. Courtice, assistant superintendent of the John Street Pumping Station, City of Toronto, has resigned his position to enter the employ of the Hare Engineering Co. as assistant engineer.

W. Chambers, formerly with the Chapman Double Ball Bearing Co., Toronto, has resigned his position as superintendent of the Cobourg Steel Co. of Cobourg, Ont., owing to ill-health, and will take an extended vacation.

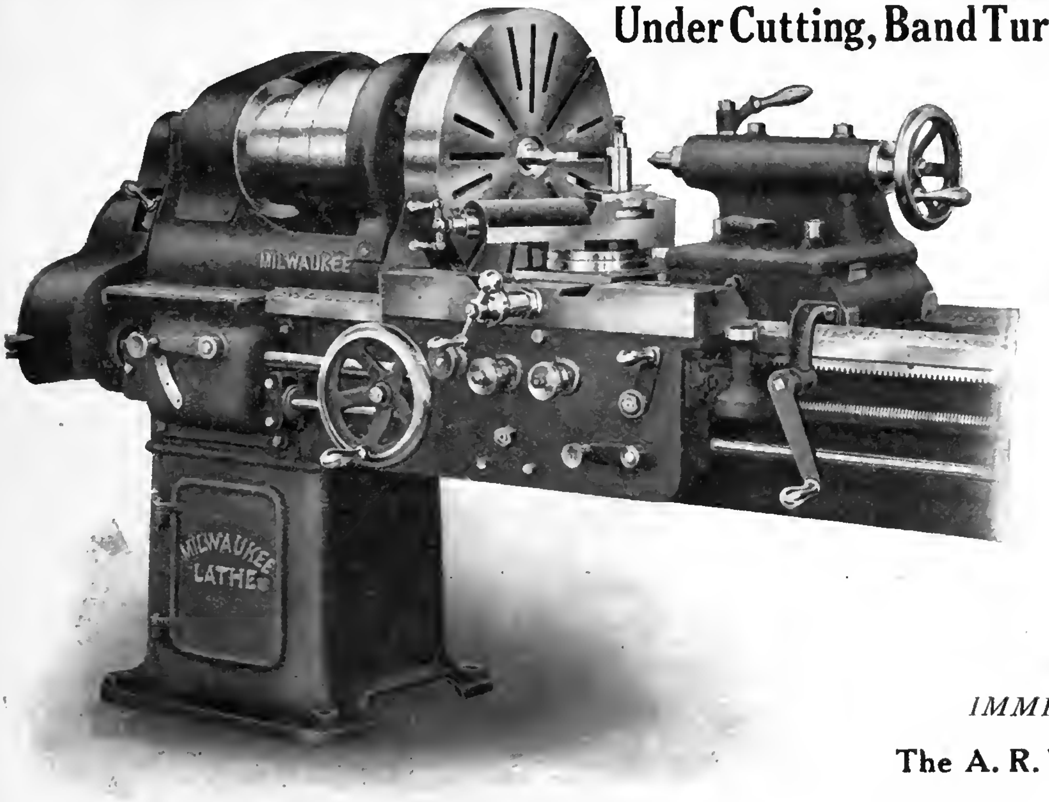
General Industrial

Quebec, Que.—The Dominion Corset Mfg. Co. will make an addition to their factory.

St. Catharines, Ont.—The Dominion Food Co. will build a factory here at an estimated cost of $20,,000.

Toronto, Ont. — The York Knitting Mills have been granted a permit to build a five-storey addition to their factory on Queen street at a cost of about $70,000.

24″ Standard Milwaukee Lathe for Finish Turning, Wave Grooving, Under Cutting, Band Turning and Rectifying



SPECIFICATIONS:

Swing over Bed.....	24½″
Swing over Carriage	15¾″
Dimensions of Front Bearing	3¾″ x 7″
Dimensions of Rear Bearing	3″ x 5″
Hole through Spindle	2 1-16″
Diameter of Spindle Nose	3½″
Pitch of Thread on Spindle	5
Diameter of Tail Spindle	2¾″
Taper Hole in Spindle Bushing.	No. 5 Morse
Cone Diameters ...	9¼″, 12⅛″, 15″
Width of Steps on Cone	4⅛″
Ratios of Back Gearing	3.45 to 1 & 12 to 1
Length of Carriage	30″
Width of Bridge	9½″
Pitch of Lead Screw	4
Cut Threads from	1 to 16
Size of Turning Tool	¾″ x 1⅜″
Depth of Bed	15″
Width of Bed	20″
Length of Tail Stock on Bed	17″
10′ Bed takes between Centers, with Tail Stock even with end of Bed	5′ 6″
Countershaft Pulleys	16″ x 6″
Countershaft should run ...	150
Net Weight with 10′ Bed..	5,600 lbs.

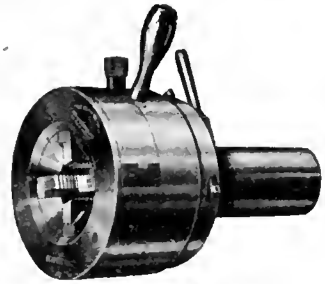
The A. R. Williams Machinery Co. Limited

TORONTO CANADA

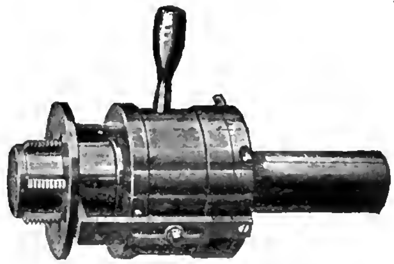
WHO KNOWS A BETTER?

"Our real reason for using Geometric Tools is the service they give—and we use them exclusively."

So says a Shop Foreman. He particularly mentioned a job, then in hand, of threading a piece 3¾ in. diameter, 11½ threads per inch, to shoulder. Between 400 and 450 such pieces were threaded daily. Each threaded piece an exact duplicate—correct in every particular.



Geometric Self-opening and Adjustable Screw-cutting Die Head.



Geometric Adjustable Collapsing Tap.

Whether it is an outside thread or an inside thread, of whatever diameter, length, pitch or form, a Geometric Screw-cutting tool will produce it. Whatever the make of your Screw Machine, a Geometric will fit it.

Let us know the class of thread-cutting that you have to do, and we will send booklet describing the type of tool best suited to it

THE GEOMETRIC TOOL CO., NEW HAVEN, CONN.

CANADIAN AGENTS:

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

Trade Gossip

The Garlock Machinery Co. have moved their office from 197 Wellesley Street to a more central location at 32 Front Street West, Toronto.

The Canada Steamship Lines are negotiating with the St Lawrence & Chicago Navigation Co., with a view to amalgamation. Details relating to the deal are being considered.

The Hare Engineering Co., Ltd., Toronto, Ont., have recently received a contract to instal their Fulton water-cooled mechanical stokers in the new plant being built by the York Knitting Mills, Ltd., of Toronto.

Francis Hawkin & Co., of Montreal have been awarded a contract for sluice gates and operating stands for a filter by the city of Chatham, Ont. The apparatus will be supplied by the Chapman Valve Mfg., Co., Indian Orchard, Mass.

Tonnage Shortage Grips Montreal.—Inquiries made in London concerning a possible solution of the tonnage problem now confronting Montreal make it clear that relief from England is not to be expected, as the shortage of ships becomes more marked daily.

Quyon, Que.—The Canadian Wood Molybdenite Co., who recently started operations at a mine containing molybdenum, about four miles from here, intend putting up a mill to smelt the ore on the spot, as the amount of ore in the mine has been far greater than was anticipated before operations were commenced. Work will be commenced immediately upon the building.

Toronto Harbor Improvements.—At a conference between the Board of Control and Harbor Commissioners on April 3 a decision was reached whereby the latter will spend $500,000 in improvements. Filling will be done at Humber Bay, Queen's Wharf, Hanlan's Point, Ward's Island and the Royal Canadian Yacht Club. In addition to this, $2,000,000 will be spent in the Ashbridge's Bay industrial district.

Britain Prohibits Export of Pig Iron.—The British Government on April 14, proclaimed an absolute prohibition of the export to any destination of all kinds of steel. The prohibition on steel applies especially to the variety used by railroads and shipbuilders, including rails, sleepers, springs, wheels, axles, tubes, girders, ingots, bars, angles and rods, and of plates more than an eighth of an inch in thickness.

Fort William, Ont.—Announcement is made that the mines and blast furnaces of the Atikokan Iron Co. will be running full blast this summer. On account of the difficulty in the treatment of the ore, it was found necessary to close the plant a few years ago, but a remedy for getting rid of the sulphur in the ore has been found, and the company expects to commence work at once, having found a remedy for treating the ore

Canadian Copper Output.—The Canadian Copper Co. of Copper Cliff, Ont., produced 99,656,000 pounds of nickel copper matte in the twelve months ending December 1, 1915, according to Hon. G. Howard Ferguson's reply to a question in the Ontario Legislature from Sam Carter, South Wellington. The Mond Nickel Co. in the same period produced 35,750,000 pounds. In that year the Mond Nickel Co. paid $4,000 tax on profits under the Mining Tax Act.

To Provide Bounty on Canadian Zinc.—Sir Thomas White on April 11 gave notice of a resolution providing for the payment of a bounty of two cents per pound on zinc or spelter, produced in Canada from zinc ores mined in Canada. The bounty is to be the difference between the standard price in London and a maximum of £36 19s. 3d. per ton. No bounty is to be paid when the price of zinc or spelter is eight cents per pound, none is to be paid during the war, and in no event is there to be a bounty on zinc produced after July 31, 1917. The total amount payable under the resolution is limited to $400,000.

Munition Workers' Commission.—Judge Snider, of Hamilton, Ont., has been appointed chairman of a special Commission appointed by the Government to investigate conditions in Toronto and Hamilton munition factories. The other members of the Commission are William Inglis, of the John Inglis Co., Toronto, and John McClelland, of Montreal, vice-president of the International Association of Machinists. The intention of the Commission is to allay such unrest and improve conditions among the munition workers, so that there will be no cessation in the operations of the plants engaged in this class of work.

Canadian Timber at Port Nelson.—That some 5,570,851 feet of Canadian timber have been used in connection with work at Port Nelson, as compared with 4,559,637 feet of United States timber, was the statement made by Hon. Dr. Reid in reply to Hon. George P. Graham in the House at Ottawa on April 13. The American wood used was long leaf yellow pine, oak, hard pine and Oregon pine. That the cost of transporting freight to Port Nelson has been reduced to one-fifth what it was originally was also shown. In 1913 the average cost of freight per ton to the port was $56.65; in 1914 it had been reduced to $13.39, and now it is only $9.62, with a direct lightering charge of $2.50 per ton at Port Nelson.

Canadian Patents.—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge street, Toronto; Robert Washburn, sash lifter; Edwin J. Banfield, plug finishing machine; James A. Varley, dummy rifle and bayonet; Toronto Type Foundry Co., folding plates for folding machines; John Fox, grain pickler; Gibson Groves, fire alarm system; George Henderson, electro-magnetic signalling apparatus; Fred. Rawlings, road planer and surfacer; Gutta Percha & Rubber Co., process of moulding and vulcanizing tires; Gutta Percha & Rubber Co., tire moulding machine; Reuben A. Shaver, grain car door; Emil C. Boeckh, broom; Albert T. Hughes, protectors and non-skidding bands for wheel tires; Samuel Glover and John West, gas producer; Charles O. Bastian, electric incandescent bodies for glow lamps; Edward B. Killen, pneumatic shock absorbing devices.

Tenders

Burlington, Ont.—Tenders will be received up to Saturday, May the 13th, 1916, for two-ton combination chemical engine hose truck. Specifications on application. Jas. S. Allen, Clerk.

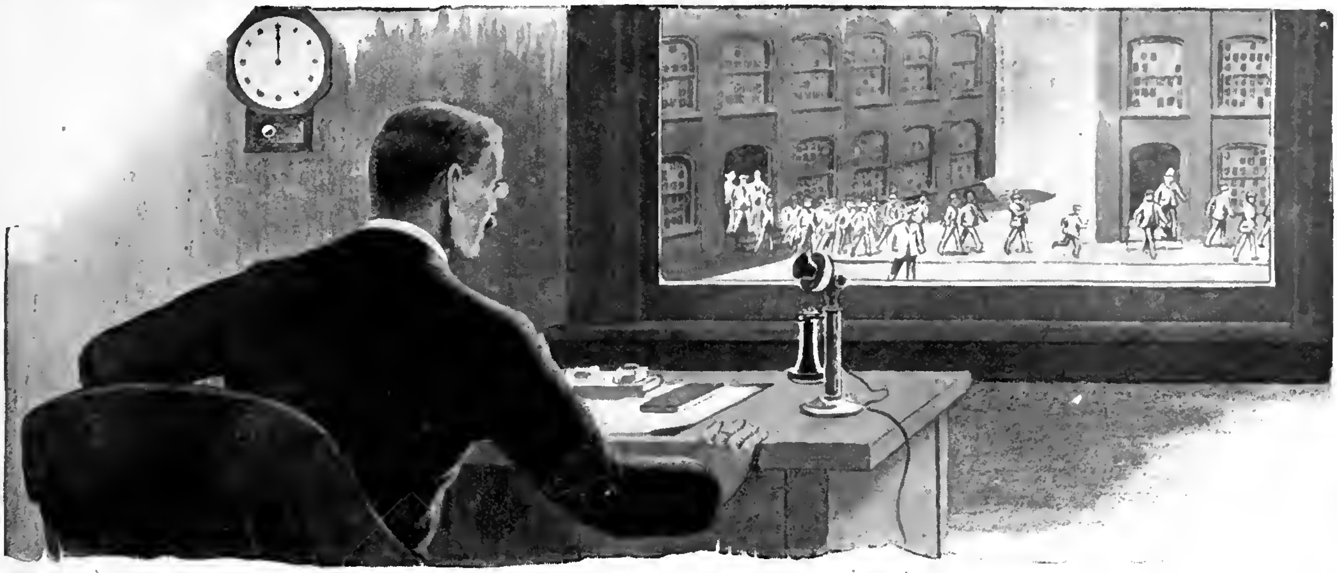
Dartmouth, N.S. — Tenders for the completion of a foundry for the Williston Steel Foundry Co., are being received by the C. Hedley Williston, 504 Robie St., Halifax, N.S. Estimated cost $16,000.

Toronto, Ont.—Tenders for steel furnishings for the new Registry Office will be received up to Tuesday, 25th April, 1916. Plans and specifications may be seen and forms of tender and all information obtained at the office of the City Architect, City Hall.

Calgary, Alta.—Tenders will be received up to Thursday, April 27th, 1916, for the supply and delivery of underground pot heads, junction boxes, switch board type, knife switches and storage battery material. Specifications at the office of the City Electrical Engineer,

Sherbrooke, Que.—Tenders will be received until April 29th, 1916, for a power pump of the capacity of four million Imperial gallons per twenty-four hours; also a vertical water wheel, flume, shaft, brackets, etc., to operate the above-mentioned pump. Specification and plan can be seen at the office of City Engineer Tremblay, Sherbrooke, P.Q.

Toronto, Ont.—Tenders will be received by the Chairman of the Board of Control, up to Tuesday, April 25, 1916, for the excavating, laying and jointing



of water pipes, valves, hydrants and special castings, for the year 1916. Specifications and tender forms for the foregoing may be obtained upon application at the office of the Water Main Extension Section, Department of Works, Room No. 320, City Hall.

Ottawa, Ont. — Tenders for metallic fittings for New Customs Offices and Examining Warehouse, Sussex street, Ottawa," will be received until Thursday, April 27, 1916. Plans, specification and forms of tender can be obtained on application to the office of Edwin Francis, Caretaker, Postoffice, London, Ont., R. L. Deschamps, Overseer of Dominion Buildings, Postoffice, Montreal; Thos. A. Hastings, Clerk of Works, Postal Station "F," Toronto, and at the Department of Public Works, Ottawa.

Victoria, B.C.—The Dominion Government is calling for tenders for the erection of buoy, store and freight sheds, trackage and drainage, etc., on the marine wharf site. Full particulars and specifications of the proposed buildings can be obtained from the local offices of the Department. All tenders must reach Ottawa by April 26 next. The plans for the proposed buildings cover a connected freight shed 147 feet by 30 feet. A commodious store shed is to be erected, and will be 108 feet by 36 feet. A buoy shed, measuring 80 feet by 40 feet, to which will be attached a shed 80 feet by 20 feet, for the use of carpenters, gas-buoy men and as machine shops, is also covered by the tenders.

Contracts Awarded

The Ottawa Electric Railway Co. have awarded a contract for track material to the United States Steel Products Co., Montreal.

St. Thomas, Ont.—The city council have awarded contracts for fire hose to the Dunlop Tire Co., and the Goodyear Tire Co.

Mount Dennis, Ont.—The school trustees have awarded the following contracts for the new Silverthorne Public school: Steel sash, Hope & Son; steel stairs, McGregor & McIntyre; heating and plumbing, George Sainsbury; galvanized iron and roof, W. E. Dillon Co.; electric wiring, W. Moon & Co.

North Vancouver, B.C.—The Vancouver Creosoting Co. has let the following contracts for work in connection with its new plant at North Vancouver: Steel rods, etc., to Balfour, Guthrie & Co.; boilers, to the Vancouver Engineering Works; and a number of tanks and condensers, to the Ross & Howard Iron-works.

Building Notes

Hamilton, Ont.—The Board of Control will probably call for new tenders for the building and equipping of the new Nurses' Home for the Mountain Hospital.

Railways—Bridges

Vancouver, B.C.—The general plan, as submitted to the bridges and railways committee of the City Council for the C. N. R. station to be erected east of Main Street, on the railway property, has been tentatively approved by the committee, and its approval by the City Council been recommended. The cost of the proposed terminal will be at least $1,000,000.

Marine

Sarnia, Ont.—The whole dock of the Northern Navigation Co. in this city, about 900 feet in length, will be rebuilt. Last year part of the structure was rebuilt, but now orders have been received to put in the whole length new.

Canada Steamship Line Officers.—The commanders of the steamers of the Canada Steamship Line Niagara fleet are: Cayuga, Captain, C. J. Smith; chief engineer, A. Mains; Chippewa, Captain, William Malcolm; chief engineer, H. Parker; Corona, Captain, B. A. Bongard; chief engineer, Joseph Kennedy. Toronto-Charlotte and Montreal division: Toronto, Captain, John J. Farrell; engineer, D. J. Leslie; Steamer Kingston, Captain, E. A. Booth; chief engineer, William Chipman. Toronto and Hamilton division, Modjeska, Captain, P. Walsh; chief engineer, A. McLaren; Macassa, Captain, J. Henderson; chief engineer, E. A. Price; Turbinia, Captain, B. W. Bongard; chief engineer, William Noonan.

Wood-Working

Gore Bay, Ont.—W. E. George proposes to erect a planing mill.

Three Rivers, Que.—Anseline Dabe, of this town, is in the market for wood-working machinery.

Elmira, Ont.—Bauman & Letson will rebuild their sash and door factory which was recently destroyed by fire.

Montreal, Que. — The Miner Lumber Co., Coristine Building, is in the market for wood-working lathes.

St. John's, Que.—The furniture factory of D. H. Langlois & Co. was recently destroyed by fire. Loss, $16,000.

Refrigeration

Montreal West, Que.—The Elmhurst Dairy Co. are building a refrigeration plant.

Killarney, Man.—Mr. Stainton, manager of the Crescent Creamery Co. of Winnipeg, has completed arrangements for the erection of a creamery at this point. A $5,000 plant, including mechanical cooling machinery, will be installed to start with. Butter making only will be engaged in at first; later an ice cream business will be installed should the business warrant it. Building operations will be commenced at once.

Catalogues

The Babbitt Specialty Co., New Bedford Mass., have issued a leaflet illustrating and describing "Babbitt" adjustable sprocket rim for attaching to the wheel of any valve. A price list is included for rims and chains.

Foundry Cupolas.—Catalogue No. 118, describes and illustrates foundry cupolas made by the Whiting Foundry & Equipment Co., Harvey, Ill. The Whiting cupolas are described fully and special features of their design dealt with in detail. The illustrations show the construction and new improvements. A table of dimensions and capacities is given, and code words for the various sizes are also included. Other equipment illustrated and described include charging machines and cars, bottom door hoists, blast gauges and fire brick linings, etc.

Monetary Times Annual Statistical Review and Outlook Number, edited by Fred W. Field. Published by the Monetary Times Printing Co., Toronto, Ont. Price 50 cents. The review this year is of special interest, as it covers a period when the financial and industrial situation in Canada has been greatly affected by the war, and unforeseen circumstances have resulted in many difficult problems arising, which have had to be dealt with from time to time. The manner in which some of these problems have been handled is dealt with in a series of articles written by well-known authorities on financial and commercial matters. Other interesting subjects covering similar ground, irrespective of the war and its effects, are also dealt with in a comprehensive manner. The volume is divided into four sections, with a preliminary financial review. The sections are devoted to banking, bonds and investments, insurance, and industrial matters; the latter section including an interesting article on the Nova Scotia Steel & Coal Co. The review contains a number of interesting statistics, diagrams and illustrations.

ST. CATHARINES, ONTARIO

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge street.

SITUATIONS VACANT

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month. Box 184, Canadian Machinery.

WANTED — MACHINISTS AND FLOOR hands on heavy and miscellaneous medium work; steady employment, modern shop, good wages. Apply, stating age and experience, P.O. Box 6, Walkerville, Ontario. (6)

WANTED

WANTED — TWO FIRST-CLASS STEEL moulders. Apply Nova Scotia Steel & Coal Company, Limited, Sydney Mines, N.S. (15)

WANTED—OUTSIDE MACHINIST TO ACT as mechanical foreman on construction work. Apply to A. B., Canadian Machinery. (15)

WANTED — YOUNG CHEMIST WHO HAS had some experience in analysis of iron, steel and other steel plant products. Apply to X. Y., Canadian Machinery. (15)

WANTED—FIRST-CLASS BOILER MAN TO take charge of battery of water tube boilers, 1200 H.P., which will be increased. Should be familiar with steam engine and air compressor. Reply, giving particulars of experience and salary expected, Box 191, Canadian Machinery. (19)

PATENTS

TAKE NOTICE THAT THE STANYON Metallic Furniture Co., Limited, of the City of Toronto, Canada, duly manufactured the movable grate covered by Canadian patent No. 101997, and that the Bennett & Wright Co., Limited, of the same city, duly manufactured the hot water heater covered by Canadian patent 107120 prior to the period called for by the Patent Act, and on application to the undersigned any further orders for the two above inventions will be filled at a reasonable price. Ridout & Maybee, 59 Yonge Street, Toronto, attorneys for Anders B. Reck.

Metal Coating Processes: Their Application and Apparatus

Staff Article

Metal coating is a mechanical process as distinguished from electro-plating and dipping in molten metals which processes exert more or less of an alloying influence between the work and the coating. The processes described cause the metal to impinge so violently as to intermesh with the surface particles of the substance being coated, at a temperature and under conditions which allow of its application to non-metallic, perishable and delicate materials.

THE protection of metals from oxidation has long occupied the attention of chemists and metallurgists. Many methods and processes have been developed and utilized, with varying degrees of success, but in every instance their usefulness has been confined within certain limits: both to the metals or objects coated, and also to the coating materials.

With the exception of the higher classes of electro-plating the only two notable examples which have been extensively used in the industrial field are those of galvanized zinc and tin covered sheets; and even with the limitations imposed by lack of scientific knowledge up to this time, millions of dollars have been invested, and made, with these two metals, acting upon sheets of iron brought to the coating medium, and individually handled. However, even these processes with all their other limitations could not be successfully carried out with some metals, and no coating could be made on fabric, wood, glass, etc.

Recent Developments in Metal Coating

Probably the most recent method, and also the most promising for commercial and industrial purposes, is that of the Schoop process. For many years Dr. Max Ulrich Schoop, of France, carried on research and experimental work along

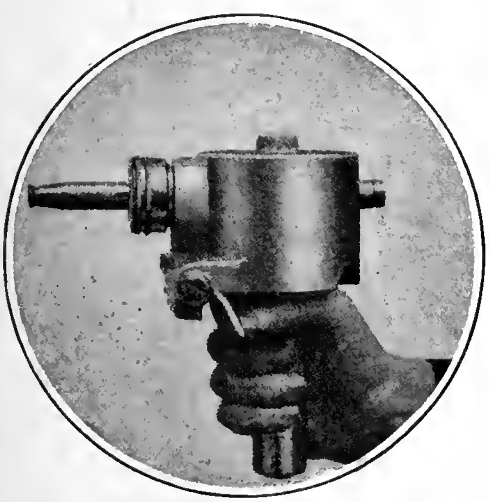

FIG. 1. METAL COATING PISTOL WITH AUTOMATIC WIRE FEED AND BLOW PIPE COMBINED.

these lines, which has recently been developed by the present holders of the process patents to such a degree that the uses to which this process can be adapted are almost innumerable.

With this latest method—in contradistinction to all other methods— it is not necessary to bring the object to be coated, to the coating medium; the process can be successfully applied under any condition. No surface of any nature whatever will be too small, nor too large, to receive a coating of almost any metal, varying in thickness from 1-1,000 of an inch to as thick as may be desired. In other words, the applications of this discovery are revolutionary in character and have evoked the wonder and admiration of the scientific and industrial world, in the possibilities opened up for their use and application.

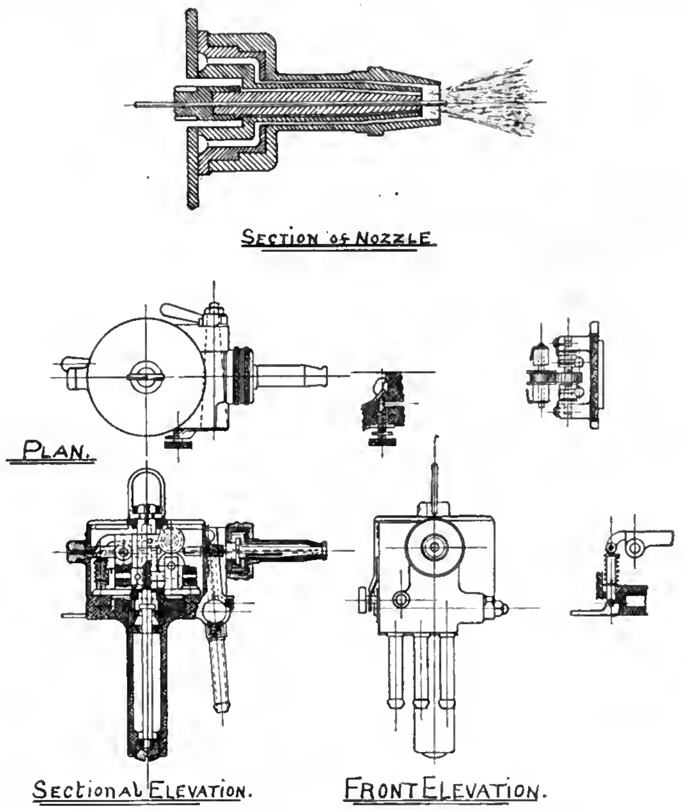

FIG. 2. DETAILS OF PISTOL CONSTRUCTION.

Light and Serviceable Equipment

The necessary equipment for this process of metal coating, is a supply of oxygen and hydrogen, and a specially constructed "pistol," shown in Fig. 1. The operation of this "pistol" will be more clearly understood by referring to Fig. 2, which illustrates the internal details of nozzle and operating mechanism. This interesting portion of the "pistol" consists of a minuiature air motor, with straightening and centering device, also a set of rolls for feeding the wire through the "pistol." These feed rolls can be operated at two different speeds, according to the nature of coating metal being used and the grade of coating desired. When the oxygen supply enters the "pistol" it divides into two channels, one leading to the nozzle, and the other into the operating motor. The sectional cuts shown in Fig. 2 are views of the most recently developed type of "pistol," used for disintegrating a wire of any metal and projecting the molten particles thereof on to a surface so that they are in intimate contact therewith.

The theory of the Schoop process, as given by the inventor is, that the gaseous medium used is much larger in volume at any moment than the drop of metal it has atomized and is carrying, and the gas is expanding so rapidly that its temperature is far lower than that of the spray. A rapid exchange of heat therefore, takes place between them which consolidates the molten particles and gives them a temperature far below the melting point. If the particles arrived in a liquid state at the base with the observed velocity of 3,000 feet per second, they would simply splash on the surface and largely rebound. As a matter of fact, they impact and inter-penetrate freely, and later bombarding particles unite with the earlier ones to form a homogeneous compact body.

"Gravitas" Method of Application

The latest development along these lines is that shown in Fig. 3 which is the "Gravitas" (trade mark) type of machine, in which the metal to be used

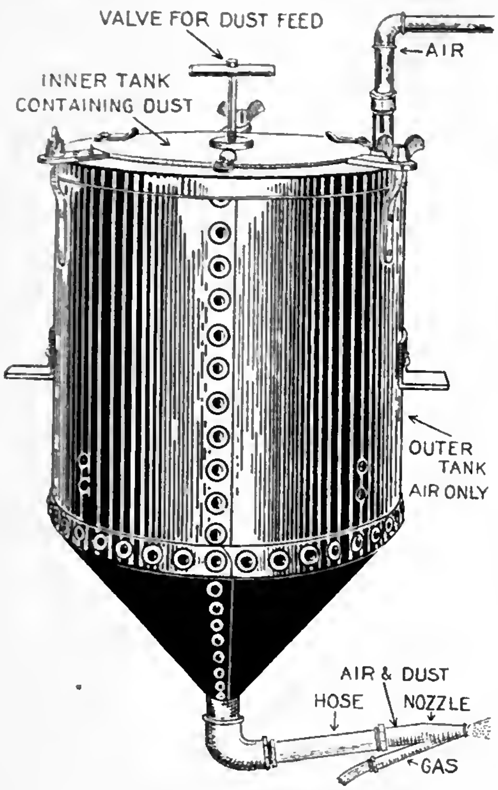

FIG. 3. DOUBLE TANK APPARATUS FOR USE WITH METALLIC DUST PROCESS.

for coating is finely pulverized before being applied. In this apparatus, the inner tank contains the metal dust, and the outer portion, the air: the supply of metal dust is regulated by the valve shown in the centre of the tank which communicates with the outlet at the base. The mixture of air, dust and gas is then ignited and applied similarly to that described above.

In all cases of metal coating it is advisable to have surfaces thoroughly cleaned before applying the spray: in fact, to insure satisfactory work it is essential that the surface be entirely free from any dirt, grease or other impurities. It may be found necessary, therefore, under certain conditions, that surfaces will require to be sand-blasted or otherwise cleaned to remove any objectionable feature that would prevent the satisfactory application of the coating material.

An interesting feature in connection with the use of this method of metal coating is noted. This is the use of the Schoop system of metalisation for imparting a metallic polish to the surface of enemy airships. The nose end of the envelope is coated for about one fifth of the ship's length, and considerable increase in speed is obtained due to the decreased skin friction between the surface and the atmosphere.

Tables 1, 2 and 3 set forth the relative cost of various coatings under different conditions. These costs, however, are based on the price of metals under normal conditions before the opening of European hostilities.

Unlimited Field

The uses of the processes are so wide that to enumerate them all would be to index all the arts and sciences. The general application for electrical purposes is unlimited, and for construction and industrial purposes this method of applying non-corroding metal will be indispensable, taking the place of the now expensive and easily destructive paints and varnishes. In fact the process can be adapted to such universal advantage that it is almost impossible to conceive the entire range; even the long sought "putting on tool," of the careless mechanic is now available.

Experimental Laboratory

Fig. 4 shows a view of the temporary laboratory in Montreal; a large variety of articles are here shown which have been coated with various metals. The operator on the left is seen spraying a 4.5 shell with a coating of zinc, while the operator on the right is coating a smaller shell, by the "Gravitas" process.

ECONOMIC CONFERENCE OF THE ALLIES AT PARIS

ON THURSDAY, April 27th, there will be opened at Paris the International Parliamentary Economic Conference of the Entente Allies for the purpose of discussing the advisability of advance agreements among the Allies concerning all legislative measures intended to regulate commercial relations between the belligerents. The subjects to be discussed will include the following:

The execution of contracts, the collection of debts, sequestration of goods and chattels, the question of patents and kindred subjects; measures of precaution against the invasion of the markets of the allies by German products upon the conclusion of peace; measures for repairing the damages of war; reduction of postal, telegraphic and telephonic rates, and the establishment of a minimum tariff in favor of the allies; agreements in regard to the international transportation of merchandise; the creation of an international patent bureau; commercial affairs of the col-

onies of the allied nations; internationalization of the law governing corporations: measures destined to reduce metallic circulation; the institution of an international clearing house; uniform principles to be embodied in laws relative to the false designation of merchandise; laws concerning failures; legislation relative to the loss or theft of securities payable to bearer.

The discussion of these questions will occupy the three days' session.

FIG. 4. VIEW IN EXPERIMENTAL LABORATORY SHOWING A VARIETY OF THE APPLICATIONS.

THE POSSIBILITIES OF SHIPBUILDING IN CANADA

A NOTABLE contribution to the literature on the possibilities of shipbuilding in Canada was made on April 19 by Col. Thomas Cantley, president of the Nova Scotia Steel & Coal Co., and vice-president of the Canadian Manufacturers' Association, at a dinner given by the Montreal Branch of the Association at the Canada Club. Col. Cantley discussed the shipbuilding problem as follows:

The Shipbuilding Problem

Marine transportation at the present time is a matter of vital interest both to Canada and the Empire. The losses of British merchant shipping tonnage during the past twenty months of this war have amounted to more than two and a quarter million tons—the losses during several months averaging over two steamers per day. We have recently lost more shipping in one week than the shipbuilding resources of Great Britain produces in three months. These losses, coupled with the transportation demands of Britain and the Allies, and the inevitable law of supply and demand, have caused freight rates and the value of ships to advance from five to fifteen times over those formerly paid. So long as the present war and the transportation problems arising out of it continue, no relief can be expected from outside sources.

On the Great Lakes Canadian shipping amounts to only a small fraction of the lake tonnage. On the ocean, Canadian ships carry less than one-tenth of the produce sent out of Canadian ports, while very large quantities of other Canadian products pass through American ports. It is estimated that, before the war, Canadians were paying over $50,000,000 yearly in ocean freights, almost all of which went into the pockets of foreign ship owners.

Overseas Trade Expansion

If we assume that there will be a very large volume of immigration to Canada after the war, doubtless a considerable proportion of this influx will settle on the land, principally in the West, and at a reasonable time thereafter there should and undoubtedly will be a very large increase in our exports of agricultural products. Of the four to five hundred thousand Canadians returning from the battle-front when the enemy is defeated, a large number, both by previous training and inclination, will expect to find employment in the various workshops of the Dominion.

The success of our railway transportation system has been due largely to the vigorous and resolute policy of our Governments in the matter of railway development, which contributed the Intercolonial Railway, and latterly the Transcontinental system—our investment in which exceeds $200,000,000. Public aid has been given to private railway systems to an even greater extent, and guarantees of bonds have been made to an amount closely approaching $300,000,000.

As regards marine transportation, we have had no such policy. We have constructed a canal system that since Confederation has cost us over $100,000,000, but the canals so constructed are open to our competitors and over four-fifths of the traffic passing through the Canadian canals originates in the United States, and less than one-third of the ships using the canals are Canadian. In addition to the expenditure on canals, Canada has spent something like $150,000,000 in aids to navigation on the Atlantic and Pacific coasts and on our inland waters.

Industrial Policy

Personally, I have but little faith in the success of any scheme for providing greater or more efficient transportation either through Government ownership, time charter or operation of a tramp steamer fleet, or by any other form of attempted control of ocean traffic by the Government. On the other hand the Dominion would be justified in making some considerable expenditure by way of aiding in the development of Canadian shipbuilding at the present time.

The iron and steel industry of Canada could never have reached the present output capacity save for the fostering influence of the combination of tariff protection and bounty, and I take it we have reached the position in Canada where even the most out and out "free trader" will admit that any sacrifice made by Canada to establish the steel industry has been fully warranted by the experience of the past eighteen months, for I assume that it will be agreed that if the iron and steel industry had not been developed in this country as it was, no munition business would have been possible in Canada to-day, and in that case the financial situation of the Dominion and the industrial condition in the large manufacturing centres would be quite different from what they are at this moment.

I am confident that when a return is made by the Minister of Finance it will be shown that the tax on the excess profits collected from munition and iron and steel manufacturers, will, before the war is ended, equal the entire total bounties paid out by the Dominion Government to iron and steel manufacturers from the inception of that policy in 1892 until the date when the bounties finally ceasesd.

Steel shipbuilding on a comprehensive scale can be developed if the Government of Canada is prepared to grapple with the matter in a broad and statesmanlike way. The measure of assistance which the country should extend to the shipbuilding industry is a matter for Government decision. The present bounty is entirely ineffective and out of date.

The Alliance Power Co., Ltd., has recently been incorporated at Edmonton, Alta., with a capital of $250,000.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

GAUGES IN MODERN MANUFACTURING PRACTICE—III.

By F. H. Mayoh.

THE accurate measurement of gears is a subject which, while it often gives the designer some uneasiness, nevertheless is easily taken care of by the use of the many styles of gauges provided for this purpose. Some of them are standard as for instance, gear depends largely on the manner of setting up the machine where they are cut it is oftentimes well to resort to testing fixtures or gauges.

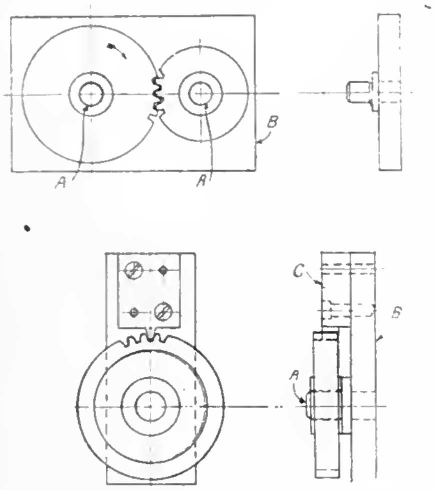

FIG. 13. GEAR TESTING FIXTURES.

A simple fixture for testing the centre distance between two gears is shown in Fig. 13 upper, and is simply two studs A, accurately located in a plate B. The gears are slipped over these studs and tested to see if the pitch diameter of the gear is correct and that the gears

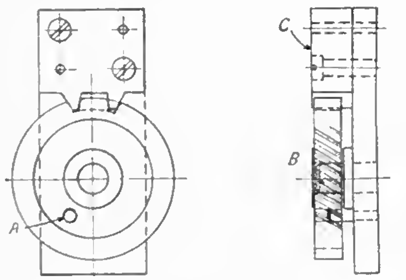

FIG. 14. FIXTURE FOR TESTING SPIRAL GEARS.

will run together in good shape. It is a good plan, however, to have a master gear of each diameter to test all the gears of a set that match with it in order to prove the pitch diameter of each gear, as otherwise the pitch diameter might be small on one gear and large on its mate although not interchangeable with any other gear of that size.

Another gauge for testing the pitch diameter is shown by Fig. 13, lower this consisting of the stud A over which the gear goes and the main plate B,

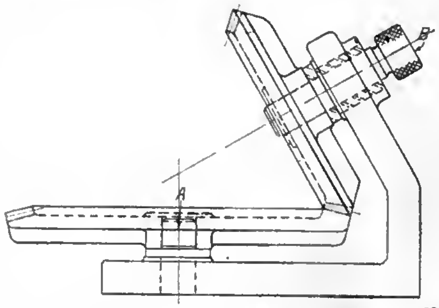

FIG. 15. BEVEL GEAR-TESTING FIXTURE.

with a plate C, which has a gear tooth cut on it to gauge the pitch diameter in the manner shown. Another gauge which is similar in appearance, but which gauges a spiral gear, is shown by Fig. 14. This gauge not only tests the pitch diameter, but also tests the angle of the spiral and its relation to the hole A, the construction being such that the stud B corresponds to the shaft on which this gear runs, the pin A is in a position to correspond to a dowel on the machine and the plate C is a gear tooth to match the angle of spiral on the gear. Similar fixtures to meet various conditions will readily suggest themselves for use on other styles.

Bevel Gear Testing Fixtures

A testing fixture for bevel gears is shown in Fig. 15, where one gear is placed on a stud as shown by A and its mate is held in position, the plug B being run through the bracket and into the hole of the gear thus providing a simple method of testing the working action of these gears.

The Use of Set Blocks

A convenient method of gauging which is often overlooked is the use of set blocks on jigs or fixtures which usually save the operator considerable time when setting up, and avoid much spoiled work, both very desirable features.

Four applications in the use of these set blocks are shown by Fig. 16. The upper left hand view shows a set block of a given thickness placed between a finished pad on a milling fixture and a surface milling cutter to set the cutter in the proper position for taking a cut. The view in the upper right hand corner shows the same set block between a side milling cutter and the finished pad at the side of the fixture which locates the cutter in its proper relation for taking a cut, when by locking the table in place the work being machined can be gang milled with the knowledge that it will come out correct without the necessity of cutting and trying. In the lower left hand corner an example of a set block being tried between two straddle milling cutters is shown, this block be-

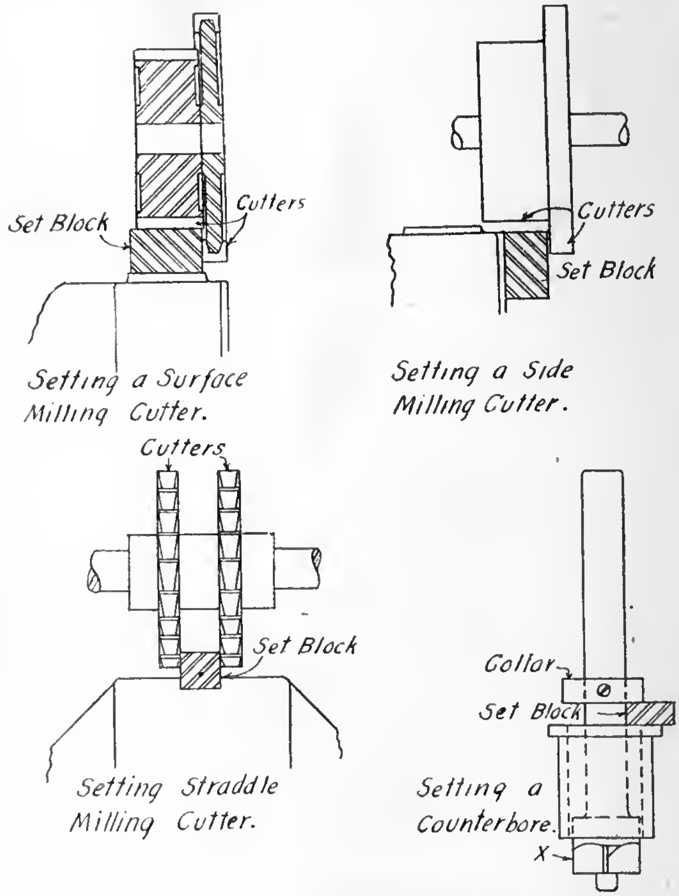

FIG. 16. APPLICATION OF SET BLOCKS.

ing set on the fixture back from where the cutters will work. It is necessary to drop the table of the milling machine with the fixture on it when setting the cutter and try the cutters over the

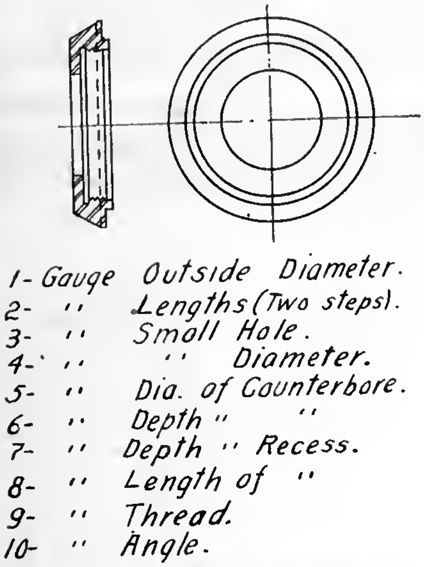

FIG. 17. GAUGING OPERATIONS ON SHRAPNEL SHELL FUSE RING.

block to set them for taking the cut when the table is raised and the machining on the work done.

In the lower right hand corner the method of using a set block for setting the collar on a counterbore in a drill jig is shown the idea being to bring the counterbore down till it touches the work surface (X). A set block of a thickness equal to the depth of the counterbore is then inserted between the collar on the counterbore and the bushing on the drill jig, the collar is set and the work counterbored till the collar comes against the bushing in the jig thus giving the correct depth.

Gauges for Testing Shrapnel Shell Fuse Rings

A complete gauging system for testing a shrapnel shell fuse ring after turning is shown. This ring, Fig. 17, is to be gauged as enumerated below the illustration and this is taken care of by the gauges shown in Fig. 18. The gauge A is for the largest outside diameter, the overall length and length to shoulder. The gauge B is for the small hole, C the diameter of shoulder, D the diameter and depth of counterbore, all of these being of the "go" and "not go" type. The gauge E tests the diameter of recess at bottom of thread for "go" and "not go" by means of the eccentric at the end. The end (X) of the gauge is first placed in the hole and the handle Y is made to turn the rod Z in the eccentric hole until the end V hits in the recess and if the handle Y remains between the two lines, W the recess is the correct diameter. The gauge F is for length of recess by the usual process. Gauge G is for the thread which can be screwed on one end and not on the other. The gauge H tests the angle at the outside and the length of straight by holding the work up to light and sighting the angle for "go" and "not go."

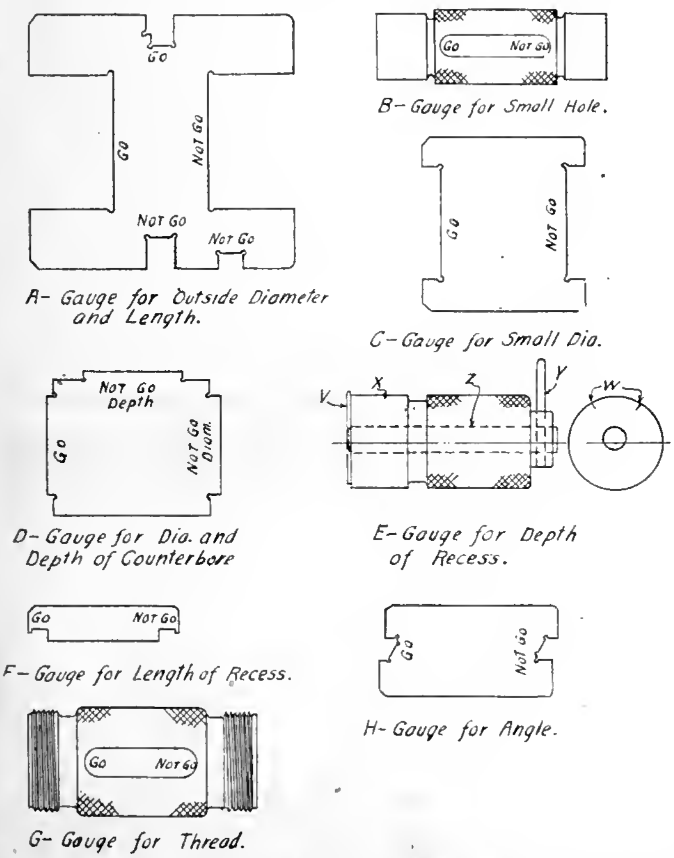

FIG. 18. GAUGES FOR DIMENSIONS IN FIG. 17.

Snap Gauges

Two types of standard snap gauges are shown by Fig. 19, one consisting of drop forged frame and four pins, and the other of drop forged frame and two adjustable pins, thus permitting varying of the limits to suit different conditions.

In addition to the many different types of gauges for the manufacture of machinery, there are also gauges for testing when assembling after the part are thoroughly gauged at the successive machine operations. Some of these are gauges for testing units as they are assembled, and test plugs with indicators for testing the alignment of the machine before sending it out as the finished product. Then there are hardness testing machines, pyrometers or in fact, in the highly standardized machine shop of

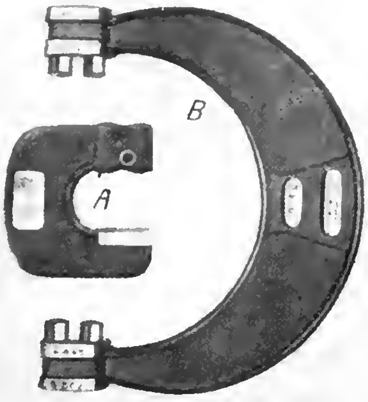

FIG. 19. STANDARD SNAP GAUGES.

multi-production, there are innumerable gauges or testing appliances devised often to suit the most trying conditions and just in so much as these meet their requirements so is interchanging ability secured.

A MILLING FIXTURE

By D. S. Mann

IN fig. 1 is shown a cast iron rod end or terminal which is used on the end of an engine side rod connecting same to rocker arm. The first operation on this piece was milling in sides of the rounded end before reaming the $1\frac{1}{2}$ inch hole thru same. The other operations, drilling, tapping and facing were performed after the milling operation, the piece being located from the previously milled surface.

In Fig. 2 is shown the fixture which is used for holding the piece while milling. The cast iron body is bolted to the miller table, and is provided with a V

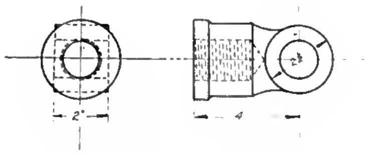

FIG. 1. CAST IRON ROD END.

for centering the rounded end of the piece to be milled. The other end is centered in a tool steel cup which is attached lossely to the end of the large capstan screw operating directly in the body of the fixture and at the same height as the center of the V. The hardened steel cup is provided with a plug which fits loosely into the center of the screw and is held in place by a small counter sunk head cap screw.

The fixture is made high enough so that 12 inch straddle mills may be used and is about 1/4 in. narrower than the faces to be milled, so that it may be readily placed quite accurately without the use of any centering device at the one end, and since all the later operations are located from the milled surfaces the accuracies of these are thereby guaranteed.

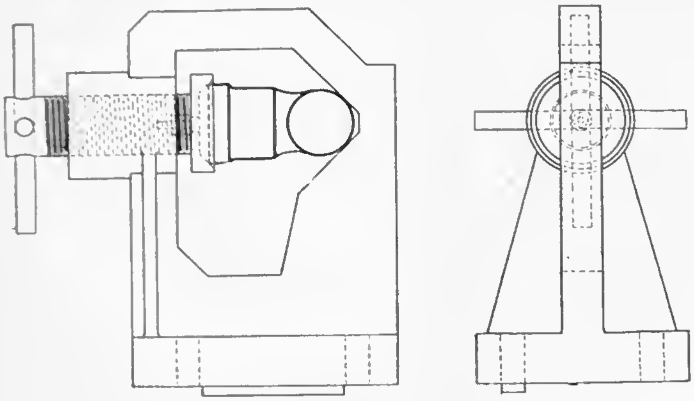

FIG. 2. FIXTURE FOR HOLDING ROD END WHILE MILLING.

This arrangement is very quick acting and there is plenty of room for the hand in putting in and taking out the pieces. The direction of cutting is downward so that all vibration is eliminated. The screw was made long enough to accommodate several lengths of these terminals.

ELIMINATING UNNECESSARY DIMENSIONS FROM BLUE PRINT SKETCHES

By F. H. Mayoh

THE accompanying drawings show a method of eliminating many minor details on drawings, which is of considerable value as a time and trouble saver in putting small jobs through the shop. In many shops special tools have to be made up frequently for new jobs, and, though the tools vary in size, their general design or type remains the same. The preparation of new drawings and tracings for these tools can be largely done away with if the dimensions be left off the original tracing and suitably shaped spaces blackened, which come out white on the blueprint. It is then a simple matter at any time to make up a drawing for a tool with the dimensions varying from previous ones, thus avoiding delay in drawing, tracing and printing.

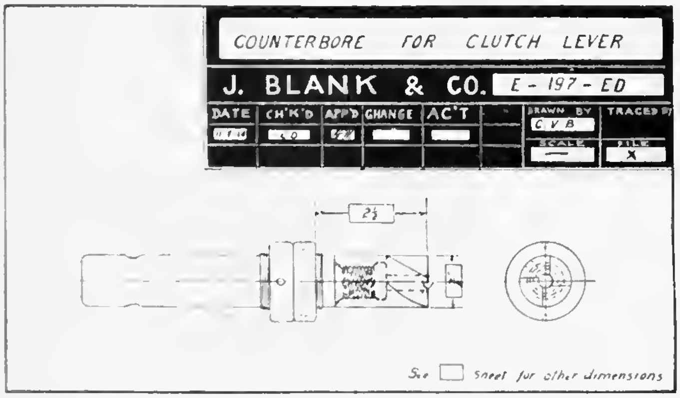

FIG. 1.

Fig. 1 shows a counterbore, the shank of which is made to standard dimensions, and the counterbore itself is interchangeable for different sizes. In making new heads it is only necessary, therefore, to give the two sizes shown, as the drawing for the shank is indicated by the footnote at the bottom of the sketch.

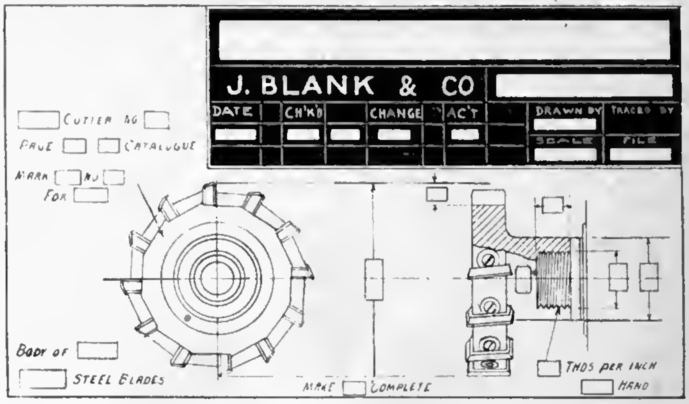

FIG. 2.

Tools of widely varying form are shown in Figs. 2 and 3, the former being a large inserted tooth cutter which screws on to the nose of the milling machine spindle, while the latter shows a gang of metal slitting saws arranged on an arbor. The general purpose of this system of making one tracing for each standard design can be readily comprehended from these examples.

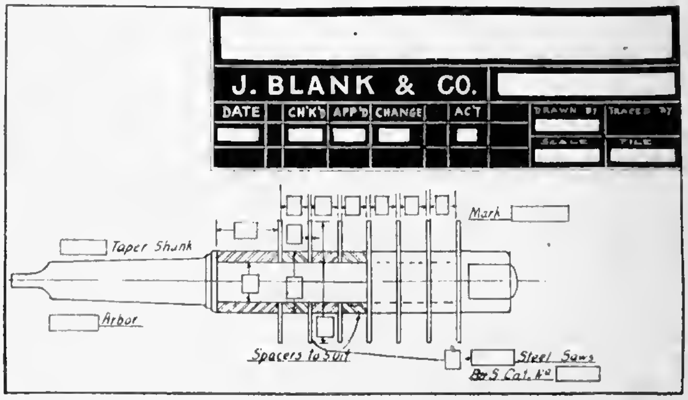

FIG. 3.

STEAMSHIP SERVICE TO WEST INDIES

IN 1913 a contract was concluded between the Dominion Government and the Royal Mail Steam Packet Company providing for a fleet of Mail and Passenger steamers to run fortnightly from St. John and Halifax to the West Indies and Demerara (British Guiana.)

It is pleasing to record that the European War, which has affected overseas trade more or less all over the world, has in no way interfered with the sailings of these steamers which have been maintained without a single break.

It is worthy of note that whereas freight passage rates all over the world have increased enormously, in part owing to the scarcity of tonnage, and in part to the greatly increased cost of working expenses, insurance rates, etc., the rates from Canada to the West Indies, and vice versa, have been maintained at a level that has inflicted no hardship on anyone—the rates being well within range of the enhanced prices producers and others are obtaining for their goods.

It may be truly said of this Canadian service, which owes its inception to Sir George E. Foster, K.C.M.G., the present Minister of Trade and Commerce, that it is a real "Link of Empire," as apart from the close relations it establishes between the Dominion and the 'British" West Indies, it is for the time being, the only regular, "all-red" means of communication between the Mother Country and the West Indies.

The Milton Hersey Co., chemists and engineers of Montreal have opened an office in Winnipeg with B. T. Melsted as manager.

Factors and Influences in the Heat Treatment of Steel-I *

By G. W. Pressell **

The war-created industry of shell-making, which at the moment overshadows in large measure every other form of manufacturing activity in Canada, as elsewhere throughout the world, has incidentally directed special and particular attention not only to the production of the steel of which these missiles of destruction in their fundamental consist, but to the various phases of steel treatment required for general purpose mechanical engineering products.

STEEL is not a simple substance like pure iron, gold or copper, but a complex artificial product. It is composed of groupings of many elements which enter into its make-up like granite rock is built up of the mineral quartz, mica and feld-spar. These elements as they may be called, are only visible with the aid of the microscope.

The term micro-structure has been given to what is thus brought to one's view. Upon etching a highly polished piece of steel this granitic structure is made apparent through the action of the etching medium-acid or other corrosive or abrasive material, which affects the elements variously, causing each to assume a color or structure peculiar to itself.

Mineralogical names have been given to the constituents of iron and steel, and pure iron, or rather carbonless iron, considered as a microscopical constituent, has been called "Ferrite." The ferrite of commercial grades of iron and steel is not pure iron, but rather a solid solution of iron holding small amounts of silicon, phosphorus and other impurities.

Pearlite is a formation in steel made up of definite proportions of iron (ferrite and iron carbide (cementite). The percentage of pearlite in steel is in proportion to the percentage of carbon content. Cementite is chemical combination of iron and earbon approximately 93.3 per cent. of iron and 6.67 per cent. of carbon.

Like most substances, these combinations of elements are decomposed by the action of heat, new ones being formed. Water at 60° Fahr. is a liquid. It is likewise a liquid at 211° Fahr., but at 212° Fahr. it becomes vapor or steam. The elements ferrite and pearlite remain as such up to a temperature of from 749° C. (1380° Fahr.) to 845° C. (1480° Fahr.), depending upon the quantity of each present, when they decompose, forming a new constituent known as "Martensite."

Now this "Martensite" differs materially in its properties from either ferrite or pearlite, in that, if preserved by quenching the steel, it will be found hard and brittle, while pearlite and ferrite are soft and tough. Again, ferrite and pearlite attract the magnet under all conditions, while the new constituent, "Martensite" in its hot condition does not; but in its cold condition it acts the same as ferrite and pearlite.

On account of the close relation existing between the treatment and structure of steel, and the structure and physical properties, it is essential that one realizes the importance of gaining a knowledge of what is called the critical points in steel, in order to lay the foundation for its heat treatment.

Thermal Critical Points of Steel

If one should watch the slow heating of a piece of steel in a furnace, it would be noted that the temperature of the steel gradually increases with the increasing heat of the furnace until a temperature is reached when the steel may become slightly darker or cooler than the furnace. As the heating is continued, the piece will again assume the temperature of the furnace. In the rising heat the darkening of the piece of steel is due to the absorption of the heat to convert ferrite and pearlite into martensite.

If the furnace be permitted to cool slowly, during some point in the process the steel may become brighter or visibly hotter than the furnace, after which it assumes its normal rate of cooling and continues on down to atmospheric temperatures. This rise in temperature in cooling indicates a giving off of heat, which is caused by the conversion of the martensite back to ferrite and pearlite.

A transformation of the constituents composing the steel accompanies these thermal changes—as for example on heating, the decomposition of ferrite and pearlite to form martensite, as mentioned above, or vice versa, the decomposition of the martensite into its constituents ferrite and pearlite, as the case may be, during cooling.

The temperatures or points occurring during the heating and cooling when these changes take place are called the critical points of steel. To distinguish between these two points, or ranges of points, those occurring on the heating are termed "Decalescence" and those on the cooling "Recalescence" points. When the various critical points occurring in steel are considered collectively, the range of temperature that they cover is called the critical range. The critical range may include one, two, or three points. The meaning of the expressions "Critical Range on Heating" and "Critical Range on Cooling" is obvious. These ranges have a value which is of great importance in practical work.

The decalescent and corresponding recalescent points do not occur at exactly the same temperature, the decalescent points generally occurring from some 25° C. (77° Fahr.) to 50° C. (122° Fahr.) higher than the recalescent. It does not follow, however, that these two points are not the opposite phases of the same phenomenon. The fact that the critical point on cooling lags behind the point on heating and vice versa is evidently a case of hysteresis, so often observed in physical phenomena, implying a resistance of certain bodies to undergo a transformation, when theoretically the transformation is due. The slower the process of heating and cooling, the nearer will the two points approach each other, so that with infinitely slow cooling and heating they would undoubtedly occur at exactly the same temperature.

Mechanical Treatment of Steel

The principal purpose of working steel is to shape it into the desired form. Its structure and physical properties are dependent on the care in working and the heats used. The mechanical working aside from machining is classed under two heads, namely: "Hot" and "Cold" working.

The finest grain size obtainable is undoubtedly that existing just as the steel has passed through the critical range on a rising heat. Hence, starting out with steel just below its solidification or undisturbed cooling, the grain size increases until the cooling has passed through the critical range, and the grain size at this stage will be the resultant size at the cold temperature. Taking the same piece of steel, for instance having a coarse structure, on heating there will be no change in grain size until the critical range is reached; there the coarse crystals break up and at the upper critical point form the finest possible structure. Continued heating.

*From a paper read before the Canadian Railway Club, Montreal.
**Metallurgist, E. F. Houghton & Co., Philadelphia, Pa.

however, above this point will again coarsen the grain.

As we have stated, undisturbed cooling is a condition necessary for crystalline growth, a coarse crystalline structure can, however, be partly prevented or broken up by vigorous hammering. If this hammering ceases above the critical range, crystallization again sets in and the structure is the coarser the higher the temperature above the critical point at which the work stops. The finishing temperature in working, then, should be for the best results at or just above the critical range.

The question arises, why not continue working the steel until it is cold? This would be a detriment, inasmuch as the grain structure is formed in the critical range and "cold working" causes distortions and strains to set up in the grain which result in decreased ductility and even brittleness. This effect is more pronounced the lower the temperature below the critical point at which the steel is worked. Mechanical working provides a means to shape steel to form by forging, refines the grain size and tends to increase the density of steel decidedly more than the steel possessed originally from the mills where rolled. High-grade steels are hammered at the mills into bars and rolled to proper size.

Annealing

Inasmuch as the annealing process has an important bearing upon the physical properties, the mechanical treatment and the subsequent effect on the heat treatment of steel after machining, it is essential that the basic principles of this operation be thoroughly understood. The purpose of annealing steel is: 1st—To increase its softness and ductility and facilitate subsequent machining operations; 2nd—To remove existing coarseness of grain and secure a desirable combination of strength, elasticity and ductility for the resisting of strains; and 3rd—To relieve internal stresses, such as are induced by forging, rolling or by non-uniform contraction in cooling. These changes of physical properties are due to the changes of structure caused by the heating operation, which operation consists essentially of three parts: 1st—Heating the steel to the desired temperature; 2nd—Holding at the temperature until the steel is thoroughly heated; 3rd—Cooling.

Since all crystallization is obliterated in heating steel through the critical range, it is necessary then to heat the steel through this range as the first step in the annealing operation. Heating to a temperature below the critical range would induce no structural change whatever, but should you heat considerably above the range you would again bring about a form of crystallization, which is detrimental. The following ranges of temperatures are recommended by the Committee on Heat Treatment of the American Society of Testing Materials. They also state that for steels of a manganese content greater than .75 per cent. slightly lower temperatures are advisable:

Range of Carbon Content.	Range of Annealing Temperature.
Less than 0.12%	875° to 925° C. (1587° to 1697° F.)
.12 to .29%	840° to 870° C. (1544° to 1598° F.)
.30 to 49%	815° to 840° C. (1499° to 1544° F.)
.50 to 1.00%	790° to 815° C. (1454° to 1499° F.)

The time at which the steel should be held at an annealing heat is governed largely by the size of the piece. In order to bring the interior of large objects to an effective annealing temperature the outside may often be heated advantageously somewhat above the desired temperature. Therefore, a range of temperatures is given for each range of carbon content. The upper limit of this range applies to larger objects and also to the lower range of carbon content given.

The rate of cooling should be regulated to suit the carbon content of the steel and the physical properties desired. The higher the carbon the slower the cooling. Also the slower the cooling the softer and more ductile the steel and lower will be the elastic limit and tensile strength. Steel containing more than .50 per cent. carbon should cool slowly either in the furnace, lime or clay until it becomes black in color, when it may be removed. In case great softness and ductility is desired all steels should be subjected to slow cooling.

It is desired, of course, to have some definite range of temperatures to control the elasticity and ductility of the steel. For very high elastic limit and tensile strength heat to from 500° to 650° C. (932° to 1202° Fahr.). In this case the ductility will be low. Some steels, such as watch springs and shaftings, are annealed at 350° C. (662° Fahr.). Very little commercial annealing is done below 500° C. (932° Fahr.). For intermediate tensile strength, elastic limit and ductility best suited for the majority of cases, anneal at from 600° to 650° C. (1112° to 1202° Fahr.). For the greatest ductility with good strength and elastic limit, anneal at from 725° to 750° C. (1337° to 1382° Fahr.).

Internal stresses caused by forging or rolling are partially eliminated by heating steel to a temperature of from 538° to 649° C. (1000° to 1200° Fahr.) and allowing to cool slowly. The control of the annealing operation by definite heats and methods unquestionably prepares steel to respond better to hardening and treating, reduces the strains and distortions which are inevitable, and paves the way for a most uniform finished product. It is advisable to anneal high carbon steel by packing with finely ground charcoal in iron boxes and insert the fire end of the pyrometer inside of the boxes to assure that the pieces are heated to the proper annealing temperature and to obtain a check on the heat in the pot.

Tensile Strength

In referring to the tensile strength of steel, one usually implies those properties of the material known as the yield point, which is commercially called the elastic limit; the ultimate strength; the elongation, and the reduction of area.

A "stress" is an internal force that resists the change in shape and size of any material by an applied force, and when the applied forces have reached their final values, the internal stresses hold them in equilibrium. The simplest case is that of a rope, at each end of which a man pulls with a force, say, 25 pounds; then in every section of the rope there exists a stress of 25 pounds. Stresses are measured by the same units as those used for the applied forces, and generally in pounds.

A "bar" is a prismatic body having the same size throughout its length. If a plane is passed normal to the bar, its intersection with the prism is called the "cross section" or the "section" of the bar, and the area of this cross section is called the "section area."

"A unit stress" is the stress on the unit of the section area, and this is usually expressed in pounds per square inch. For example:—Let a bar 2 inches square be subjected to a pull of 4,000 pounds, the resisting stress is 4,000 pounds and the unit stress is 4,000 pounds divided by the area of the bar, which is 4 inches, or 1,000 pounds per square inch. When external forces act upon the ends of a bar, in a direction away from its ends, they are called "tensile forces." When they act towards the end they are called "compressive forces." A pull is a tensile force and a push is a compressive force, and these two cases are frequently called "tension" and "compression." The resisting stresses receive similar designations. A tensile stress is that which resists tensile force.

The terms "axial forces" and "axial stresses" are used to include both tension and compression acting upon a bar along the axis of the bar. The first effect of axial load is to change the length of the bar upon which it acts. The deformation of a bar which occurs in tension is called the "elongation," and that which occurs in compression is called "shortening."

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

THE MANUFACTURE OF LEATHER BELTING—II.*

By F. H. Small.**

IN our previous article on the manufacture of leather belting, it was stated, that if the belt maker always knew what qualities he wanted in the leather from which he made his belting, he could go far toward obtaining these by proper choice and application of tanning material. We enumerate these qualities as our experience has shown them:

Belting Qualities Desired

First—We need good driving surface, sufficient friction between belt and pulley to eliminate slippage as completely as may be, and to enable the belt to carry its load under minimum tension, thus avoiding useless waste of power at the bearings.

Second—Lateral stiffness, coupled with pliability, the stiffness to keep the belt from twisting and waving and to prevent its curling at the edges when shifted; the pliability to enable it to hug the pulley, wrapping itself round and so securing large arc of contact, and to enable it to alter its shape with the minimum of internal resistance as it travels round the pulley.

Third—Good tensile strength that it may carry its load without breaking.

Fourth—Little stretch, but considerable elasticity; the former so that it will need to be shortened as seldom as may be, i.e., will do its work uninterruptedly; the latter so that it may easily take up and let go its load as it travels round the pulley.

Fifth—Firmness or stability, much the same as lateral stiffness, so that the leather springs little when cut, holds its shape, remains straight and runs true on the pulleys.

Sixth—Resistance to external conditions, such as heat, moisture, chemicals, etc.; that it may do its work in any place, at any time, and enduringly.

Seventh—Low initial cost.

It is apparent that no leather can have all these qualities in the highest degree, for some of them are incompatible. Sole leather would do admirably as far as lateral stiffness, little stretch, and firmness are concerned, but would fail lamentably to satisfy the requirements of pliability, tensile strength, elasticity, etc. The best result we can achieve is bound to be somewhat of a compromise. We must aim to get the largest measure possible of the most desirable qualities in our leather, with the least necessary sacrifice of others. There is where the beltmaker who tans his own leather has a marked advantage in that he may bend all his efforts to so adjusting his tannage as to secure the best possible compromise. Quality belting demands then—first, suitable hides; second, suitable tannage.

*Presented at the annual meeting of the Providence Association of Mechanical Engineers (A.S.M.E. Affiliation), September 22, 1915.

**Chemist, The Graton & Knight Mfg. Co., Worcester, Mass.

Belting Leather Preparation

We now have the leather and may proceed to prepare it for making into belting. Of the hides which we have tanned only 50 per cent. may legitimately be cut up into belting and less than 40 per cent. will go into first quality belting. First, we reject the bellies, cropping or cutting them off at the flank; this loses us 25 per cent. of the hide. Next we cut off the shoulder at a point 4 ft. 4 in. from the tail, or, if the hide be exceptionally small, at a less distance; this loses us 25 per cent. more, leaving us for cutting into belting a "bend" which constitutes less than 50 per cent. of the original hide.

This bend has now to be curried, i.e., given a supplementary grease-tannage: set out—to give a smooth flat piece of leather—and then stretched. The stretching is done on frames in which the wet leather may be clamped and subjected to so much tension as desired, the leather being allowed to dry under tension on the frames so that an additional stretch resultant upon the natural shrinkage of the leather in drying is imparted to the leather. Before being stretched the bend is usually cut into a centre and two side pieces, inasmuch as the centre portion being more close fibred will not stretch as much as the side pieces and by being divided as above the leather can be stretched more in accordance with its capacity. After stretching, the leather is rolled and glassed to improve its appearance, and is then ready to go to the stock room.

When the leather is received in the stock room, it is sorted according to weight or thickness—which in this connection are practically synonymous terms—into extra heavy, heavy, medium and light, and then packed down for future use. The sides are packed in square piles, alternate layers at right angles, to keep the stock flat and straight and allow of a circulation of air through the pile, thus aiding and hastening the seasoning process. This seasoning is an often neglected, but most desirable operation, for the use of well-seasoned leather is as important in the manufacture of belting as the use of well-seasoned lumber is in building. Belts made from well-seasoned stock stretch less and more uniformly, retain their elasticity and wear longer than belts from green stock.

Producing the Belt

From the stock room the leather goes to the belt shop, where its manufacture into belt takes place. The first step in this process is to straighten one edge of the leather. Next it is cut into strips of various widths by passing between a rapidly-revolving circular knife and a guide, the strips being graded for width and roughly for quality as they come from the knife, and then stored in racks. From these racks the leather goes to the sorters, by whom it is most carefully graded, both for thickness and quality, and on their expertness depends the maintenance of the standard set for each brand of belt. Accurate judgment of quality depends on wide experience in handling leather and a good all-round knowledge of the specific characteristics of the leather in different parts of the hide, for it is a fact that no two square inches of hide are precisely alike.

Quality, however, is very elusive of definition when one tries to imprison it in the confines of a specification, and the buyer is fully as likely to be well served if he states his needs and trusts to the honesty of an established and reputable house as if he attempts to be his own judge. The author has in mind a large railroad buying belting according to a specification which called for the leather to be cut from strictly first quality belting butts, and they were getting it, necks and all. Inasmuch as a belt is no better than the poorest strip in it, similar to the chain that is no stronger than its weakest link, it may be imagined how well they were being served. Later when the author's company had an opportunity to supply this railroad with some belting, we were rather chagrined to have it rejected by the railroad inspector. Some rolls of stock belt of a grade distinctly inferior to that first offered were then submitted and accepted by the inspector with a cheerful response: "That's what we want; why didn't you give us that at first?" For

CHISEL COMPOSITION AND TREATMENT

IN a paper read recently before the Institution of Mechanical Engineers, the author, Henry Fowler, chief mechanical engineer, Midland Railway, Derby, England, said that very considerable attention has been given to the composition and treatment of tool-steel used in machine tools, but the three implements of the hand worker—the file, the chisel, and the hammer—have been comparatively neglected. While aware of the work recently done in testing the former of these, and knowing that there is little need of improvement with the last-named, Mr. Fowler believes that the chisel has not received the systematic attention its importance deserves. A close examination of the new and used chisels in the shop, over which he had control, confirmed that view, and the result was an effort to induce the Alloys Research Committee of the Institution to take up the matter. For various reasons this was not successful, so the matter has been dealt with individually.

The material usually employed for chisels is not bought to specification, but a well-known and tried brand purchased. In the chief mechanical engineer's department of the Midland Railway, after considerable experiment, it was decided to order chisel steel to the following specifications:—Carbon 0.75 per cent. to 0.85 per cent., the other constituents being normal. This gives a complete analysis as follows:—

	Per cent.
Carbon	0.75-0.85
Manganese	0.30
Silicon	0.10
Sulphur	0.025
Phosphorus	0.025

It is perhaps interesting to note that the analysis of a chisel which had given excellent service was as follows, its heat treatment was, however, unknown:—

	Per cent.
Carbon	0.75
Manganese	0.38
Silicon	0.16
Sulphur	0.028
Phosphorus	0.026

At the same time that chisel steel was standardized, the form of the chisels themselves was revised, and a standard chart of these as used in the locomotive shops drawn up. Figs. 1 to 10 show the most important forms of these, which are made to stock orders in the smithy and forwarded to the heat-treatment room, where the hardening and tempering is carried out on batches of fifty. A standard system of treatment is employed there which to a very large extent does away with the personal element. Since the chemical composition is more or less constant, the chief variant is the section which causes the temperatures to be varied slightly.

The chisels are carefully heated in a gas-fired furnace to a temperature of from 730°-740° C. (1346°-1364° F.), according to section. In practice the chisel, Fig. 1, is heated to 730° C.; chisel, Fig. 2, to 735° C. (1355° F.); and a 1-inch half round chisel to 740° C., because of their varying increasing thickness of section at the points. Upon attaining this steady temperature, the chisels are quenched to a depth of 3/8 inch to 1/2 inch from the point in water, and then the whole chisel immersed and cooled off in a tank containing linseed oil. This oil-tank is cooled by being immersed in a cold-water tank through which water is constantly circulated.

After this treatment, the chisels have a dead hard point and a tough or sorbitic shaft. They are then tempered or the point "let down." This is done by immersing them in another oil-bath which has been raised to about 215° C. (419° F.). The first result is, of course, to drop the temperature of the oil, which is gradually raised to its initial point. On approaching this temperature, the chisels are taken out about every 2° C. rise and tested with a file, and at a point between 215° C. and 220° C. (428° F.), when it is found that the desired temper has been reached, the chisels are removed, cleaned in sawdust, and allowed to cool in an iron tray.

A question which naturally will be asked is whether comparative tests of these chisels with those bought and treated by the old rule-of-thumb methods have been made. The author knows of no method of carrying out such tests mechanically, other than that of hardness by the Brinell or Scleroscope method; again, any ordinary test depends largely upon the dexterity of the operator. The opinion of foremen and others using the chisels as to the advantages of the standard treatment set out gives convincing evidence of improvement

The author is aware that questions may be raised as to why the chisels have not been normalized at about 900° C. (1652° F.), after forging and before hardening. This matter had attention when the question was first dealt with, but at that time there were no facilities for carrying out the work. These have since been provided in connection with certain other work, but although various chisels have been normalized in the manner mentioned, no advantage has been found in carrying this out.

Discussion

Sir Robert Hadfield, in opening the discussion, told about an old-world chisel from Ceylon, dating from the early years of the Christian era, which he had recently examined. The shaft portion of this chisel, he said, was nearly pure iron. How had its point been hardened? He suggested some sort of cementation process had been followed, for example, the heating of the wrought iron chisel in a charcoal fire and its subsequent quenching in water.

It was interesting to note that Mr. Fowler by his paper virtually advocated and defended the use of old-fashioned carbon steel as the best for chisel-making purposes. He himself would like to suggest that we might get improved practice by using an alloy steel, such as one containing 0.55 to 0.66 per cent. of carbon and 1.0 per cent. of chromium. Longer life might be one result of using such a steel. A committee, he thought, might with great advantage be appointed to inquire into the whole matter.

An armour-piercing projectile was to some extent analogous to a chisel—a "one-blow" chisel, as Captain Sankey reminded him, and, for such a projectile, alloy steel was, of course, essential. Considering that it had a striking energy of 40.000 foot-tons and could pierce a 15 in. plate in the space of one-thousandth of a second, we saw it was indeed a very rapid "one-blow" chisel.

Mr. Fowler stated that his chisels were first quenched in water and then in oil. Could he say what was the temperature of the point when the chisel was dipped into the oil? Was the chisel quite chilled off in the water or was some heat left in it to run up to the point between the two immersions? He was interested to notice that Mr. Fowler had found no advantage in normalizing his chisel steel after forging and before hardening it. This was to be expected, for the crucible steel of which the chisel stock was composed was very carefully made, and had, as delivered, great uniformity in its composition, so that normalizing coulld hardly be expected to improve its uniformity. The paper, he thought, was of great practical value. He would send copies of it

round to all his foremen, who. he knew would benefit by reading it.

Daniel Adamson desired to know if the author could trace any connection between the scleroscope or Brinell hardness number and the duty or efficiency of the chisel. The paper could only be regarded as a guide to the treatment of one particular steel. Could Mr. Fowler give any information which would enable members to extend the treatment to steels of other compositions?

W. H. Allen, while remarking that the paper was very difficult to discuss, intimated that some observations which he himself had made on the form and treatment of chisels were to be presented to the Institution shortly.

L. Pendred inquired whether all the chisels referred to in the paper were for hand purposes or whether some were for use in pneumatic tools. A chisel suitably hardened for hand use was not necessarily equally suitable for employment in a pneumatic tool.

Druitt Halpin suggested as a scientific means of testing chisels the use of a standard file-cutting machine.

A. W. Marshall said that the paper spearated the smith from the hardener and temperer. The heating of the steel to forge it had to be taken into account in planning the heat treatment required to harden and temper the chisel. and, in his opinion, the man who forged the chisel ought also to finish it ready for the fitter. How did the author deal with chisels which came back for reforging? Had he also standardized a re-dressing process?

T. T. Heaton asked what special steps were taken to test the quality of each batch of chisel steel and to see whether it was of the standard quality.

J. E. Brown asked how the cutting angles at the points of the chisels had been arrived at, and whether these angles were varied to suit the exact use of the chisel.

G. T. Gillespie also inquired regarding this matter of the cutting angles, and further asked what was meant by "metal tool," the title given to Fig. 10 of the paper.

A. B. Jackson asked how broken-off chisels were treated.

Mr. Gentry asked if, in quenching off in water, the chisel was moved up and down slightly so as to avoid creating a sharp line of demarcation between that section of the chisel which was dead hard and that portion which was soft. He would suggest that the secret of the success of Mr. Fowler's chisels lay in the fact that they were "let down" twice in two separate oil baths. He would like to know how the temperature of the second oil bath, 410 deg. Fah., compared with the temperature corresponding to a tempering color of dark straw with patches of purple.

John Dewranee said that the duty of a chisel was practically identical with that of a machine cutting tool. Had any one present ever used high-speed steel for chisels? He had heard of very mild steel hardened at the point by means of prussiate of potash being used for chisels, particularly pneumatic tool chisels.

W. S. Lockhart asked how the chisels

were served out. Were they given to the men as forgings for each individual to grind for himself? Would the steel recommended also be suitable for miners' drills? Fifty or sixty years ago in Cornwall it was the custom for the smiths when hardening picks and drills to powder some wolfram ore on their anvils and to throw it into the fire on top of the tool point. Wolfram was then not only valueless but actually an encumbrance. To-day it was used at Sheffield in much the same way as that of the Cornish smiths of half a century ago.

G. Watson supported the formation of a small committee to deal with the standardization of shape and treatment of small hand tools, including chisels. He suggested the possibility of using with advantage composite chisels consisting of expensive steel tips welded to less expensive steel shafts.

Author's Reply

Mr. Fowler, replying to the discussion, said he had from the first wanted the council to appoint a small committee to deal with the subject of his paper. If it were yet possible to do so, he thought it also ought to include consideration of pneumatic tools and of fet-

tlers' setts. He had not tried alloy steel for chisels, and from the discussion he judged that there were none present who had. The length of time the chisel was kept in the water depended upon the section of the chisel, but undoubtedly some heat was left in it, which before the immersion in oil ran back to the point. He could give no information leading to the correct method of correlating the scleroscope hardness number with the efficiency of the chisel. He looked forward with pleasure to Mr. Allen's contribution on the same subject.

All the chisels referred to in the paper, were for hand use. He would like to try the file machine test suggested by Mr. Halpin. The drawing down of the chisels was carried out by the smith, the subsequent heat treatment being performed by others. Repairs and reforgings were, it is understood, carried out by the staff of the heat treatment shop. He stated that the chisel steel was analyzed regularly for its carbon and occasionally for its other constituents to see, for example, that the sulphur content was not too high. The "metal tool" shown in Fig. 10 was intended for use on white metal.

The workmen were not supposed to sharpen their own tools, these being supplied sharpened from the store and when blunt or broken were supposed to be returned there. They had not a single grindstone in the whole of their erecting shop. Replying to Mr. Gentry, he said that the operator did move the tool back and forth in the water as and for the purpose suggested. He could not give the information asked for regarding the comparison of temperature and tempering color. His department, he informed Mr. Dewrance, used large milling cutters of mild steel, with case-hardened cutting edges, but so far they had not adopted this plan for chisels.

TRIALS OF THE MACHINE SHOP FOREMAN

By J. H. R.

THE selection of suitable mechanics is very often a serious, and sometimes expensive problem. If the foreman of each department had the opportunity of examining a man before he is chosen for the performance of certain work, much unnecessary trouble might be avoided.

In many large establishments it is the custom to have an employment agent, whose duty it is to hire all the help that may be required throughout the plant. When this official is a highly experienced man, the possibility of erroneous selection is reduced to the minimum; but unfortunately, in many instances, this office is held by a man with no practical experience, and who is therefore unfitted to judge on the qualifications of a man for certain positions. Many men might answer the questions put to them to the entire satisfaction of this official, but when passed on to the works foreman, it is sometimes found that the new hand is not only unfitted for the position for which he has been employed, but may know little or nothing of the elementary knowledge required for the successful operation of the work of the shop.

A Boring Mill Operation

Some years ago, in a large engineering works in Eastern Ontario, a man was engaged for the operation of vertical boring mill. The workman was told to report to the foreman on the following morning. When the man was taken by the foreman to the machine he was supposed to operate (a 5-foot vertical boring mill) he stood aghast, and remarked that he had never run such a large machine. In the hope of breaking him in on a smaller tool, he was taken to a 30 inch mill, but this also seemed out of his province. Doubt took possession of the foreman at this stage, and he requested the man to look about and point out the kind of mill he had been accustomed to operate. The suspicions of the foreman were somewhat when the "boring mill hand" pointed out a small radial drill. As this particular "mill" had an operator, it was the duty of the foreman to tell the new hand that he could not place him at the present time.

A Budding Lathe Hand

On another occasion, in a different factory, a young man, who was supposed to have served several years at the machine trade, was employed as a lathe hand. The first job given him was a number of small castings that required a stem turned to a certain diameter. The completion of this job was apparently quite satisfactory, and he was then given a batch of 36 shafts to turn; these shafts required journals turned on the ends, and the centre portion—a length of approximately 30 inches—to be turned to given dimensions.

While the roughing process was being performed on the end journals the foreman, owing to illness, was forced to leave the works. Before leaving however, he came to the writer and requested him to keep an eye on the new man, and see that he was given other work when these shafts were finished. Sometime later the new hand commenced the roughing out of the body, or long central portion of the shafts. From the opposite side of the shop I occasionally observed the young man. He had turned about a foot of the shaft when he stopped the lathe, came over to me and asked if I had ever found that lathe "cut into the centre". Thinking he referred to the lathe centre "cutting in", due to the expansion of the shaft, I told him to ease off the tail centre.

A New Size

The expression of his face told me that this was not the trouble, and further questioning brought the remark from him that "the size was getting smaller as the cut advanced along the shaft". I then told him to adjust the tail stock so as the lathe would cut parallel. As he walked slowly away I could see that my last suggestion had fallen on "deaf ears" and, thinking he might attempt to fix things by prying the end of the lathe over, I followed him back to his machine and set him going along the proper course. The shaft he had been working on however, had been started about 1-64 above the finished size, and where he had stopped, a distance of 15 inches, the size was 1-32 below the finished dimension, and this particular shaft was therefore spoiled.

When he had completed the batch, on the following day, he asked me over to examine them. After going over several and finding the variation within reasonable limits, I asked him if they were all as close as those I had tested. He replied that they were all within a "seventy-second". Suppressing a smile I said if they were as close as that they would pass. Sufficient to say when the foreman returned the man was released.

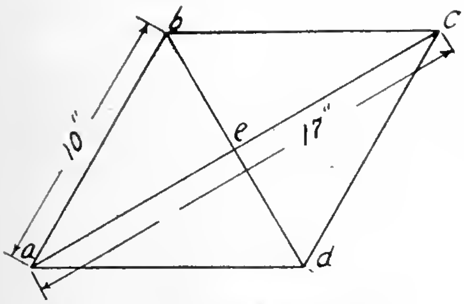
It is therefore quite evident, that as far as possible, where the foreman is responsible for the production of work, he should be allowed to have some say in the class of men who are placed under his charge.

Picric Acid.—Benzene, a redistillation product from benzol, is used in the manufacture of carbolic acid or phenol; this in turn is the basis of picric acid, which latter is the base of most of the high explosives used at the present time in the European conflict. When phenol (carbolic acid) is treated with nitric acid, a nitrate called tri-nitro-phenol is formed. Its only use is as an explosive. It is not only an explosive of itself, but more particularly is used as an ingredient of special explosive mixtures. Most of the new so-called shell-filler explosives are either picric acid or mixtures of picric acid salts called picrates. Among these are ecrasite (Austrian), lyddite (English), melinite (French), shimose (Japanese), etc. The exact compositions of these are secrets carefully guarded by the different governments.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division will be found a useful companion study.

Question—A square 10 inches on a side, is forced into a parallelogram, the long diagonal of which measures 17 inches; what is the area of the parallelogram, and the percentage of reduction?



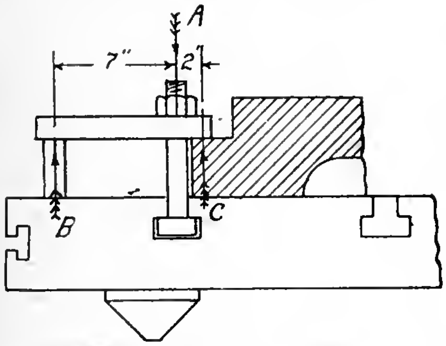
SQUARE AND PARALLELOGRAM QUESTION.

Answer—If the length of the long diagonal, a c equals 17 inches the length of the short diagonal or line, b d, can be found from the equation b e= $\sqrt{[(b\ c)^2—(c\ e)^2]}$ = $(10^2—8.5)^2)$= 5.267 inches.

Then as the several triangles are of similar shape and size, the area will equal the length of one of the diagonals multiplied by one-half the length of the other, or 17 $\times$ 5.267=89.539 sq. inches. The percentage of reduction from the original area of the square would be 100—89.54 = 10.46 or approximately 10½ per cent.

* * *

Question.—When clamping work on the lathe face plate or planer table, what is the best position for the clamping bolt?



CLAMPING WORK ON TABLE.

Answer.—The object of the clamps being to hold the work securely, it is obvious that the greater pressure should come upon the work, therefore the bolt should be placed as close to the work as possible; to illustrate, if the nut on the bolt is screwed down so that a pressure of 1000 lbs. is acting on the clamp at A, the reaction on the two supports B and C will be inversely proportional to their distance from the center of the bolt. As the distance between the two supports is 9 inches the reaction C will be 7-9 of 1000 = 778 lbs. and the reaction at B will be 2-9 of 1000=222 lbs. However, as circumstances will not always permit of this being done, the location of the clamping apparatus must always be governed by existing conditions.

Question.—With a feed of 3-64 inch on a 6 inch shell what will be the cutting speed in feet per minute if the shell is rough turned in 20 minutes; length of shell 17 inches?

Answer.—The length of the complete cut in feet will be $\frac{6 \times 3.1416 \times 64 \times 17}{12 \times 3}$ =569 feet. Speed in cutting feet per minute equals 569÷20=28.5 feet.

* * *

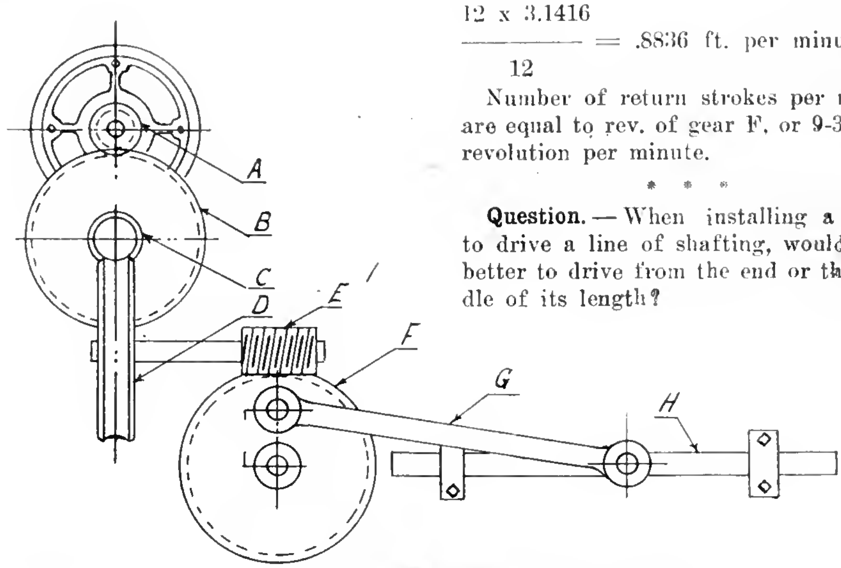
Question.—A motor operates a horizontal slide bar, through a link and train of gears, as shown in the sketch; how can we find the maximum linear speed and the number of return strokes per minute of the slide bar H, motor operating at 1800 rev. per minute?

Pinion A has 30 teeth; gear B 80 teeth; C, single thread worm, worm gear D, 60 teeth; E, double thread worm, and F a worm gear of 80 teeth.

Answer. — The speed of the driving shaft multiplied by the number of teeth in the driving gears, will equal the speed of the driven shaft multiplied by the number of teeth in the driven gears; thus, if X equals the speed of the gear F, then 1800 x 30 x 1 x 2 =X x 80 x 60 x 80 or X = $\frac{1800 \times 30 \times 1 \times 2}{80 \times 60 \times 80} = \frac{9}{32}$ rev. per minute, or 1 revolution in 3 5-9 minutes.

The maximum speed of bar H, will be when link G is in the position shown. With the mechanism in this position the speed of bar will approximate $\frac{9}{32} \times \frac{12 \times 3.1416}{12}$ = .8836 ft. per minute.

Number of return strokes per minute are equal to rev. of gear F, or 9-32 of a revolution per minute.



ILLUSTRATING SPEED OF SLIDE BAR.

* * *

Question. — When installing a motor to drive a line of shafting, would it be better to drive from the end or the middle of its length?

Answer.—Under general conditions it is advisable to have the main driving pulley placed upon the shaft as near the centre of its length as possible so as to move evenly distribute the strain throughout the shaft. When the drive is from one end the torsion on the shaft is sometimes very great, where a heavy load is carried. However local conditions must be carefully considered as it is sometimes impossible to follow a hard and fast rule, but in all cases better results are obtained if the heavy loads are kept as near the source of power as possible.

* * *

Question.—What is the proper clearance for milling cutter teeth, and the distance the tooth rest should be below the centre to obtain the desired angle, when grinding with a cup wheel, and also a disc wheel?

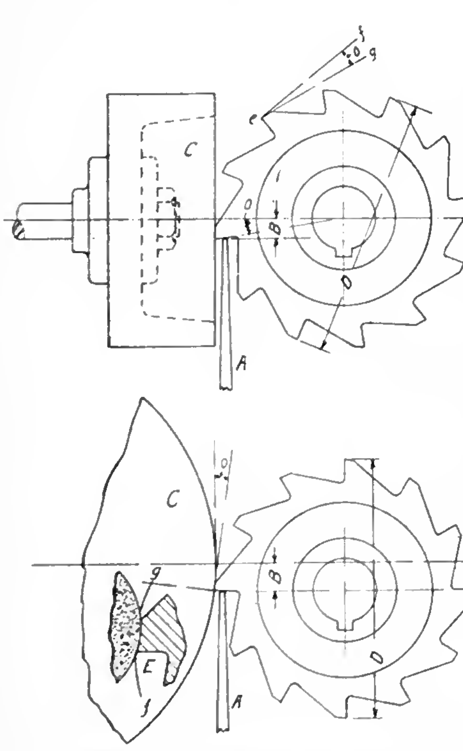
Answer.—The usual peripheral angle on the teeth of milling cutter is from 5 to 7 degrees, as shown in the sketch, the angle o representing the clearance. As the cutters are all of different diameters, it is obvious that the distance B, of the finger rest A below the centre line, must vary

for each size of cutter. To find this distance, when using a cup wheel, multiply the diameter of the cutter by .044 for 5 degree clearance angle, and by .06 for a 7 degree clearance.

When using a disc wheel we are governed by the diameter of the grinding wheel C, and the distance B, in which the work centre is below the centre of grinding wheel spindle. The distance B is found as in the case of the cup method, but by calculating with the wheel diameter. For example, to find the distance B when using a 6 inch wheel; 6 x .044 = .264 in., for 5 degree clearance, and for 7 degrees use the multiple .062. However, if a very small wheel is used, it may be necessary to add a little to the result obtained. This can be more clearly shown by referring to the exaggerated section E.

Question.—How can we determine the point of cross on crossed belts when the pulleys are of different sizes?

Answer.—The crossing point X will always lie nearer to the smaller pulley. The distance x b. will be to the center distance a b, as the diameter of the small pulley is to the sum of the pulley diameters. For example, a pulley 24



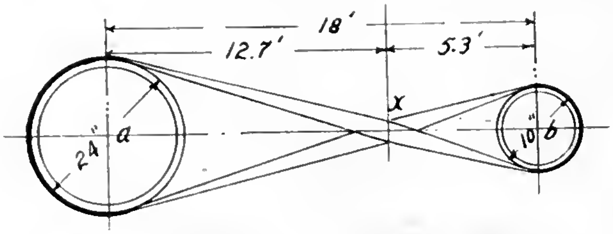
OBTAINING CLEARANCE ANGLE WITH CUP AND DISC WHEELS.

inches in diameter is to be connected by a crossed belt to a 10 inch pulley, shafts being 18 feet apart: where will the point x fall?

(x b) : (a b) : : d : D + d or

(x b) : 18 : : 10 : 24 + 10 then

$$(x\ b) = \frac{18 \times 10}{24 + 10} = \frac{180}{34} = 5.3 \text{ ft.}$$



POINT OF INTERSECTION OF CROSSED BELTS.

FOUNDRYMEN'S CONVENTION AT CLEVELAND

TO permit the foundrymen who will attend the annual meetings of the American Foundrymen's Association and the American Institute of Metals, which will be held in Cleveland during the week of September 11, to indulge in plant visitations to a greater extent than was possible at previous conventions, where two or three sessions were held daily, it has been decided by the program committee of this organization to have only one technical session per day, which will continue from 9.30 a.m. until the papers and discussions for that session have been disposed of, the hour of adjournment having been tentatively fixed at 1 p.m. This arrangement, it is believed, will meet with the hearty approval of all of the members of these societies, and it will enable them also to devote more time to the inspection of the exhibits of foundry supplies and equipment and machine tools, which will be held concurrently at the Cleveland Coliseum. The conventions of these two societies will open one day earlier than formerly, the final session to be held on Friday. The annual meeting of the American Foundrymen's Association, therefore, will continue for a period of five days, from Monday, Sept. 11 to Friday, Sept. 15, inclusive. The meetings of both the American Foundrymen's Association and the American Institute of Metals will be held at the Hotel Statler, which also will be the headquarters of these two societies, but headquarters for the exhibitors will be at the Hollenden Hotel.

The meetings of the American Foundrymen's Association and the American Institute of Metals will be opened on Monday morning with a joint session of both societies, and the program will include the address of welcome and response; the annual addresses of the presidents of the American Foundrymen's Association and the American Institute of Metals and the reports of the secretaries of these two organizations. In addition, the representatives of the American Foundrymen's Association on the "Joint Conference Board on the Training of Apprentices" will present a report and the report of the committee on "Safety and Sanitation" also will be heard.

A joint technical session also will be held on Tuesday, the program being limited to three papers, which will constitute symposiums on the following subjects: "Waste Foundry Sand; Its Reclamation and Disposal," which will be discussed in various papers that will treat the topic from different viewpoints: "Results of the Closer Co-operation of the Engineer With the Foundry," as relating to the manufacture of aluminum and brass castings, cast iron, malleable cast iron and cast steel and "Proper Gating of Molds," for the manufacture of aluminum and brass castings, cast iron, malleable iron and steel castings.

The annual business meeting of the American Foundrymen's Association will be held on Wednesday morning, Sept. 13, when officers will be elected and reports of the executive committee and the auditors will be heard. Also a report will be made by the special committee of five on the conferences which it held during the year that led up to the conduct of the exhibit under the auspices of the American Foundrymen's Association and the American Institute of Metals.

Three simultaneous sessions will be held on Thursday morning for the discussion, respectively, of gray iron, cast steel and malleable iron, while on Friday morning malleable iron and steel sessions will conclude the business of the convention. The program, as outlined, promises to be the best in the history of the American Foundrymen's Association, since the topics to be discussed are practical and relate to problems daily confronting the foundryman.

C. E. Hoyt, Lewis Institute, Chicago, exhibition manager, already has received a large number of applications for space and the indications are that the Cleveland coliseum, which affords a floor area of 60,000 square feet will be crowded to capacity. No assignments of space have yet been made, nor has a floor plan been prepared, although this will be done within the next few weeks, when requirements of the various exhibitors approximately will be known.

A meeting of Cleveland foundrymen will be held for the purpose of appointing committees for the entertainment of the visitors, to serve as guides in plant visitation and for the reception and entertainment of the ladies who will attend. It is probable that the annual banquet will be held at the Statler hotel on Thursday evening, Sept. 14. Negotiations now are being conducted to secure several speakers of national reputation to deliver addresses at the banquet.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

INDUSTRIAL DEVELOPMENT — I.

AT a meeting of the Institution of Civil Engineers, held recently, an address on "Industrial Development" was given by Harold Cox. He said that when peace was declared probably three million soldiers would return from the war seeking work, many thousands of munition workers would be discharged, and an enormous number of separation allowances would be discontinued. These changes must have a tremendous effect upon our whole social life—so serious that many people who had thought deeply about the problem even feared the possibility of industrial revolution after the war.

At present we had made no provision for these difficulties that were certain to come. There was a good deal of vague talk, but vague talk did not set industry in motion. They had to plan in advance, and he ventured to think that this was one of the problems for which the Institution of Civil Engineers was eminently adapted to deal. Engineers by their occupation were necessarily engaged in the ordinary course of business in planning great enterprises. Most of them, owing to the very wise system of their training, had experience of manual work and of work side by side with men who were now merely wage-earners. There must be some kind of collective effort, which did not necessarily mean Government action.

SECTION OF LARGE SHELL HYDRAULIC PRESS SHOP IN NEW BRITISH PROJECTILE-MAKING FACTORY.

External Aspect of Industrial Problem

There were two aspects of the problem —the domestic and the external. The extension of external trade was one of the principal objects we had to keep in view, not only from the economic, but also from the political point of view. He thought the greatest danger experienced from German trade was due to the manner in which the Germans had used their trade connections to build up political agencies in remote parts of the British Empire and in neutral countries. There was constant repetition of vague demands that the Government should do something in regard to external trade. Our recent experience of Government action did not encourage us to look for very much more from what the Government might do in the future.

It might be said that the Government did something for external trade. It maintained a consular service. He had studied a great many consular reports, and his impression was that a very large number of our consuls were gentlemen who had not been successful in the diplomatic service. In addition, we had consuls of foreign nationality, and sometimes they had been our trade rivals and our political rivals. Besides publishing statistics generally two years out of date, our consular reports, with a repetition which became wearisome, persisted in repeating the parrot cry that Britishers did not know their own business and ought to learn from the Germans.

He remembered one such report, which stated that Germans had captured the trade because they gave long credit, and three or four years later he came across another consular report from the same place which remarked that one did not hear quite so much about German trade as one used to; in fact, the only Germans one saw were a few seedy individuals trying to collect bad debts. These reports were a sheer waste of public money. He ventured to think no consular service controlled by the Government would ever be of practical use.

A Business Men's Consular Service

The question arose, why should not business men organize their own consular service? Some years ago Sir John Wolfe Barry started the idea that it would be possible for the various engineering societies in this country to organize a Standards Committee to establish common standards, to which all manufacturers should work. He got together a committee on which were represented that body, the Institution of Mechanical Engineers, the Institution of Naval Architects, the Iron and Steel Institute and the Institution of Electrical Engineers. He need not point out the enormous economy in manufacture which resulted from having standards.

The work done by the committee in the fifteen years it had been in operation was immense. They had established standards for hundreds of different articles, and these standards were reconsidered from time to time to meet new conditions. They were recognized throughout the world, and by their very existence had given a foothold to British trade in foreign countries. The committee had representatives of the Admiralty and War Office. It received grants in aid of its expenditure from his Majesty's Government, from Colonial Governments, municipal bodies, railway companies, gas companies and private manufacturers.

If a voluntary organization, started entirely by individual enterprise, could thus build up a system of standards which was of world-wide fame, was it not possible to conceive a larger organization representing practically all the trades of the country which should deal with the great problem of developing trade abroad—an organization for collecting trade information from agents employed abroad, systematizing that information and distributing it among the manufacturers primarily concerned?

Kingston, Ont.—The Street Railway Co. will instal two motor generators.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

TEN ROLL BAR STRAIGHTENER

A MACHINE which straightens all sizes of round bars from 1 in. to $2\frac{1}{2}$ in. diameter is illustrated in the accompanying photograph which shows a special ten roll straightener made by Brightman Manufacturing Co., Columbus, O. This machine is designed for handling rough bars, and bars which are straightened in this machine receive a high finish as well as being straightened in one pass through the machine.

The straightener consists of a bed with upright pedestal bearings at each end, which support a revolving frame having hollow journals. This frame carries the straightening mechanism, consisting of ten rolls with concave surfaces, the rolls being supported by bearing blocks having a swivel and screw adjustment. The roll supports are arranged on the revolving frame so as to project alternately from opposite sides, excepting at the receiving end of the frame, where two rolls are directly opposite. At each end of the straightener, tracks are provided, which are traversed by a gripping device which prevents the bar from revolving while it is being straightened.

The contact of the concave rolls on the bar produces varying speeds according to the amount of concave surfaces put on the rolls, at the same time a certain amount of slipping which occurs between the rolls and the bar imparts a very fine finish to the work. Rolls are adjusted at an angle to the shaft according to the diameter, each roll having a segmental line of contact with the surface of the shaft. This prevents gouging out or breaking of edges of flaws or cracks which may exist in the surface of the material and allows them to be smoothed over.

The capacity of this machine is from 20 to 40 feet per min., according to size of bar and speed of operation.

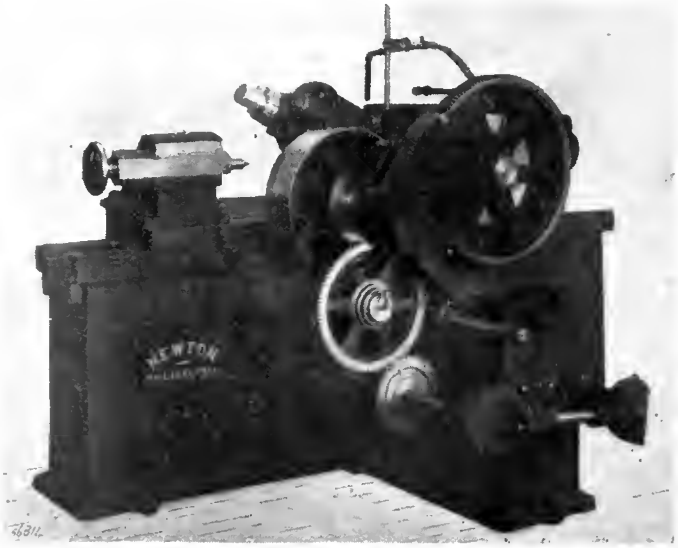


FIG. 2. REAR VIEW OF WORM MILLER SHOWING BELT PULLEY AND DRIVING GEARS.

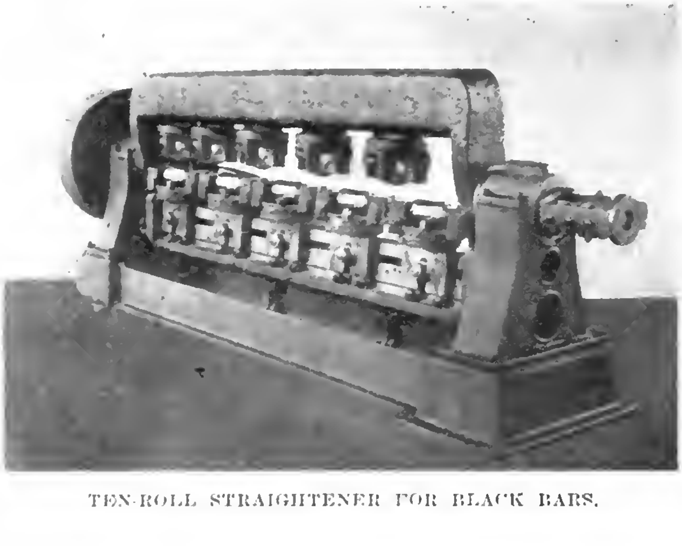
WORM MILLING MACHINE

THE accompanying photographs illustrate a worm milling machine which has been redesigned by the Newton Machine Tool Works, Inc., Philadelphia, so as to incorporate numerous improvements and alterations which have been suggested during the fifteen years since the original machine was built, the present machine, as offered to machinery users, having been in operation for the past year.

The operating side of the machine is shown in Fig. 1, the various adjustments being controlled by means of levers grouped within convenient reach of the operator. The driving gear is arranged on the rear side (see Fig. 2).

The work is supported by headstock and tailstock mounted on a table, which slides in ways on the top of bed. The cutter head, which also carries the driving gear, is gibbed to machined ways on the top of bed (see Fig. 2). All movements of the work and cutter are obtained from driving pulley, the drive to the cutter being through reduction gears to the large spur gear mounted on a shaft, at the inner end of which bevel gears transmit the motion to a shaft parallel with the cutter spindle. A taper bearing is provided at each end of the cutter spindle, which is provided with a hardened integral helical gear, which is driven by hardened gearing from the parallel shaft referred to.

The angularity of the cutter spindle is adjusted by worm gear, which provides a maximum range of 40 degrees on either side of the horizontal, spacing collars being used to locate the cutter accurately with the axis of the head. From



TEN-ROLL STRAIGHTENER FOR BLACK BARS.

FIG. 1. OPERATING SIDE OF WORM MILLING MACHINE SHOWING CUTTER AND FEED-CHANGE BOX

the driving pulley, power is also transmitted to the headstock through the train of gears and shafting around the lower part of the bed to a feed box on the front of the machine, which provides nine changes of speed to the main feed shaft.

Quick return of the work is controlled by the long lever at the right of the feed box, while the short lever immediately above the box throws the feed clutch in or out.

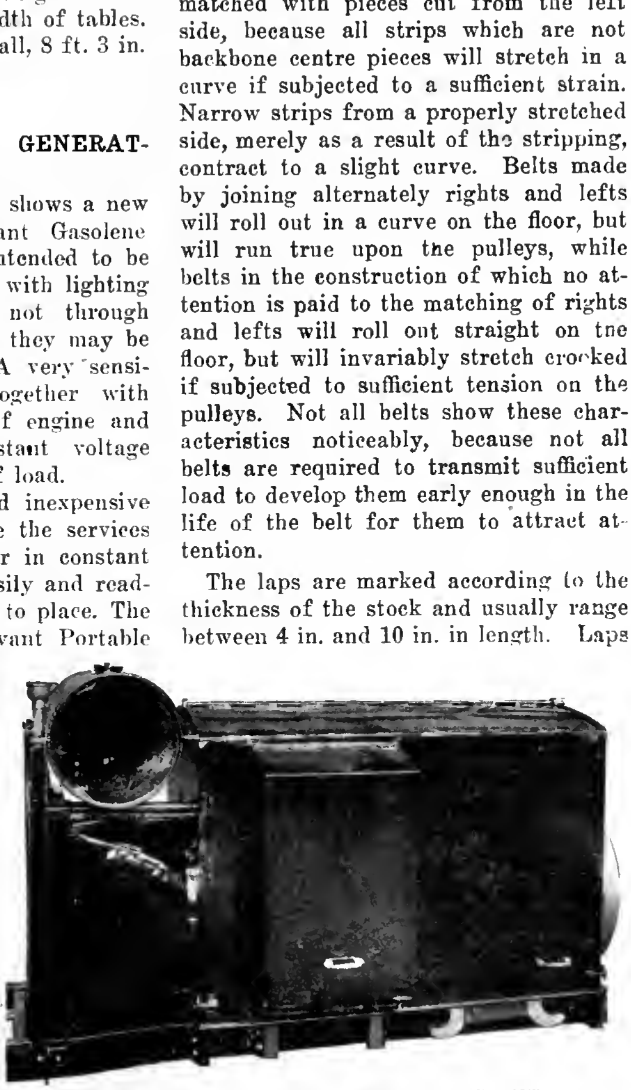
In operating, the turned worm blanks are forced on a mandrel, one end of which is inserted in the taper draw chuck in the hollow spindle of the headstock; and after being secured, is not again released until the worm is complete. All adjustments to and divisions for successive leads are controlled by a tooth clutch on the indexing gear, which provides leads from 1 to 6 inclusive and pitches from 1/4 in. to 9 3/4 in. All of the required gear combinations for right and left-hand threads are contained in the box which forms the headstock. Power is also transmitted through this box to the gears which are connected to the feed screw for travelling the table past the cutter.

Maximum distance, end of spindle to tailstock centre, 24 in.; height from table to centre, 8 1/4 in.; width of tables, 14 1/2 in.; size of base over all, 8 ft. 3 in. x 4 ft. 6 in.

PORTABLE GASOLENE GENERATING SETS

THE following illustration shows a new adaption of the Sturtevant Gasolene Generating Set which is intended to be used in direct connections with lighting and power circuits and not through storage batteries, although they may be so arranged if desired. A very sensitive governor control, together with other fineness in design of engine and generator, insure a constant voltage through wide variations of load.

These sets are easy and inexpensive to operate, do not require the services of an experienced engineer in constant attendance, and can be easily and readily transported from place to place. The unit consists of a Sturtevant Portable Electric Generating Set made up of a Sturtevant Direct Current Electric Generator direct connected to a Sturtevant Gasoline engine. A switchboard and gasoline tank is also included. A special type of disc fan is mounted on an extension of the generator shaft and arranged to blow air through a cellular type radiator. All of this apparatus is mounted upon two channel irons and the engine generator and switchboard are covered by a sheet metal housing, similar to an automobile hood.



PORTABLE GASOLENE GENERATING SET.

The engine is of the four cylinder, water cooled, vertical type with either four or six cylinders according to the size of the unit. Three sizes of these sets are built, 5 kw., 10 kw., and 15 kw. capacity capable of lighting 200,400 and 600 20 candle power tungsten lamps. Both engine and generator are capable of operating under an overload of 25 per cent. for two hours.

THE MANUFACTURE OF LEATHER BELTING

(Continued from page 369.)

our own ultimate good we have been trying to educate that railroad on this subject of quality in belting.

Matching the Strips

Returning to the process of manufacture, after the strips have been sorted, they then go to the fitters to be matched and have the laps marked. Pieces cut from the right side of the hide are matched with pieces cut from the left side, because all strips which are not backbone centre pieces will stretch in a curve if subjected to a sufficient strain. Narrow strips from a properly stretched side, merely as a result of the stripping, contract to a slight curve. Belts made by joining alternately rights and lefts will roll out in a curve on the floor, but will run true upon the pulleys, while belts in the construction of which no attention is paid to the matching of rights and lefts will roll out straight on the floor, but will invariably stretch crooked if subjected to sufficient tension on the pulleys. Not all belts show these characteristics noticeably, because not all belts are required to transmit sufficient load to develop them early enough in the life of the belt for them to attract attention.

The laps are marked according to the thickness of the stock and usually range between 4 in. and 10 in. in length. Laps must be longer on the shoulder end of the piece because hides become thinner, taper off faster, near the shoulder than near the rump, and longer laps are needed, therefore, to maintain a uniform thickness of belt. Shoulder ends are joined to shoulder ends and butt to butt, because the length of the laps match better, the thickness is more uniform, the stock is similar in quality and the component parts will, therefore, wear and stretch more uniformly. The laps are next searfed and prepared for cementing.

Cementing the Laps

The usual cement employed to stick the laps has for its basis animal glue. Each manufacturer is likely to have his own pet formula calling for certain additions to the glue solution and particular methods of compounding, but they all look much alike. By this it is not meant to disparage the cement, for a cement that will hold as long as the leather will wear is a necessary component of a quality belt. About twelve years ago saw the beginnings of the now indispensable waterproof cement. Laps stuck with this are absolutely unaffected by water, either cold or hot. Whatever cement is used the process of sticking is the same in its essentials. The surfaces of the leather to be joined are coated with the cement, put together in their final position, placed between the plates of an hydraulic press and subjected to heavy pressure. From the presses the belt goes to the inspector and then to stock.

The above description applies more particularly to single belting, but the processes are much the same if double or three-ply belting is to be made. A liberal quantity of stock which has been scarfed and the flesh side of which has been cleaned up with a scraper to remove grease, loose flesh, etc. (this being the side which is cemented), is placed upon the fitter's bench. He matches these together on a smooth surface against wooden blocks, which are his standard of thickness,the pieces being matched to secure as uniform thickness as possible, and so that the laps of one ply come about half-way between the laps of the opposite ply.

Adaptation to Operating Conditions

I wish to emphasize the fact that the idea that a belt is a belt and one need merely cut off a piece of the requisite length and put it on the pulleys is no longer tenable. Proper mechanical conditions and adaptation of belt to drive are just as essential to economy of operation as is the suiting of a motor to the work it has to do.

ORGANIZATION A FACTOR IN THE FUTURE OF THE ENGINEERING INDUSTRY

EVERY week seems to bring additional and more conclusive evidence of the intention of the Entente Allies to set their house in order commercially with special reference to German methods of the past and suspected efforts of the future.

The International Parliamentary Economic Conference of the Entente Allies which opens at Paris to-day, is an event which serves notice on the world of commerce that the union of trust and sympathy between our allies and ourselves which is such an outstanding characteristic of the present struggle, will not be allowed to fade away after the termination of active hostilities, but will be kept alive by such international co-operation in the realms of legislation and commerce that never again will it be possible for barbarian races to masquerade under a veneer of civilization.

As an active participant in the war and prospective participant in the world's future trade, Canada is more than concerned in the questions to be discussed at the conference, among others being such vitally interesting subjects as measures of precaution against the invasion of the markets of the Allies by German products upon the conclusion of peace; measures for repairing the damages of war; agreements in regard to the international transportation of merchandise; the creation of an international patent bureau; internationalization of the law-governing corporations, etc., etc.

Although these measures are at the moment being merely discussed with a view to bringing about preliminary agreements in regard to the various proposals, the solidarity of the Allies is made very evident by the fact that such proposals have been made. The ultimate object of all such measures is, of course, to insure the supremacy of law and order, and while this will be largely insured by restraining ruthless ambition on the part of the enemy, it will also be accomplished by corresponding encouragement to and advancement by our Allies and ourselves.

But, however much may be accomplished by such meetings, it must be constantly borne in mind that such events are merely beacons pointing the way for our future progress and that without sound judgment and consistent effort on our own part, the benefits which ultimately accrue will be anything but proportionate. In this connection particular reference might be made to the activity at present being shown by the engineering industry in England, on Tuesday, March 24, the Council for the Organization of British Engineering Industry held a conference at Manchester to discuss the conditions of the engineering trade after the war. A special committee of the Organization stated, as a result of their inquiries, that British engineers must organize without delay to meet the conditions which will follow the ending of the war. . . "Germany and Austria have gained the enmity of half the civilized world and the distrust of the remainder. All that is needed to enable us to reap the harvest already enriched by their blunders, is an organization that embodies a broader and loftier view of the responsibilities, opportunities and powers of our engineering industry.

That such a movement is representative of British manufacturers as a body was shown by the speakers present, who included T. C. Elder, of the British Electrical and Allied Manufacturers' Association; Dr. S. Z. de Ferranti, past-president of the Institute of Electrical Engineers; G. Goodbehere, chairman of the Engineering Section of the Chamber of Commerce, and several others.

The apathy of the British Cabinet to the repeated demand for the establishment of a Ministry of Commerce has forced the industry to exert itself to do all that is humanly possible to help itself, which it would fail to do if it did not organize a general association powerful enough to exert collective influence, in all foreign markets, to offer authoritative counsel to the Government, to stimulate scientific research, and to bring it into closer communication with scientific progress.

In view of the somewhat parallel state of affairs existing in Britain and Canada with regard to munitions work, the remark of one speaker that. . "the question was what was to be done in the 3,000 works where munitions were being made, some of which had already been warned that the demand for munitions in their cases was going to diminish, whether the war ended or not," is of especial significance to Canadian makers at the present moment, and in view of the hopes which are being built on the prospects of export trade from this country, the time is more than ripe for organized effort by the engineering firms of this country, not as a branch or department of an organization devoted to manufacturers generally, but a specialized body composed of engineering specialists whose every effort would be devoted to maintaining the engineering industry of this country at its present high level against all comers.

INDUSTRIAL NOTABILITIES

HENRY HAGUE VAUGHAN, 3rd Vice-President and Director, Dominion Bridge Co., is of English birth and parentage, having been born at Forest Hill, England, Dec. 28, 1868, son of Walter Henry and Sarah (Jones) Vaughan.

On completing his education at King's College, London, he entered the employ of Nasmith, Wilson & Co., Patricroft, subsequently being engaged at the Gorton Shops of the Manchester, Sheffield & Lincolnshire Railway, and the Nine Elm Works of the London & South Western Railway.

HENRY HAGUE VAUGHAN

Mr. Vaughan came to the United States in 1891, occupying successive positions with the Great Northern Railway, Q. & C. Co. and Railroad Supply Co., Chicago, till 1902, when he was appointed assistant superintendent of Motive Power, Lake Shore & Michigan Southern Railway, Cleveland, Ohio, 1902-1904; Superintendent, Motive Power, Eastern Lines, C.P.R., 1904-1905; Assistant to Vice-President, C.P.R., 1905-1915; resigned to accept Presidency, Montreal Ammunition Co.

He is also a member of Institute of Mechanical Engineers; Canadian Society Civil Engineers (Councillor, 1910); American Society Mechanical Engineers (Vice-President 1910-1912); President, American Railway Master Mechanics' Association, 1908.

Mr. Vaughan married Helen Polk, daughter of D. F. Polk, St. Paul, Minn., and resides at 18 Weredale Park, Montreal, Que.

His clubs are: St. James', Mount Royal, Forest and Stream, Royal Montreal Golf, Montreal Racket, Engineers (Montreal, President, 1911); Engineers (New York); Canadian Railway (President, 1909); Garrison (Quebec).

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., April 24, 1916.—The situation throughout the industrial fields is quiet, following the recent holiday period; but, activity is gradually assuming larger proportions. The manufacture of shells in Britain and France is constantly being increased, and the pressure in this country will no doubt be correspondingly decreased. The production of the raw and semi-finished material will, however, still continue to maintain its present position, as the requirements of foreign countries will still call for large supplies from this side of the Atlantic for a long time to come.

To offset the possibility of labor troubles, many manufacturers have voluntarily advanced the wages of their workmen; the increases in some cases being in the form of bonuses, payable at the termination.

Navigation is gradually taking on its summer activity, and much of the congestion of railway transportation will in consequence be relieved.

Steel

The general steel situation is unchanged, the undertone being one of comparative quiet. Buyers are not very anxious to place far future orders at present prices, and this is resulting in a reduction of placed orders. The volume of business on hand is so great, however, and the demand for contract supply so heavy, that the temporary relief is very slight indeed. Foreign inquiries are still coming in, but domestic requirements are being held over to a large extent pending lower prices.

The coke situation is becoming easier, owing to better shipping facilities, and also to the increased production. The oven price on Connellsville coke has declined 40 cents a ton for furnace and 25 cents for foundry, present quotations being $2.25 and $3.50 for prompt, and $2.50 and $3.25 for futures respectively.

Metals

Recent developments in copper have left the market in a very strong position, and prices are very firm, with an upward tendency. Tin is lower and inclined to dullness. Spelter is firm at present, but indications are that with increased facilities of production, lower prices may be looked for in the near future. Changing conditions in the lead market may materially affect the situation here, with a comparative reduction in prices. The metal situation is, however, showing little change over recent prevailing conditions.

Copper.—The strength of the copper market is still evident, the demand for this metal showing little cessation. The aggregate sales for the past few weeks is estimated at approximately 300,000,000 pounds, the largest percentage of this being taken by the British Government. The recent heavy purchases for export purposes have left the large producers in the position where they are unable to take further orders under four or five months' delivery. New York is quoting an advance of ¼ cent per pound, present prices being 28¾ cents for lake and 28½ cents for electrolytic.

Local dealers are holding firm on last week's prices, but intimate that higher quotations may be shown shortly.

Tin.—The dullness of the tin market has had much to do with the recent weakness and fall in prices shown. In addition to the quiet condition at present prevailing throughout the trade, the arrival of considerable tonnage and that afloat have had the result of relieving the situation and a decline of 2 cents is noted on the New York market. London reports a further decline on Straits tin, and present indications point to an easier market.

Local conditions are quieter, and quotations are lower, dealers here asking 50 cents, a decline of 1 cent.

Spelter.—The activity in spelter, somewhat pronounced after a period of comparative dullness, has again quieted down, but quotations are firm, and in some instances even stronger than those of last week. American prices show an advance of ¼ cent; New York quoting 19¼ cents per pound. An interesting feature in connection with spelter is that of the increasing facilities for production, which are expected to be put into operation during the present year. The capacity of the new plants will increase the supply of American spelter approximately 800,000 tons. However, as these will not be in operation for many months, they are not expected to have much effect upon present prices. Future inquiries are still active, and early deliveries are hard to obtain.

Dealers here report unchanged conditions, with prices firm at 23 cents.

Lead.—The abnormal condition of late prevailing in the lead market is beginning to show some signs of falling off, and lower prices may be looked for. New York reports a considerable drop in the demand for export metal, and unless the foreign requirements necessitate the placing of additional orders, the possibilities are that the domestic demand will not be sufficient to maintain the present high prices. It is believed that Great Britain is securing considerable lead from Australia, which will relieve the present pressure on the American market, with a resultant decline in present high prices.

Quotations are slightly lower on the New York market, but dealers here report no change, with prices firm at 10 cents.

Antimony.—The market in antimony is very quiet at present, and is developing weakness. The supply is greater than the demand, and prices are declining. New York is quoting 2 cents lower on Japanese and Chinese. Local antimony is quoted at 47 cents, a decline of 1 cent per pound.

Aluminum.—The market is quiet and unchanged, with prices firm at 68 cents per pound.

Machine Tools and Supplies

The situation in the machine tool industry is gradually assuming more normal conditions, and the activity is becoming less pronounced. The bulk of munition making machinery has now been delivered, and, with the exception of a few individual machines, no further orders are meantime in sight. The domestic demand, however, is very encouraging, and inquiries are constantly being received for many different classes of industrial equipment.

It is anticipated that with the approach of May Day some difficulty may be experienced, due to labor troubles, which will materially affect the situation at this time.

The demand for supplies is good, but some inconvenience is always evident owing to the delay in getting delivery.

Old Material

The supply of old material at present is very plentiful, but the demand is not so great; the market is quiet. Some business has been done in heavy melting steel scrap, and coppers are fairly active. The holiday season has had something to do with the recent dullness; but while business is light, prices are very firm.

Toronto, Ont., April 25.—The development of export trade is attracting the attention of business men more than it has done at any time in the past; the possibility of making certain goods in Canada, which are now being imported, is also being given quite serious consideration. Large numbers of industrial plants are fully employed on making war equipment, but as this activity will come to an end sooner or later, the necessity of looking to the future becomes more urgent as time passes. The Department of Trade and Commerce has already taken this matter up, but at the same time the active co-operation of manufacturers is necessary in order to guarantee the success of the scheme. The scarcity of labor in Ontario is becoming a serious matter on account of so many men enlisting, and manufacturers are experiencing considerable difficulty in keeping their factories running at anything like capacity. The situation is likely to become more acute and production will in consequence be curtailed. Manufacturers are also having much difficulty in obtaining raw materials in sufficient quantities to cover their requirements, and there is no sign of any relief in sight. Although the demand is good, the outlook from a manufacturing standpoint is not very promising.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel Market

The market continues very strong, and the demand for steel is as insistent as ever. The mills have all the business that they can take care of for the rest of the year, and even that does not cover all the requirements, as it is reported from Buffalo that an inquiry for over two thousand tons of bar material and other finished lines had been received from Canada. Some difficulty, however, is being experienced in closing the business on account of deliveries being so backward. The steel companies are beginning to fear a shortage of labor, a problem which it is expected will become more serious and difficult to remedy. The upward tendency in prices shows no sign of abating, and a number of steel products have advanced during the week. Bar iron has advanced 25c, and is now quoted at $3 per 100 pounds, the same price as steel bars. Steel angles have advanced to $3.50; refined iron, $3.25; Norway iron, $5.50; and band steel, $3.50 per 100 pounds. Twisted reinforcing bars are quoted at $3.25, plus extras for twisting. A new price for cold-rolled shafting has been made, and is now list plus 40 per cent. at warehouse. The wrought iron pipe market is very strong, and higher prices may be looked for. Boiler tubes have advanced in the States, and a similar movement may be expected here.

The demand for sheets in the primary market continues heavy, and operations at the mills are being maintained, notwithstanding the restrictions imposed by the shortage of sheet bars. The sheet market is irregular, and the usual differentials between the various gauges have practically disappeared on account of the big demand for the heavier sizes. Prices are unchanged, but very firm. The high cost of spelter continues to restrict the production of galvanized sheets, and the increased cost of steel has tended to cause a firmer market, despite the falling off in demand. The galvanized sheet market is irregular, and quotations firm and unchanged.

Reports from Sheffield, England, state that results obtained in the manufacture of tungsten powder have been most successful. The quality of the powder is entirely satisfactory, and a greater amount is being produced than was consumed by all Sheffield makers of high-speed tool steel prior to the war. There is still a shortage of supplies of tungsten ore, but it is hoped that arrangements will soon be made for a complete organization of these supplies.

Although there has been some falling off in the amount of new business in the United States market, there is no indication at present of any easing in the prices. The mills have enough business on hand to carry them well over into 1917, and the export demand, especially for bars for shells, is still very heavy. Forging billets have advanced to $68 per ton Pittsburgh. Steel bars have advanced, and are now quoted at 3c, and beams at 3.60c Pittsburgh.

Pig Iron

There is no development of importance to note in the pig iron market, and the situation is much the same as has prevailed for some months. Prices are unchanged, Hamilton and Victoria pig iron being quoted at $24 per ton.

Old Materials

The market is firm, but quiet, the only changes of importance to note being for copper and brass, which have advanced. The copper market has gained strength during the week, and prices of scrap copper have advanced in sympathy. The new prices are about 25c per 100 lbs. higher.

Machine Tools

Machine tool houses report business as having been more active during the week, the demand being principally for standard tools. Deliveries of this class

of equipment have improved, but are not as good as buyers would like. A better demand for large swing lathes is expected in the near future for machining large calibre shells. Machine tool builders are very busy, and firms making special tools are also actively employed.

Supplies.—The tendency for prices continues upward. One important firm has withdrawn prices on cutters, and will only quote on application for some other lines. The linseed oil market is weaker, the price being now around 97c for raw and $1 for boiled oil. It is expected that new and higher prices for cotton and wool waste will be put into effect on May 1. Prices of all imported glues have made a sharp advance.

Metal Markets

An advance in copper and declines in tin, spelter, and lead, are the principal features to note this week. Higher prices for copper were expected on account of the strong market, due to the recent heavy buying. The easiness in the tin market in New York follows a decline in London. The "Trust" price for lead is unchanged at New York, but the outside market is weaker. The spelter market is lower, due to the falling off in demand. Antimony and aluminum are unchanged, both markets being dull. Solders are quoted at the same prices as last week. Business locally is very good. This is due principally to the heavy demand for those metals used in the manufacture of munitions, but ordinary business has improved considerably.

Copper.—The market is strong and higher, with quotations nominal. Prices continue to reflect a strong advancing tendency, and the outlook is favorable to a high range of prices for copper for the rest of this year. Producers are sold up for at least five months, and with a continued heavy demand makes the position of copper an unusually strong one. Copper has advanced 1½c locally, and quotations are nominal at 31½c per pound.

Tin.—The spot market is dull and lower, both in London and New York, due to large arrivals of tin. Futures are, however, firm and unchanged. Tin has declined 2c, and quotations are nominal at 56c per pound.

Spelter.—The market is quiet and easier, the demand for spelter having fallen off. The market is being affected by the strained relations existing between the United States and Germany, and consumers are waiting the outcome. Spelter has declined 1c, and is now quoted at 22c per pound.

Lead.—The "Trust" is holding lead at 7.50c New York, but the outside market has declined. The outside market is still a trifle higher than the "Trust" figure, but this is not of any particular importance, as the demand for premium metal has practically ceased. Lead declined ½c locally, and is now quoted at 10½c per pound.

Antimony.—The market is dull and very little trading is being done. Quotations are unchanged and nominal at 48c per pound.

Aluminum. — The market continues dull, with quotations unchanged at 68c per pound.

Winnipeg, Man., April 22.—Jobbers are finding less difficulty meantime in securing deliveries of machine tools, while enquiries are less frequent. It is understood that most lines of tools can now be delivered within three or four weeks. The supply business continues fairly active, especially for transmission equipment. During the past few months, the demand for saw mill machinery has been exceptionally brisk, one jobber advising that last month he he sold $4,000 worth of such machinery to saw mills. All round, there has been considerable buying.

A number of large Winnipeg shops are very busy on grain elevators, of which many are under construction throughout the West. The demand for flour mill machinery is meantime limited. Taken all round wood-working machinery is quiet, although a number of planing mills here and there are ordering machinery. An order came in from Le Pas this week, and reports indicate that this district will offer good business this year, as there is considerable gold mining going on.

There have been a large number of changes in various iron and steel products. A number of lines of wire goods have taken a jump, new quotations being noted on screw eyes, screw hooks, etc. New prices on sheet tin were issued this week. Copper rivets and burrs have advanced. An increase is also reported in wrought iron pipe, both black and galvanized.

WELLAND LEADS AS POWER CONSUMER

THAT Welland uses more Hydro power than any other municipality in Ontario was the statement made at a joint meeting of the Council and the Hydro-Electric Power Commission held at Welland on April 20 by A. D. McKay, chairman of the commission. Welland's consumption of Hydro power has now reached 73,000 horse-power, and the payments for this power will net the Provincial Commission this year in excess of a million dollars. Welland municipal substation was built three years ago with a capacity of 2,000 horse-power to handle local light and power for the smaller users. This sub-station is now running at 2,160 horse-power in sixty days. The commission asks for $40,000 to build an 8,000 horse-power sub-station. The first year of operation the municipal system showed a surplus of $2,300. Last year it was over $8,000, and the commissioners say this year their surplus will be over $20,000. Since the first day of operation this utility has paid it own way. On the statement of the chairman it has saved to the users of light $60,000 since its inception.

CANADIAN-FRENCH EXHIBIT

THE Export Association of Canada, Ltd., Montreal, has learned through its London office that the exhibit of Canadian manufacturers, which was sent through the Association to the Fair of Samples in Lyons, France, created a very favorable impression among those who attended.

The Canadian exhibitors were fortunate in not having their exhibits held up whilst, owing to the requirement by the French Government of practically every means of transport, even some of the French exhibitors had not their exhibits in place on the date of the opening of the Fair.

The Export Association is extending its work into France as rapidly as conditions will allow. This step of placing Canadian goods before the people of France in an exhibition which will undoubtedly supplant the great Fair at Leipsic, has already exercised a strong influence upon the French people.

TRADE INQUIRIES

THE following trade inquiries have been received at the Department of Trade and Commerce, Ottawa. Particulars may also be obtained from the secretary of the Canadian Manufacturers' Association at Montreal and Toronto:

323. Belting Agency.—A firm in Glasgow, which formerly represented large German importing houses, wishes to obtain the agency of Canadian manufacturers of rubber, leather and canvas belting. Best references.

324. Brass Steam Fittings.—A Glasgow firm wishes to obtain the representation of a Canadian house for the above. Satisfactory references.

325. Steel Billets and Wire Rods.—A Coatbridge firm asks for Canadian sources of supply.

328. Galvanized Fencing Wire.—A Glasgow firm desires to know if galvanized fencing wire can be obtained from Canada. Supplies formerly procured from Belgium.

340. Nails.—A New York firm of exporters desires to be placed in touch with Canadian manufacturers of wire nails, wrought nails, and galvanized wrought nails, to be used for boat building purposes.

331. Wood Screws.—A firm of wholesale hardware merchants at Manchester wishes to be placed in touch with Can-

adian manufacturers of wood screws from ½ inch to 3 inches.

338. Machinery.—The director of a railway in India who has made arrangements for the building of a new plant wishes to be put in touch with Canadian manufacturers of saw-mill and veneering machinery.

CANADA STEAMSHIP LINES

THE most important Canadian vessel deal to be put through since the formation of the Canada Steamship Lines is practically closed. The Canada Steamship Lines will take over the vessel property of the St. Lawrence & Chicago Steam Navigation Co., of Toronto, the steel steamers J. H. G. Hagarty, E. D. Osler, W. D. Matthews and Iroquois, all the boats owned by the latter Company being included in the deal. The price paid for the steamers, which are among the largest and best Canadian vessels on the lakes, was not given out, but at the figures that boats are bringing, it will run into considerable money.

The Hagarty, which is the second largest Canadian steamer on the lakes, has a carrying capacity of 10,000 tons. She was built in 1914, and is 579 feet keel, 58 feet beam and 31 feet deep. The Osler, which was built in 1907, is 491 feet keel, 56 feet beam and 31 feet deep. She came out in 1907. The Matthews, which was built in 1903, has a carrying capacity of 5,600 tons. She is 358 feet keel, 48 feet beam and 28 feet deep. The Iroquois, which was built in 1902, is the smallest boat of the fleet. Her capacity is 3,500 tons, and she is 247 feet keel, 43 feet beam and 25 feet deep. The big steamer W. C. Moreland, which is being rebuilt at the Superior yard of the American Shipbuilding Co., was purchased by the Canada Steamship Lines some time ago.

Trade Gossip

The Magnolia Metal Co., New York, a well known concern making babbitt metals, have we are informed, erected an extensive plant in New Jersey for the smelting of antimony.

The International Time Recording Company of Canada, Ltd., which recently took over the interests of the W. A. Wood, Co., makers of the Globe Time Recorder, has now moved into its large new factory at the corner of William and Anderson Streets, Toronto. This event has especial significance at the present time due to the intimate connection between the Co's. product and the business conditions of the country, the increased output demanded being an accurate indication of present industrial activity. The new plant will come under the supervision of F. E. Mutton, general manager, formerly with the Gibbons Advertising Agency, and the National Cash Register. Arrangements have been made with the parent company in New York whereby the Canadian Company will take care of a large proportion of the export business done with the company's foreign representatives.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Chatham, Ont.—The Canada Flour Mills will instal several 200 h.p. motors in its power plant.

Hamilton, Ont.—The Steel Company of Canada have commenced the installation of two open-hearth furnaces at their plant here.

Hamilton, Ont.—The Cary Safe Co. are contemplating the erection of a plant for the manufacture of safes, vaults, doors, etc.

Sherbrooke, Que.—The Canadian Rand Drill Co. will build a machine shop to cost about $22,000. Anglins, Ltd., of Montreal, are the contractors.

Fredericton, N.B.—The Smith Foundry Co.'s plant was recently damaged by fire. The loss is estimated at $5,000, which is covered by insurance.

Niagara Falls, Ont.—The Dominion Safe & Vault Co., of Farnham, Que., have commenced work on the construction of a factory here, to cost about $7,000.

Hamilton, Ont.—W. Ellis has taken over the Maple Leaf Auto & Garage Supply Co., manufacturers of metal specialties, machinery, tools, etc., and will build a plant on Barton Street.

Montreal, Que.—A. D. Swan, 10 Phillips Place, engineer of the Anglo-Newfoundland Development Co., St. John's, Newfoundland, is in the market for cranes, transporters, electric conveyors, etc., for harbor equipment.

Welland, Ont.—The Canadian Aloxite Co., which has recently been incorporated, will establish a plant at Stamford, near here. It is understood that the company will make an initial investment of from $75,000 to $100,000.

Montreal, Que. — The Canada Iron Foundry Co., which completed a reorganization last fall, is contemplating building an addition to its plant at Three Rivers, Que. Either an entirely new plant will be erected, or a large addition added.

Halifax, N.S.—The Halifax Electric Tramway Co., Lower Water Street, is having a gas plant constructed in Halifax, and is calling tenders for the erection of a by-product building, cold storage building and for elevating and conveying machinery in connection with the plant. The engineer in charge is H. R. Barrett.

The International Nickel Co. has informed the Dominion Government of its intention to begin the erection of the Canadian plant immediately. The company is understood to have under consideration a site on the Atlantic coast somewhere in the vicinity of Halifax, although the exact details in regard to this have not been given.

Cobalt, Ont.—The Croesus gold mines in Munroe Township are considering the building of a mill. The incline shaft is being sunk from the 300 to the 400-foot level. A little ore from the Croesus has been milled in the mill on the Gold pyramid property, but the plant was so out of date that only a very poor recovery was made and the new mill, if erected, will contain the very latest practice.

Edmonton, Alta. — The Edmonton Power Co., which was organized by G. W. Farrell & Co., of Montreal, has made an agreement with the City of Edmonton covering a period of 21 years for a minimum annual supply of electric energy of 35,000,000 kilowatts at the rate of 1c per kilowatt hour during the life of the contract, the price to decrease on a sliding scale until the consumption of the city reaches 110,000,000 when the rate becomes ½c per k.w. hour.

Sir John Jackson, Ltd., of London, England, it is understood, has been awarded a contract for the dam and power house. Another important feature is an electric railway to be constructed to the site of the dam, and it is thought that two seasons will be necessary to complete the railway. The power line from the generating source will be brought down the south side of the Saskatchewan River.

Electrical

Welland, Ont.—The Welland Hydro Commission have asked the council for an appropriation of $40,000 to build and equip a new sub-station of a capacity of 8,000 h.p.

Port Carling, Ont.—The ratepayers will vote on a by-law on May 15 to sanction an expenditure of $1,000 for purpose of supplying electric lamps, etc., and connections.

Arthur, Ont.—A by-law will be voted on by the ratepayers on May 8, to raise $15,000 for the purchase of John Philip's electric lighting system and to provide for the cost of a plant to distribute electric power, to be supplied by the Hydro-Electric Power Commission.

Municipal

Ridgetown, Ont.—The ratepayers will vote on a by-law to authorize an expenditure of $10,000, to complete the waterworks system.

Saskatoon, Sask.—The city council have decided to submit a by-law to the ratepayers in connection with the proposed incinerator.

Cornwall, Ont.—The Town Council contemplate extensions to the waterworks system, and will require a turbine, pumps, and cast iron pipe.

Rodney, Ont.—A by-law will be voted on by the ratepayers to authorize an expenditure of about $7,000 on a light and power distribution system.

Port Moody, B.C.—The proposal to guarantee the ship-building company bonds to the extent of $200,000 passed by a majority of 99 for the measure.

General Industrial

Fort William, Ont.—The Paterson Grain Co., will build an addition to one of their elevators here.

Hamilton, Ont.—The Graselli Chemical Co. will build an addition to the factory at a cost of about $30,000.

Sandwich, Ont.—The Canadian Salt Co. will shortly begin the construction of an addition to their plant here.

Petrolia, Ont.—It is reported that a syndicate will build a flax mill here at an approximate cost of $100,000.

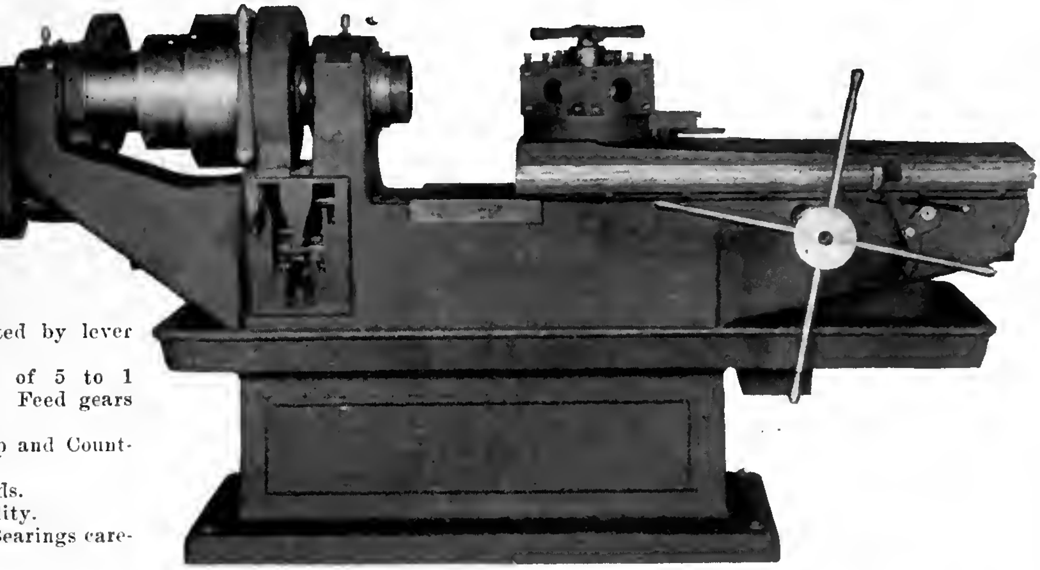
Mitchell, Ont.—The Mitchell Woollen Mills will make an extension to their plant. The cost will be about $5,000.

Medicine Hat, Alta.—The plant of the Dominion Harvester Co. here was de-

GREENSBORO TURRET LATHE

For Boring and Recessing Base of 4.5 and 6" Shells

Spindle is made of Carbon Steel, 8" diam. in front bearing and bored 6¼" diam. 8" deep, so part of shell is held within bearing to prevent overhang.
Spindle runs in heavy bronze bearings.
Head has friction back gear, 5½" belt.
Turret is bored for 3" Bars, has power feed with automatic stop.
Quick-change feeds operated by lever under head.
Turnstile has a leverage of 5 to 1 though gearing into rack. Feed gears made of steel.
Equipment: Oil Pan, Pump and Countershaft.
Weight: About 6,000 pounds.
Workmanship of Best Quality.
All Spindles ground. All Bearings carefully scraped.



THE A. R. WILLIAMS MACHINERY CO., LIMITED
TORONTO CANADA

"Here is a Die Head that you can depend upon"

A Geometric Self-Opening and Adjustable Screw-Cutting Die Head

They are being used with absolute satisfaction on every make of Screw Machine.

A micrometer adjustment makes possible quick and accurate variations for a tight or loose-fitting screw. The chasers open automatically, so that no backing off occurs to injure the thread. Length of thread accurately governed—short or long.

Arranged for cutting any diameter, pitch and form of thread. Right or left-hand. Flush to shoulder, where required.

Let us recommend the right sort of Die Head for your work.

The GEOMETRIC TOOL COMPANY
NEW HAVEN, CONN., U.S.A.

CANADIAN AGENTS: Williams & Wilson, Limited, Montreal.
The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg, St. John, N.B.

stroyed by fire on April 20. The loss is estimated at $65,000.

Port Arthur, Ont.—The Davidson-Smith Co. will build a million bushel addition to their elevator here. The contract has been awarded to the Barnet-McQueen Co., and the cost is estimated at $300,000.

Toronto, Ont.—The Flint Varnish & Color Co., which was recently incorporated, has purchased the Chevrolet Motor Co.'s factory. Additional buildings will be erected and equipment installed for making paints and varnishes.

New Toronto, Ont. — The Goodyear Tire & Rubber Co., will erect one of the largest and most up-to-date plants for the manufacture of tires in Canada at the corner of Ninth Street and Lake Shore Road. The factory will be a fireproof structure, and will be constructed of brick and steel. The total cost is estimated at $200,000. The site has been purchased.

Tenders

Burlington, Ont.—Tenders will be received up to Saturday, May 13th, 1916, for a two-ton combination chemical engine hose truck. Specifications on application. Jas. S. Allen, clerk.

Dartmouth, N.S.—Tenders for the completion of a foundry for the Williston Steel Foundry Co. are being received by the C. Hedley Williston, 504 Robie Street, Halifax, N.S. Estimated cost, $16,000.

Toronto, Ont.—Tenders will be received up to Tuesday, May 9th, 1916, for the supply of two gasoline-driven diaphragm pumps. Specifications may be obtained from the Works Department, Room 6, City Hall, Toronto.

Hamilton, Ont.—Tenders will be received up to Monday, May 8th, 1916, for supplying mechanical rakes and appurtenances for Gage Avenue pumping station. Plans and specifications may be obtained upon application to A. F. Macallum, city engineer.

Toronto, Ont.—Tenders will be received by the Chairman Board of Control, City Hall, up to Tuesday, May 9th, 1916, for the supply of two gasoline-driven diaphragm pumps. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Sherbrooke, Que.—Tenders will be received until April 29th, 1916, for a power pump of the capacity of four million Imperial gallons per twenty-four hours; also a vertical water wheel, flume, shaft, brackets, etc., to operate the above-mentioned pump. Specification and plan can be seen at the office of City Engineer Tremblay, Sherbrooke, P.Q.

Regina, Sask.—Tenders for glass insulators, boppings, connecting sleeves, Cross arms, galvanized iron wire, pole line hardware, steel strand wire, anchor rods will be received until May 6. Specifications, form of tender and all information may be obtained on application to the Department D. C. McNab, Deputy Minister, Department of Telephones, Regina.

Toronto, Ont.—Tenders, addressed to the secretary-treasurer of the Board of Education, will be received until Thursday, April 27th, 1916, for ornamental iron fencing, Roden School, and also for supplying linseed oil, turpentine and sundry material for painters' work. Specifications may be seen and all information obtained at the office of the superintendent of buildings, City Hall, Toronto.

Ottawa, Ont.—Tenders for submarine cable will be received at this office until Monday, May 15, 1916, for 10 knots of single conductor submarine telegraph cable (107 lbs. copper and 150 lbs. gutta percha per knot), with sheathing of 12 No. 8 S.W.G. iron wires, to be delivered at Halifax, N.S. Specification and forms of tender can be obtained on application to the office of the general superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa.

Toronto, Ont.—Tenders, addressed to the Secretary-Treasurer, Board of Education, will be received until April 27, for the following trades, for completion of Administration Building, College street: Ornamental iron work, spiral stairs, iron railings, etc., leaded lights, elevator, ash hoist, vault doors, hardware trimmings, also temperature regulators for Dewson street school; cabinet work, plumbing and electrical work, Lee school. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto.

Personal

A. J. Randall, formerly manager of the Saskatoon Iron Works, Saskatoon, Sask., has gone to Winnipeg, where he will take an officer's course.

J. Quail, formerly sales engineer of the Manitoba Bridge and Iron Works, Winnipeg, has accepted a position with the Canadian Bridge Co., of Walkerville, Ont., as manager of their Winnipeg office.

William Southam of Hamilton, Ont., has resigned his position as director of the Steel Company of Canada. Mr. Southam was one of the original directors of the company and has been closely associated with the steel interests of Hamilton for twenty years.

Dr. William Frederick King, chief Astronomer of Canada and Commissioner for the Survey and Marking of International Boundaries, died on April 23, at the Observatory residence, Ottawa, Ont. The late Dr. King was born at Stowmarket, Suffolk, England, 62 years ago, coming to Canada with his parents eight years later. He entered the service of the Dominion Government in 1872 as Assistant Astronomer on the North American Boundary Commission, and became Inspector of Surveys for the Dominion in 1881. He was made Chief Inspector of Surveys in 1886 and Chief Astronomer of the Department of the Interior in 1890.

Building Notes

Toronto, Ont.—George Kerr has made application to the City Architect for permission to erect a two-storey brick building at 108 Nassau Street, to be used as a dairy. It is estimated that the cost of the building would be $5,000.

Wood-Working

Lindsay, Ont.—Reeve Tiers' planing mill at Fenelon Falls was completely destroyed by fire on April 18. There is no insurance.

Stratford, Ont.—The McLagan Furniture Mfg. Co. propose building an addition to their factory at a cost of about $30,000.

Contracts Awarded

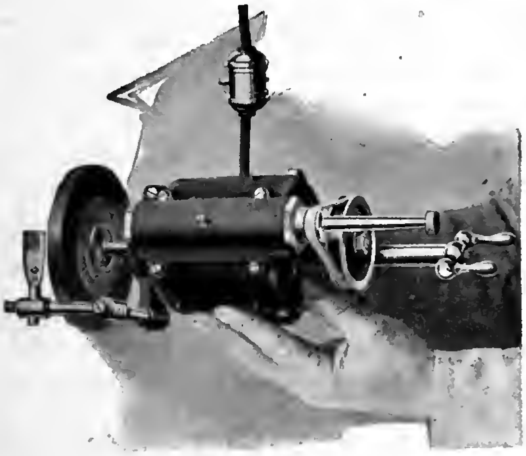
Galt, Ont.—The Galt Foundry Co. has been awarded a contract for the supply of castings by the City Council.

Saskatoon, Sask.—James Priel has been awarded a contract for the extension to the power house at $9,882.

Railways—Bridges

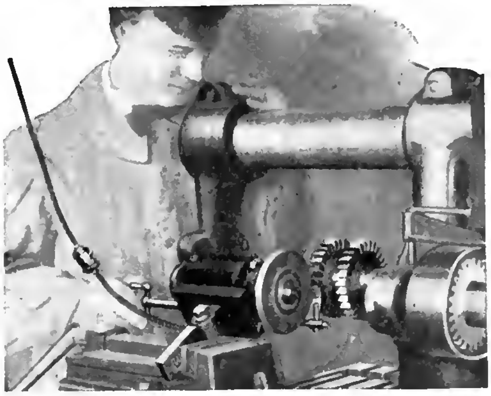
The Pas, Man.—Steel laying on the Hudson Bay Railway will be resumed on May 1 from mileage 242. The steel cantilever bridge at this mileage was completed to-day and trains will be operated over it shortly. There is a demand for railway laborers and 1,000 men are required to carry on the season's construction programme.

Aikenhead's DUMORE GRINDER



The DUMORE Portable Grinder. The only small grinder giving wheels the correct surface speed. Speed, 30,000 R. P. M.

This GRINDER has become known as the most **efficient** portable grinder. Wherever there is grinding to be done it is as valuable as the services of one or two extra men. The DUMORE does all kinds of grinding, longitudinal, cylindrical, internal and other hard-to-get-at jobs. It is equipped with a rest for grinding cutters, enabling the operator to grind his cutters right on the Miller Arbor, whether angular, straight or spiral.



A rapid, practical way of grinding milling cutters.

The best way for you to know how much the DUMORE Portable Grinder will mean to you will be to try one out. Let us ship you a DUMORE.

Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off —DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1¼"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops.

The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

Trade Gossip

The Lauzon Engineering Co. has increased its capital stock to $150,000.

The Berlin Machine Works has changed its name to that of P. B. Yates Machine Co., Ltd.

The Govan Motor & Machine Co., of Govan. Sask., has recently been incorporated with a capital of $20,000.

The Canadian Western Zinc Smelting Co., of Calgary, Alta., has been incorporated with a capital of $1,000,000.

Hamilton, Ont. — If the proposed coke plant is established, there is a possibility of the International Nickel Refining Co., also building a plant here.

Halifax, N.S.—At a meeting of the shareholders of the Nova Scotia Car Works, held recently, it was decided to sell the entire plant. The Eastern Trust Co., of Halifax, are the liquidators.

United States Steel—Official denial is given to reports which recently have been current to the effect that the United States Steel Corporation had abandoned its plans to erect a large new plant at Ojibway, Ont.

Newfoundland Prosperous.—A preliminary statement on the Colonial budget, issued at St. John's, Nfld., on April 20, indicates that Newfoundland is in the strongest financial position in the colony's history. Officials estimate that there will be a surplus of $60,000 for the fiscal year ending in June next, and that the next year also will show a large surplus, notwithstanding the loss of $250,000 in revenue, which will follow the going into effect of the prohibition law next January.

The Panama Canal was reopened to traffic on April 15, with the passage of sixteen ships, seven northbound and nine southbound, including the transport Buford. The channel through Culebra cut was in excellent condition and the passage of the vessels was without incident.

Increase Price of Rails.—The United States Steel Corporation announced on April 14 that after May 1st contracts placed for Bessemer and open-hearth steel rails for delivery after May 1, 1917, will be at the rate of $33 a ton. The present price of $28 a ton has prevailed for thirteen years.

The Canadian Hoskins Ltd., of Walkerville, Ont., makers of gas and oil furnaces and pyrometers, have opened an office at 526 Traders Bank Bldg., which is in charge of Geo. F. Sheppard. The company also announce that the Montreal office has been moved to larger quarters at 224 St. James street.

W. W. Wells, 370 Victoria Street, Toronto, recently supplied the Taylor-Forbes Co., Guelph, Ont., with a 2,000 ampere generator for their electro-plating department. The machine is of the two and three wire type combined, and can be used on either system without alteration to the machine terminals.

Ontario Commission Named.—The personnel of the Provincial Commission appointed to secure the organization of the resources of the province for efficient co-operation with the federal authorities in the prosecution of the war, and the maintenance of the agricultural and industrial production is: Sir John Hendrie, (chairman), Premier Hearst, N. W. Rowell, Hon. J. S. Duff, Hon. T. W. McGarry, Hon. G. Howard Ferguson, C. M. Bowman, C. A. Gillespie, S. Ducharme, W. D. McPherson and Dr. Forbes Godfrey.

War Orders Come to Canada.—The announcement was made on April 19 that since the establishment of the credit of $75,000,000 for the British Government in Canada by the chartered banks, at the instance of the Government, $80,000,000 worth of orders for munitions and supplies have been placed in the Dominion by the Imperial authorities. Sir Thomas White announced on March 15 last that the credit for the British Government had been provided as a result of an offer made by the Canadian Bankers' Association, on behalf of the banks, after conferences between himself and that body which had extended over several weeks.

Merchant Marine Advocated.—Col. Thomas Cantley, president of the Nova Scotia Steel & Coal Co., delivered an address before the Canadian Manufacturers' Association in Montreal on April 19, in which he urged the building of a Canadian merchant marine in Canadian yards, by Canadian steel, and to be manned by Canadian sailors. He declared that since the war broke out Canada had captured part of the heavy casting trade of the Clyde, which was formerly held by the Germans. Many of the big shipping men of the port were present and expressed complete sympathy with the views of Mr. Cantley.

Railroad Earnings Increase.—Aggregate earnings of the three big Canadian railroads in the second week of April show one of the largest gains of the year to date, $1,241,047, or 40.9 per cent. This compares with an increase of $1,083,166 or 33.5 per cent. in the first week of the month. The total of the week was slightly lower at $3,294,907 than in the first week, but as noted the increase over the corresponding period a year ago was larger. The C.P.R. return was the feature, earnings topping those of the first week of the month, while Grand Trunk and C.N.R. figures were slightly lower.

The Canadian China Clay Co., which was formed for the purpose of developing the kaolin deposit in Amherst township, Quebec, is now applying for a Dominion charter, the capital of the company to be $1,500,000. Laboratory tests carried out in France, the United States and Canada, it is claimed, have demonstrated that the Canadian clay, in addition to high ceramic value, possesses all the characteristics necessary for the manufacture of the highest grades of paper and of certain paint pigments. J. C. Braderick is managing director of the new company and among others interested are Sir Wm. Mackenzie, Sir Donald Mann, Andrew Shearer and A. G. Gardner.

U. S. Zinc Production.—Production of zinc ores in the United States for the first quarter of the current year has been 168,669,204 pounds, valued at approximately $8,500,000, compared with an output of 125,693,811 pounds sold for $3,636,155 in the first three months of 1915. Lead output for the three months has been 25,755,574 pounds, valued at $1,096,735, as compared with 18,840,200 pounds sold for $443,303 during the first quarter of last year. At present rate of production, value of this year's output of zinc and lead ores in Joplin district will exceed $40,000,000, as compared with last year's record-breaking figure of $26,000,000.

New Incorporations

The Alexalite Company has been incorporated at Toronto with a capital of $40,000 to manufacture electrical light fixtures and appliances. Head office, at Toronto. Harry Rohleder of Toronto is attorney.

W. H. Banfield & Sons has been incorporated at Toronto with a capital of $150,000, to take over as a going concern the machine tool manufacturing business carried on by W. H. Banfield & Sons, of Toronto, Ont.

Fowler Machine Works, Ltd., of Vancouver, B.C., has been recently incorporated with a capital of $10,000, to carry on the business of ironfounders, mechanical and electrical engineers, brassfounders, boiler-makers, etc.

The E. J. Longyear Company has been incorporated at Toronto, Ont. with a capital of $30,000 to develop and operate mines and mineral deposits. Head office, Sudbury, Ont. William E. Smith of Sudbury, Ont. is the attorney.

The Mutual Elevator Co., with a capital stock of $500,000 and head office in Winnipeg, has been incorporated. F. H. Bole and D. H. Bole, of Fort William, J. T. Haig, A. A. Adams and J. Keelan, of Winnipeg, are the provisional directors.

The Garlock Walker Machinery Co., Ltd., has been incorporated at Toronto, with a capital of $47,500 to manufacture and deal in machinery. Head office in Toronto, Ont. Incorporators, James W. Bicknell and William C. H. Swinburne of Toronto.

The Doyle-Dennert Tractor Co., has been incorporated at Toronto with a capital of $150,000 to manufacture farm tractors and motors, etc., at Essex, Ont. Incorporators, W. C. Doyle, William Nesbitt and G. W. Doyle all of Essex, Ont.

The Canada Boxboard Co., has been incorporated at Ottawa with a capital of $1,000,000 to manufacture cardboard and other products of pulp. Head office at Toronto. Incorporators, George Macbeth, George R. Sproat and F. M. McDowell all of Toronto.

The Hayes Wheel Company of Canada has been incorporated at Ottawa, Ont., with a capital of $200,000 to manufacture automobiles and motor truck wheels etc., at Chatham, Ont. Incorporators, R. H. Parmenter, A. Thomson and William S. Morloch all of Toronto.

The Joliette Steel Co., Ltd. has been incorporated at Ottawa, Ont. with a capital of $100,000 to manufacture

steel, iron and other products. Head office, Montreal. Incorporators, James K. Stinson, Ernest V. Moore and E. Lorne Stinson all of Montreal.

The Bournonville Rotary Valve Motor Co., Ltd., has been incorporated at Ottawa with a capital of $500,000 to manufacture mechanical and electrical appliances. Head office at Toronto. Incorporators are W. Gilchrist, J. Stewart and H. J. Stewart all of Toronto.

The Menard Motor Truck Co. Ltd., has been incorporated at Ottawa with a capital of $250,000 to manufacture motors and other vehicles at Windsor, Ont. Incorporators, W. N. Gatfield of Sandwich, Ont., Fred Hurst Neal and William H. Neal both of Windsor, Ont.

The Barton Feeders Co., of Hamilton, Ont., has been incorporated to manufacture furniture, nails, horse shoes, machinery, tools, vehicles of all kinds, etc., $40,000 capital, by Hugh J. McKenna, Leewellyn F Stephen, William J. Lord, and others all of Hamilton, Ont.

The M. F. P. Aeroplane Ltd., has been incorporated at Ottawa, Ont., with a capital of $500,000 to manufacture all kinds of aeroplanes, hydroplanes, etc., Head office at Toronto. Incorporators are W. Gilchrist, James Stewart and Hamilton James Stewart all of Toronto.

The John Dixon & Co., a corporation created under the laws of Great Britain, has been granted a license to manufacture machine rules, hot presses, glazers, etc., $40,000 capital stock; Reginald G. Allder, of Toronto, Ont., has been appointed attorney.

The Homo Chocolate Creamery Co. has been incorporated at Ottawa, Ont., with a capital of $100,000, to manufacture all kinds of products in which chocolate, cream or milk forms the principal part. Head office at Montreal, Que. Incorporators: F. Monnette and G. Roberts, of Montreal, Que.

The Louden Machinery Co. of Canada, Ltd., has been incorporated at Ottawa, Ont., with a capital of $250,000, to manufacture machinery, barn equipment, hay tools and implements, etc. Head office at Guelph, Ont. Incorporators: James E. Day and Joseph P. Walsh, of Toronto, Ont.

The Dominion Cutlery Co., Ltd., has been incorporated at Ottawa, with a capital of $100,000 to carry on business as manufacturers of cutlery, plated ware and articles made in metal. Head office at Montreal, Que. Incorporators are, M. A. Phelan, A. Lafontane and Harry L. Coombs all of Montreal.

The Dominion Sugar Co., Ltd., has been incorporated at Ottawa, Ont. with

a capital of $5,000,000 to carry on business as sugar manufacturers, etc. Head office, Wallaceburg, Ont. Incorporators, Henry B. Smith of Bay City, Mich., Charles H. Honson and Herman Weise of Wallaceburg, Ont.

The Canadian Steel Specialty Co., has been incorporated at Toronto, with a capital of $100,000 to carry on a general steel manufacturing business and to manufacture every description of iron and steel. Head office, Grimsby, Ont., Incorporators, Harry George Hess, and Jesse H. Foster of Grimsby, Ont.

Catalogue

"Waterproof Graphite Grease" is the the title of a new 16 page booklet gotten out by the Joseph Dixon Crucible Co., Jersey City, N.J. This valuable little book explains fully, in a concise and clear way how many difficult lubricating problems have been overcome. It also deals with the care and up-keep of heavy, slow-moving machinery and parts that are exposed to unusual wear. Some of the subjects treated are lubrication of elevator plungers, the best way to handle wire rope, open gearing, dredging machinery, and rolling mill lubrication, the lubrication of sugar rolls, pulp and paper machinery. A copy of this booklet will be gladly sent to anyone interested.

Book Review

The Canadian Mining Manual for 1915, edited by Reginald E. Hore, and published by Mines Publishing Co., Toronto, Ont. This manual, as in previous years, contains a great deal of interesting and useful information, covering the mineral production and mining industry of Canada. One of the main objects of the publication of this book is to carry into other countries reliable information concerning the minerals and mines of Canada, at the same time it serves as a record for those interested in the subject in this country. The manual is arranged in five sections. The first covers a review of mining in Canada in 1915, while the second deals with mine products, and includes a description of the various minerals found in Canada and method of treating the ores. Section three consists of a review of the mineral production in each of the various provinces, written by reliable authorities. Particulars of the mining companies operating in Canada are given in section four, while section five gives Canadian mining companies listed according to product. The manual contains over four hundred pages and is bound in attractive red cloth covers.

Machining and Assembling the Military Rifle Bayonet

By F. H. Mayoh

Bayonet manufacture, like that of shells, has been both war-initiated and war-stimulated, although as far as we are concerned the latter has demanded and monopolized the full extent of our metal-working plant activities. Bayonet production, it will be noted, is quite distinct in its operation features from that of shells; as a result our readers will find in the accompanying articles a welcome diversion, besides obtaining at the same time a further insight into the manufacture of another and highly important piece of the individual soldier's equipment, offensive as well as defensive, and particularly effective in either case.

Bayonet manufacture presents to the machine shop an entirely different proposition from the general run of war implements inasmuch as the operations required are chiefly milling, while those on other munitions are largely turning. The usual impression which a bayonet conveys, apart from its cutting qualities, is the case with which it is attached to the rifle, and by referring to Fig. 1 this point is clearly brought out.

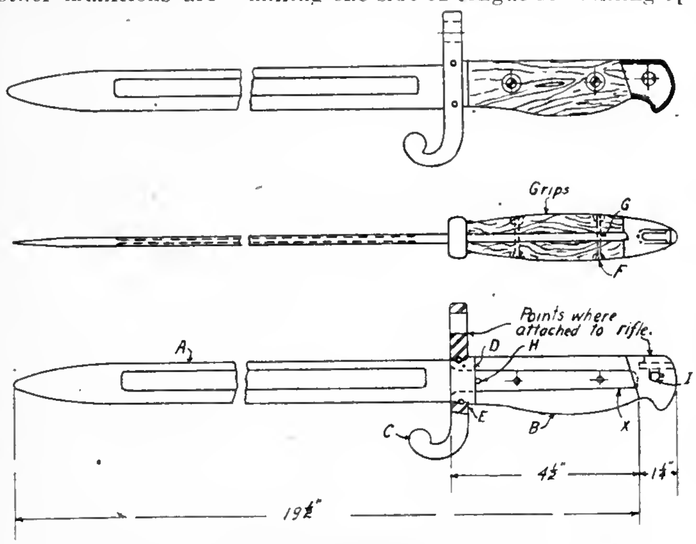

FIG. 1. DETAILS OF BAYONET CONSTRUCTION.

Construction

These convenient weapons for close combat are made in three main steel parts, the grips and a number of smaller pieces. The blade, A. is made from a good grade of tool steel, and is drop-forged from the bar. The hilt, B, and guard, C, are mild steel forgings and are practically machined all over. The two grips are of black walnut, while the other fittings are from commercial stock with such exceptions as are later described.

The commercial bayonet is a highly finished product, well made and conveniently assembled. The end of the blade is tapered to fit between the prongs of the hilt at X, while two plates, D, pin these prongs together. The guard fits over these plates, and two pins, E, are used to hold the guard in place. The grips are held in place by special nuts, F, and studs, G, while the bayonet blade is prevented from pulling out of place by the pin H. The lock for holding the bayonet to the rifle barrel is shown at I, which is assembled with a bushing and a spring for operating the lock while putting the bayonet in place or removing same.

As the blade of a bayonet is the one essential feature about which the rest is built, it will be considered first. This is made from a good grade of tool steel rough forged to the shape shown at A, Fig. 2, and is finished, mostly by milling, to the shape shown at B.

Nature of Operations

The operations on the blade consist of milling one side of tongue A—milling opposite side of tongue B—mill back edge of blade C—mill front edge of blade D—mill back edge of tongue, straight and taper E—mill front edge of tongue, straight and taper F—mill end of tongue on radius G—mill groove, one side H—mill groove opposite side I—mill back taper of one side K—mill back taper opposite side L—mill cutting edge M—mill cutting edge N—drill the three holes—mill out corners in grooves—grind point and cutting sides to shape—harden and temper. Throughout the machining on these blades, gang milling fixtures and cutters are used quite extensively as production is quantities is an important consideration, and further, the machining operations are required largely for retaining the high qualities of the steel, which would be lost in forging to a fine edge unless very carefully done.

Referring to Fig. 3, the fixture for milling the side of the tongue is shown. In this tool the work is set upon a steel seat at A, located against the block B by the point of the blade; a sufficient number of blades being placed in the fixture to take up the complete travel of the table. The blades are clamped two at a time by expanding jaws, C, against locating seat, D. Under the free end of the blades, spring pins, shown at E, are used to steady the work. The cutters used are a gang of two which feed in the direction of arrow and cut the step shown.

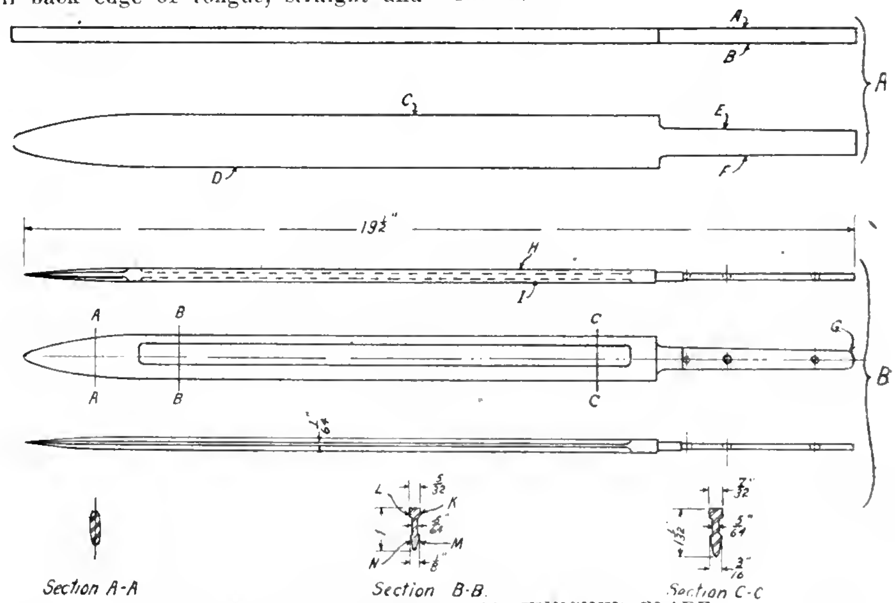

FIG. 2. (a)—ROUGH FORGING. (b)—FINISHED BLADE.

For milling the other side of tongue a similar fixture is used with the exception that instead of turning the work over in

the natural manner, it is turned over end for end as shown below in Fig. 3, thus bringing the points of location on the tongue in the same place on both fixtures, although the fixtures will be left and right hand.

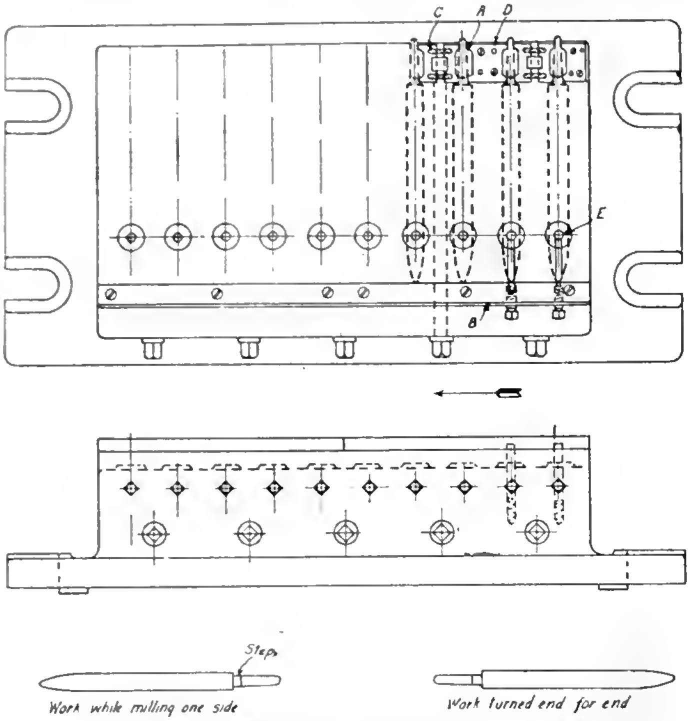

FIG. 3. FIXTURE FOR HOLDING BLADES WHILE MILLING SIDES OF TONGUE.

To mill the back edge of blade advantage is taken of the tongue just machined for holding the work by jaws A, Fig. 4. The blades are here set upon the seat B, while jaws C are held against the sides of the blades by means of springs D to support them against the cut, these strips being locked by the screws E while taking the cut. The jaws A which grip the tongue are positive and are locked by a tapered bushing F and screw G, it being necessary to clamp with these jaws before tightening the spring jaws as the work is thus located.

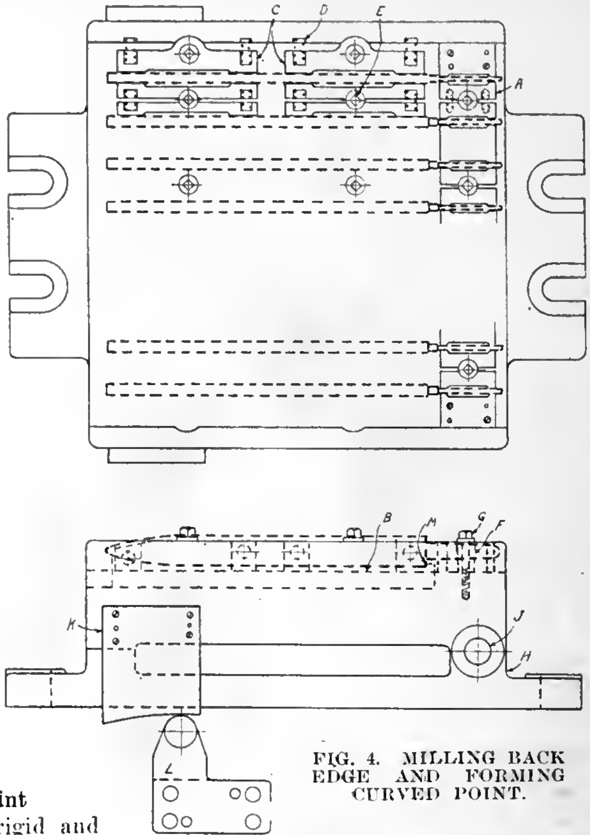

FIG. 4. MILLING BACK EDGE AND FORMING CURVED POINT.

Milling Curved Point

This provides a very rigid and effective means of gripping the blades while edge milling, but one thing which must be included in this fixture is the means of milling the curve at point of blade. This is accomplished by setting the fixture on a sub-base H, and allowing it to pivot at J, when by placing a formed block at each side of fixture K and mounting suitable blocks, L, on side of milling machine table knee, the fixture will ride over the blocks and cause the cutter to form the curve at point of blade. The front edge of blade is milled in the same manner, using locating blocks to fit the form at back of blade just finished, the location endwise in both fixtures being obtained by the curved end forcing the blade against the shoulder of the tongue M.

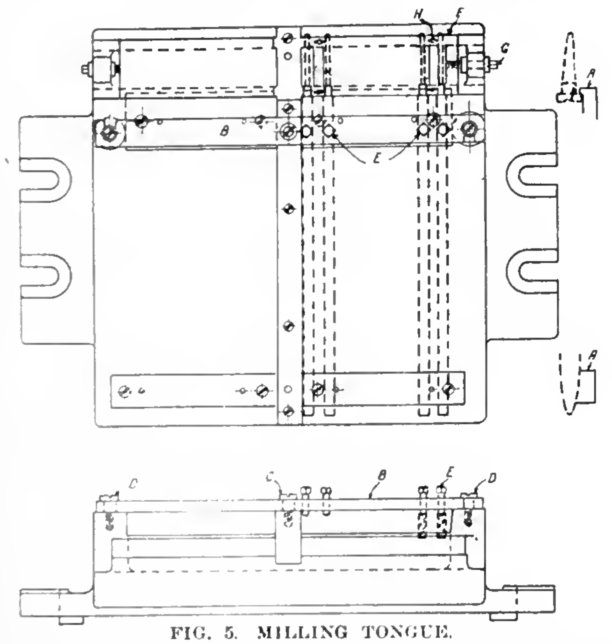

FIG. 5. MILLING TONGUE.

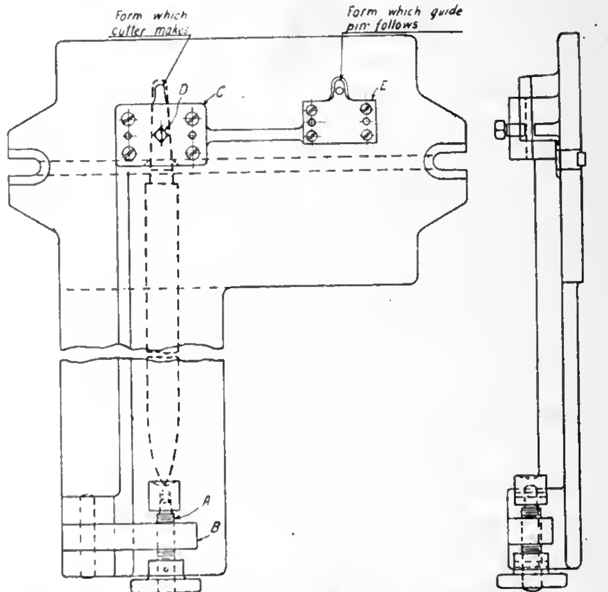

FIG. 6. FIXTURE WITH FORM FOR PROFILING END OF TONGUE.

To mill the back and front edges of tongue, including the straight and tapered portions, the blade is seated on the edges, with a swing block which carries screws, to hold the work down, while the gripping is done by blocks which bind the sides of tongue. For this purpose a

fixture shown at Fig. 5 is employed. The work is located against the block A, and is clamped by the screws E. These screws are placed in the swing block B, which pivots on the stud C and hooks under the screws D. The tongue of the blade is clamped by the block F, which is adjusted through the screw G. The screws shown at H hold the locating blocks in place and the holes for these screws are elongated to permit the blocks to float for taking up the variations in the thickness of the tongue, although these tongues are held very close to standard size.

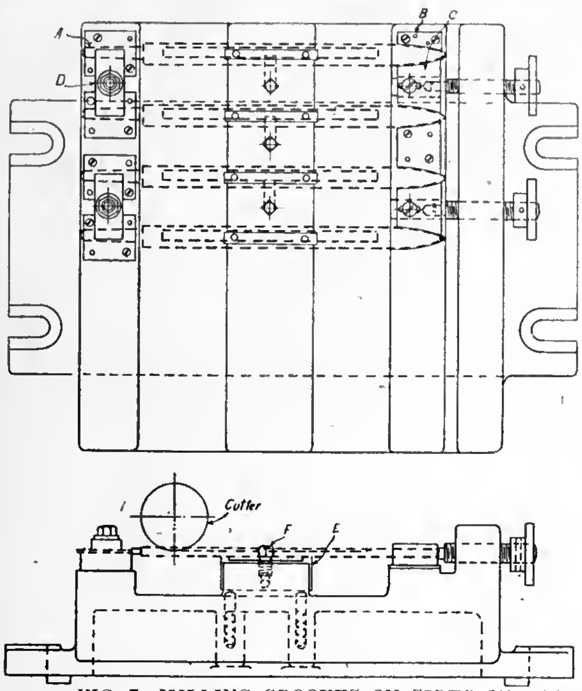

FIG. 7. MILLING GROOVES ON SIDES OF BLADE.

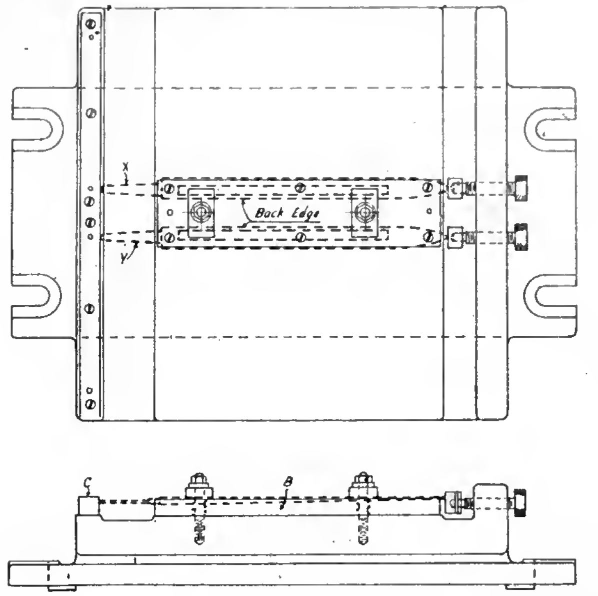

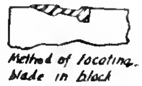

FIG. 8. LOCATING BLADES FROM BACK EDGE WHILE MILLING CUTTING EDGE.

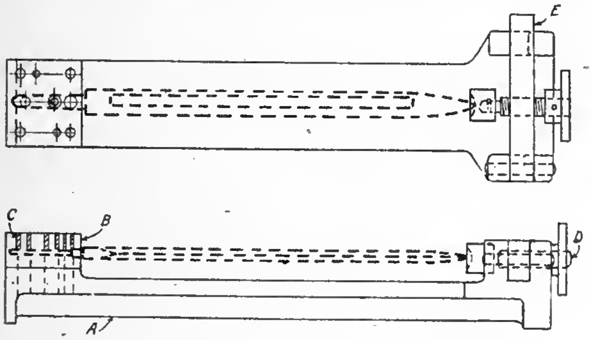

FIG. 9. DRILL JIG FOR HOLES IN TONGUE.

Profile Milling

All of the fixtures so far described are

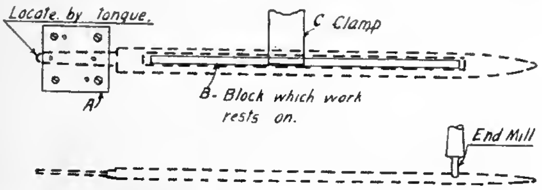

FIG. 10. METHOD OF MILLING OUT CORNERS IN GROOVE

for gang milling. The next fixture, Fig. 6, for machining radius at end of tongue, is a profile milling fixture for handling one piece at a time, and is simple to operate, although requiring the constant attention of the operator. In this profile milling fixture the screw A is held in swinging piece B, and is swung clear of the point of blade, the tongue of the blade being slipped into block C, and screw A locating it in the position shown. The screw D securely holds the blade in place. The formed block, E, has the same curve as the end of the tongue and is for guiding the pin which governs the form the cutter will make, as the operator feeds the to make the cut.

Milling the grooves is another operation where gang milling is used to good advantage, although an extra cut must be taken to remove the corner left by the cutter. The fixture used, shown in Fig. 7, provides for locating the work by the tongue in block A. It is clamped against the formed block B by wedge C at point end, and is clamped on top of tongue with strap D, one clamp and one wedge being used to grip two pieces in their respective positions. For taking the downward spring of the work under the cut, spring blocks are used under the rough side and clamped by screws F. When one groove is finished the blade is prevented from springing under the cut by a fixed block in place of the springs and floating block. In this operation it is necessary to raise the table to commence cutting and to lower the table to remove the work. When milling back taper K and L, Fig. 2, a fixture similar to the foregoing with a block in under side groove to prevent spring of blade is used, the block being tapered to bring point end of blade higher than tongue end which causes the blade to be milled taper.

Forming the Cutting Edges

To mill the cutting edges, reference is made to Fig. 8 where both sides of the cutting edge are milled in the same fix-

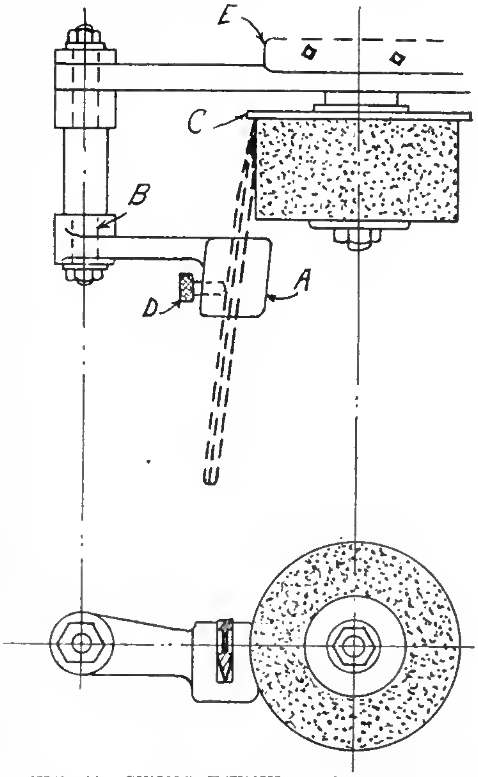

FIG. 11. SWING FIXTURE FOR GRINDING POINT.

ture, the blades being placed in pairs, X and Y, back to back with a clamp between them; the blades being set in the fixture on the blocks B, which fit the

groove and back taper previously machined. The back edge locates the blade lengthwise and the thrust of the cut is taken by the end of tongue against block C. The blades in this case are tipped in two directions to give approximately the compound angle necessary to obtain the dimensions as given on the section shown by Fig. 2.

Drill Jig

With the exception of one minor but necessary operation the milling is now complete, and the next operation is to drill the three holes in tongue, using the simple jig, Fig. 9. This jig consists of the base A and cap B, into the latter of which is cut a form to receive the tongue of bayonet. The three guide bushings for the drills, C, are contained in the cap. In operation, the screw D, held in block E, is swung clear and the work slipped into position with the screw holding it in place and the drilling is then accomplished in the usual manner.

Fig. 10 illustrates the method of milling out corners in groove, the locating points only being shown. The tongue is placed in block A, the blade resting on block B in the groove, on under side, and a clamp C binds the blade on top while cutting. This operation is done by vertical milling cutter in the form of a small end mill, the manner of using being obvious, as this tool cleans out the radius left by Fig. 7.

Grinding the Points

There now remains to be machined the point of the bayonet blade and a slight amount of finishing on the cutting sides. This is taken care of by grinding with the assistance of simple attachments for the grinding wheel. For grinding the point the blade is set in holder A, Fig. 11, and the latter is made to pivot at B. The point of blade is held lightly against a disc, C, mounted with grinding wheel, and is clamped in position with screw D. By swinging blade on pivot B the point is ground on a radius which tapers back to shape. The holder is adjustable at E to allow for wear of the grinding wheel.

When grinding the cutting sides the blade is passed back and forth across the face of the wheel with a slight twisting movement which gives the desired shape and completes the machining of the blade.

The making of this bayonet blade gives a good illustration of economical handling of a long slender bar of a complicated nature on the milling machine, one of the chief difficulties to overcome being the spring of the work, and as it has been necessary to dwell at some length on this part, the machining of hilt, guard crossing, and assembling will be taken up in another article, the assembling of the bayonet being treated in its relation to assembly or use with the rifle.

TURNING OUT CHEAP CASTINGS

IN foundry work, says the Foundry Journal, two classes of castings have generally to be turned out—those which have to be made of the best quality and to stand high tests irrespective of cost, and those which have to be produced at a moderate cost, and which have to undergo no tests, but which merely have to be sound. Possibly both classes may have to be made in the same foundry, but more generally this is not the case where castings are made by engineering works running their own foundries, as such places always specialize more or less.

Class of Castings Feature

When laying out a place where cheap output has to be dealt with, the class of castings produced will need consideration and this because there are means of reducing costs very considerably. Thus the use of moulding machines, false backs in hand moulding, and other things of this character cheapen labor in the making of moulds, while a coremaking machine reduces the cost where large numbers of cores of stock sizes are required. Besides such appliances as these there are also different things in regard to the sifting, mixing, and grinding of sand, carefully made flasks, and other items, tending to save time, so that having in view the class of work which is to be produced, by a suitable selection of the tools used in working, large savings can be made in the cost of the mould production.

As wages are a very important item in all classes of foundry work, it is equally important that everything should be done to make patterns and other details favor the moulder, because in many places more time is spent in mending and patching broken moulds than in their actual production, and this simply because the make of the patterns prevents a clean lift or draw being secured. The making of one or two extra flasks per day means a large reduction in cost of production, particularly where light castings are being dealt with.

Pattern Upkeep

Another point is to keep all patterns in good condition and well varnished, so that they do not suck the sand, for it will be found that, in all but exceptional cases, moulders appreciate good patterns. Apart from labor charges, fuel has to be considered, and a good foundry coke free from an excess of sulphur is cheaper than gas coke in crucible melting, because there is less weight per part of metal used on the one hand; again, crucibles burn out less on the other, sulphur being bad for plumbago crucibles.

Scrap Metals

Generally speaking, scrap metals would be used for cheap castings, and by careful sorting almost any class of castings can be produced. Take iron, for instance:—If galvanized stuff is kept out, rough scrap bought from itinerant collectors will take in everything from old machinery to soft iron, and from hard and burnt stuff to old saucepans and the like, some of the older material being good as new pig.

Brass and gunmetal, taken unsorted from the dealers, may be bought on an average far below what new metals would cost, and by careful sorting almost any class of castings can be produced. Even such stuff as small turnings, at a price, comes in well, but, of course, it is desirable that it should be passed through a magnetizing machine to remove iron. A good sorter will make a variety of qualities from a heap of mixed stuff, and will enable one to turn out almost any kind of cheap casting needed, even the poorest qualities having use. It generally happens with cast brass scrap that a fair proportion little better than brazing spelter is present; it may, therefore, usually be assumed that zinc is in excess. For this reason it is necessary to run down large crucibles where this is sorted out separately, and to use the metal for the lowest-priced castings. For the better work the rolled scrap will come in well.

Old-fashioned house bells should always be saved, as owing to their richness in tin, they work in well with gunmetal, provided they are not too freely added. As a matter of policy it is always well to use some good make of deoxidant flux with all scrap metals, because there is the ever-present risk of having paint or other objectionable foreign matter present with some part of the charge, and this may very well cause porosity. New metal should cast clean enough, but scrap is often awkward to deal with unless outside assistance is provided.

PROCESS OF COLD ENAMELING

THERE are many small objects whose beauty is much enhanced by the application of a coat of enamel, but which are not capable of being fired. A process of enameling these in the cold, so simple as to be quite practicable, is described in La Nature as follows: To a solution of sodium silicate, boiled in a closed vessel, there is added about 5 per cent. of sulphate of lime. This causes a precipitation to take place, the ulterior effect of which is to prevent efflorescences which would injure the looks of the enamel. The solution, after being once decanted, assumes the consistency of a paste which is heated to about 75 deg. C. to apply to the objects to be enameled. A second decantation takes place in the vitreous layer, and this then takes on an unalterable translucence. It may be tinted any desired shade, either in the mass or superficially, the colors being fixed by tannates of gelatine and alum.

PIECE WORK SYSTEMS—I.

By R. R. Clarke.

THE economic principle of factory operation sanctions nothing that does not favor increased output at reduced expense. Every practice or change of practice in the system of all systems can be traced to this actuating desire. "More for less" seems to have been the slogan of the masters from the earliest dawn of the labor question down to the present and has been answered by the murmur "too much for too little already," from those whose lot it has been to serve.

While the world lasts, some will work: others be worked. Nor does this mean that any one class or either side has been doing all the work or suffering all the woes of the "being worked" class. Bright men sit at the desk but those just as bright work at the bench. Between them it is a big game of checkers, each side studying the board and planning its move, wondering all the while what the other fellow is going to do next. For this, corporation interests have banded and met their resistance in the unions of men; on the one side brains: on the other brains and brawn. Time has passed when trickery gains much. Something higher in principle, more honorable in conception must be substituted. Employer and employee must meet on grounds congenial to both. Advantages must be mutual or the party on the long end of the business chuckles while the other fellow kicks and squeals.

Piece Work an Equalizer

The piece-work system is in part a solution of the problem. In the foundry it is of special advantage. That it entails some evil we have no doubt, but that it yields benefits far in their advance we have as little doubt.

The most praiseworthy feature of a good piece-work system is that it places every man on his own resources and stamps him for exactly what he is worth. To the employer it offers increased production and protection against the careless, lazy, or indifferent workman, while it yields to the workman the advantage of increasing his daily earnings and applying his aptitude to his own profit. Yielding this dual advantage it appeals with reasonable attractiveness to both sides and offers a respectable avenue of escape from more than one difficulty.

It is, however, not without its difficulties. The setting of piece-work prices has a tendency to call forth many contentions between the foreman and the workman. In this the foreman's lot is, indeed, a hard one. Having his own conscience, the firm and the workman all to satisfy, his position is not always an enviable one. Determining bad work and fixing the blame therefor often brings coremaker, furnace-man, helper, moulder, foreman and inspector together in stormy seance. The system often superinduces in the man a tendency to dishonest practices, which from both a moral and business standpoint is a serious thing. It also favors development of a class of inferior workmanship due to what for want of a better we shall name the "hogging" instincts of the man. In fact our experience in this has been such as to strengthen the opinion that piece-work moulders are inclined to make castings just good enough to pass and very often insist on having their own judgment decide the issue.

Their disadvantages, however, all lie within the province of elimination, or at least satisfactory adjustment. That some have failed to realize such and decry the system in consequence is no conclusive evidence against it.

Necessary Conditions

We believe in the piece-work system, the equitable adjustment of piece-work prices and reasonable demands for high standards of workmanship in the absence of which the casting is scrapped and the workman at fault made to suffer the loss. We favor piece-work prices that will enable the honest and average workman to increase his daily earnings at least 25 per cent. over the day-work figure, such increase carrying with it the demand for nothing but merchantable castings. We believe in a just and trustworthy inspectorship, an equitable and competent inquiry into all circumstances and conditions to which the loss of the casting may possibly be traced, and the closing of all arguments with the decision that good judgment derives therefrom. At the same time we maintain that no workman should be made to suffer any loss arising from an error of judgment on the part of the management and deem no man fit for management who, to cover up his own error, would attempt to cast reflection on the workman, or attribute the loss of the castings to any other cause. That such a system will meet with opposition at its inception is a foregone conclusion, but a firm yet courteous determination will bring harmony out of discord and work benefits for all.

HEAT TREATMENT OF COPPER ZINC ALLOYS

By "Melter."

COPPER zinc alloys are generally considered by taking up the theoretical side of the constitution of the alloy which points, when gone into, have little practical value. It is of interest however before going further to note the effect of decreasing the percentage of copper and increasing the percentage of zinc.

Copper content per cent.	Tensile strength tons per sq. in.	Comparative malleability	Comparative hardness	Grain
79.5	15	7	15	Fine
75.0	13	10	14	Fine
66.0	12.5	3	23	Fine
49.5	9.2	12	12	Coarse

If the percentage of zinc is very low it generally will be found that the brass is full of blow holes and therefore unsatisfactory. It is not possible to work brass hot as the tensile strength becomes so low after 400° F. has been reached that the metal tears. In fact brass is so sensitive under shock at higher temperatures, say 1300° F., that if a piece be dropped, it will very likely be found to be defective. The period of annealing does not affect the structure much until 1300° F. has been reached when it has been found to greatly weaken 30-70 brass if held in the oven too long, say longer than 45 minutes.

The most important factor in annealing brass is to anneal at the lowest possible temperature to get the required elongation. Tensile strength increases with annealing temperature up to 550° F. when it falls off with gradual increases in elongation.

Effect of Annealing

If the tensile test pieces are examined when the annealing has been done at a high temperature it will be found that the surface is roughened demonstrating that the grain size is too large and that there are cleavage cracks between the crystals. Microscopic examination shows that at about 750° F. annealing temperature brass begins to have enlarged grains and at 1380° F. the size of grains is about at the maximum allow-

able if any commercial use is to be expected from the product. A glance at the figures showing strengths and elongations at varied annealing temperatures will confirm the above.

TEST OF 30-70 BRASS

Temperature Degrees Fahr.	Maximum Stress tons per sq. in.	Elongation in 2 in. %
...	25.0	15.5
515	28.5	20

Quenching brass has been found to give very little difference except in the elongation but the results obtained do not warrant any adoption for commercial practice. Annealing then should be carried out at from 1200° F. to 1300° F. with a period of 30 minutes at that temperature and great care should be taken to heat uniformly and not to subject the brass to shock or strains at that temperature.

PURCHASING LARGE MACHINERY

IN a paper read before the Mechanical Section of the Engineers' Society of Western Pennsylvania by G. A. Orrock, mechanical engineer, the New York Edison Co., it was pointed out that two methods have generally been employed in purchase of large machinery.

In the first and what has been called the English method, the purchaser's engineer prepares detailed plans and specifications on which bids are taken in the customary way, an award is made and the successful bidder builds the apparatus. He may or may not be responsible for the results. If he is responsible for results, he is usually allowed to vary the details to some extent.

The second method has perhaps been more used on this continent. Here the purchaser furnishes a specification setting forth the conditions of the problem, the end to be sought and certain sizes to be observed. He also specifies an economical performance to be reached and to be guaranteed by the contractor. There may or may not be a bonus and penalty clause for performance, also provision for an economy test. Bids are taken on this specification and an award made. The successful bidder builds the apparatus.

Faults of Both Methods

Both of these methods are faulty. The first leads to excessive cost and the perpetuation of fads, to higher maintenance; the economies as a general rule are not so good as they might be. The second method usually secures a machine not quite fitted for the work, high maintenance and undesirable operating costs, and a set of constructional details adapted from some other type of apparatus. The economies may be up to guarantee and usually are, but the over-all economies are not bettered in the way they should be.

The second method has more vogue here because the control is more largely financial than technical, and the tendency is to let experimenting be done by others. Here the responsibility for design and results is put up to the contractor and the apparatus is never quite up to the state of the art, as he too will not use his latest knowledge to any extent. He will use all the well-tried devices, will make small economies everywhere and meet the guarantees, but his latest knowledge will be reserved for the second or third proposition beyond this one.

Under the first method much good work has been done, but the scrap heap has been enlarged much more under the second method. The chief advantage is secured where the purchaser's engineeer is unhampered in his design, always stipulating that he is a high-grade engineer with few fads and a broad acquaintance with the art.

Combination of Methods

The best results may be secured by a combination of the two methods, bearing in mind that the best engineering is one man's work, although he should have many advisers. The purchaser's engineer prepares a skeleton specification with certain plans and details on which proposals are selected as being the best, and a series of consultations take place in which the entire problem is gone over in an engineering way, with the engineers of each bidder. During these consultations the specifications may have undergone changes and been added to until it is no longer a skeleton, and at the end the selected bidders make their final proposal.

Sometimes only one bidder might be selected, or it might even be found necessary to start all over again. Frequently it has been found necessary to go outside of the regular line of contractors on a certain line of apparatus in order to get the required results, and more frequently improvements and means of economies must be brought to their attention and the adaptability of well-known types of apparatus in other fields suggested to them.

I have known cases where the entire plant was detailed in the engineer's office. A saving of 50 per cent. in the operating cost was attained and similar economies have been reached by using contractors' designs, but these cases are usually exceptional or occur in remodeling old plants. With the combination method economies of 10 to 15 per cent. have been readily secured in first-class plants, being at the time perhaps all the state of the art would allow.

Forcing the Manufacturer's Hand

Manufacturers' representatives frequently say, "We do not care for that kind of business; our shops are full and it upsets our work; we cannot afford to touch it." The answer invariably should be: "You can't afford to pass it by, even if you should take the business at a loss, for some one will take it, and if the economies are sufficient you will have to build it in the end and pay them for the privilege."

The position of the engine-building shops 15 years ago and to-day well illustrates this phase of the subject. It is not, perhaps, too much to say that many of the great steps in the engineering arts have come with the purchasing of large machinery by the last plan. In the early days of the electric-lighting industry Mr. Edison, looking ahead as he always did, designed his largest generator for direct connection to a high-speed engine. The Jumbo units installed at the old Pearl Street Station in New York were the result. Standardization, however, made the belted plant common and almost universal. It was a common practice to put two flywheels on a 500-h.p. high-speed engine, and, running double belt on each flywheel, to connect four 62-k.w. generators to each engine. I am credibly informed that a station with 10 such units was in operation within two years.

Engineering purchasers finally brought the multi-polar machine and the engine into direct connection, which resulted in the so-called heavy-duty type of frame. The use of the centrifugal pump for boiler feeding was forced on the manufacturers, who much preferred to furnish the standard article. Again, in the fields of mining and metallurgy there are many illustrations. The handling of material, cleaning of gases, types of furnaces, introduction of new processes, all bear evidence that this third method has been long used. The early development of the open-hearth furnace, as told by S. T. Wellman, illustrates the taking advantage of the best talent available in the design and purchase of large machinery, and the development of the rolling mill has been the product of both the purchasers and contractors' engineers in consultation.

Conclusions

In this era of change and progress engineers interested in large machinery should keep closely in touch with contractors' engineers and with the state of the art in other industries. The results of a small experimental machine in one industry may set the pace for a great step in another widely different industry.

The purchaser of large machinery must be broad, as is consistent with his knowledge, of judicial mind, reasonably quick in decision and with as wide an acquaintance with the art as possible. Such an engineer will not take up fads, will know within reason what his limits are, and will not be frightened by cost in block, knowing that it is cost per unit of output that counts in the result.

G.T.R. Apprentices at Stratford Shops are Again Winners

Contributed

The object of an apprenticeship system is to provide a supply of well-trained mechanics, foremen, and staff officers who can be relied upon to go ahead with and carry out efficiently and successfully productive work in a particular sphere of manufacturing and industrial enterprise. It has been found from experience that men so trained become not only a valuable asset to those directly concerned, but are an important contributory factor in the matter of that higher standard general competence, so necessary to manufacturing achievement.

IN the Grand Trunk Railway System, and particularly the big shops located in their midst, the citizens of Stratford take a just pride, and the enviable reputation which the apprentices have secured and maintained from year to year at the annual examinations held by the company, bears striking testimony to the capable work of the master mechanic, Robert Patterson, and the local instructor, M. A. Humber.

Thirty-five Don Khaki

The Stratford shops apprentices have 35 of their number on various units of the Canadian overseas forces. Some of them are now fighting in France, doing their bit for the Empire and Canada. Another 35 are engaged on shell work, also doing their bit by helping the boys at the front win their battles. In spite of this drain on their personnel they have again been able to take first prize at the apprentices' annual competition over the entire Grand Trunk System, having obtained the highest average combined marks for drawing and mathematics. For a number of years apprentices at other stations have been unable to wrest this honor from Stratford, and not only do the boys themselves feel proud of their achievement, but all employees at the shops and the citizens generally are glad to know that the boys have again kept their reputation.

Swept the Prize Board

At a meeting held in the Assembly Hall, on April 27, the master mechanic, Robert Patterson, presiding, the boys were congratulated on their success as a class and the three individual boys, named, A. Anderson, 1st year; A. McDowell, 4th year, and W. Davis 3rd year, who took three capital prizes out of the five given for competition for apprentices all over the railroad system. Mr. Patterson informed the apprentices that they were all to receive a substantial increase in their rates. This will enable apprentices who come to learn a trade and have to support themselves, to do so comfortably, and should prove a great incentive for boys to come to the Stratford shops and not only have the advantage of learning a first-class trade in all its parts, but also receive a training in mechanical drawing and mathematics during their apprenticeship.

Graduates Hold Good Positions

Stratford is particularly fortunate in turning out a large number of young

THE APPRENTICE CLASS OF 1915-16, G.T.R. SHOPS, STRATFORD, ONT.

First row (left to right)—W. Hayter, C. Smith, J. Meeks, E. Marks, F. Bowra, A. Wilhelm, C. Wilbee, J. Earnshaw, M. McDowell, C. Gibson, J. Hagarty, G. Richards, J. Gaunt, G. Mellors, A. Jeffries, F. Herod, F. Flaherty, M. Schaefer, G. Grandy.

Second row—C. Shaw, C. Pepper, R. Andrews, T. Durney, S. Devlin, F. Wilson, V. Swansen, F. Rutherford, F. Tuthill, W. Schultz, D. Sproat, A. Keep, F. Mitchell, P. Barclay, R. Ord, C. Hubbard, E. McPhee, V. Murphy, F. Salisbury.

Third row—A. Lewis, W. Krug, F. McIntee, W. Flanagan, G. Barrett, E. House, R. McTavish, W. Edwards, E. Kneitl, J. Blum, A. Townsend, B. Wilson, D. Humphrey, B. Dyer, W. Montgomery, H. Farrow, G. Marks.

Fifth row—J. Flaherty, A. Capper, H. Rowland, L. Day, D. Davis, A. McKenzie, F. Isaac, S. Bruickner, A. Graff, C. King, E. Campbell, E. Wilhelm, W. Grandison, W. Furey.

Sixth row—H. Brayne, R. Sillifant, G. Maynard, — Wilhelm, G. Dinan, W. Keep, T. Pollard, R. Clarke, A. McDowell, A. McPhee, J. Black, V. Copeland.

Seventh row—B. Wilson, S. Tuthill, L. Abbey, G. Allan, F. Given, O. Osborne, L. Dempsey, C. Schellenberg, F. Taylor, A. Fraser.

Eighth row—W. Shaw, R. Huegli, L. Waddell, J. Rutherford, W. Schaefer, J. Wingefelder, A. Dickson, P. Chesney.

Ninth row—H. Jones, G. Gilbert, E. Davis, F. McInnis, H. Schultz, G. Salisbury, J. Day, J. McArdle.

men who are now holding good positions on the Grand Trunk, other railroads, and in manufacturing establishments. The idea actuating the management is to secure the right kind of boys in the first place, then look after them during their apprenticeship. Not only do the apprentices at Stratford receive these advantages, but they also hold a correspondingly good social position in the community.

Value of Industrial Classes

Just here we might mention, the many advantages of the industrial classes at Stratford, which are supported by the Government. Boys who have to leave school earlier than usual and cannot pass the entrance examination to become apprentices in the shops, attend the night classes regularly and receive sufficient education to enable them to enter later as apprentices, large numbers of these being taken on at the works as probationers.

The apprentices have always been accustomed to hold an annual banquet. This is not altogether an affair of pleasure, being usually of an educational nature in addition. These banquets are held at all the large stations on the G. T.R. system, and a couple of apprentices are sent from each station to represent their own local centre. W. D. Robb, superintendent of motive power, is always present at these functions, and as he devotes considerable personal attention to the instruction and welfare of apprentices in the motive power department, and is much interested in their progress, what he has to say is usually along the lines of encouragement and stimulation to increased effort.

A Proud Record

The apprentices at Stratford have not only taken the first prizes for several years in the apprentices competition on the Grand Trunk System, but have also taken a number of prizes for several years for mechanical drawing at the Canadian National Exhibition, Toronto. The reputation of the apprentices at Stratford shops is so well known and the advantages accruing to those who enter employment there that apprentices have come from all over the continent even as far as China, two of these boys (sons of English parents) having come to Stratford to learn a mechanical trade. Apprentices include sons of doctors, lawyers, members of parliament and prominent railroad men.

Railway Men Responding Well

At the meeting referred to, it was pointed out that over 400 Grand Trunk employees, including 35 apprentices have joined the overseas service. The staff of employees at Stratford contributed a large portion of the bandsmen for different battalions, and a number of well trained first aid men, while a number of those who enlisted have since risen to positions of officers in the different battalions. Considering this the apprentices by resolution thought that they should forego their banquet this year, although it would be some sacrifice to do so, and decided to grant $50 to the Daughters of the Empire to assist in providing comforts for the soldiers who went and are going overseas. This is the second donation which the apprentices are giving, the first being for $100. When it is realized how much the boys appreciate their annual banquet and the great pains they took to make it a success, it makes the action taken all the more commendable.

As they have again won the first place on the System, Mr. Patterson promised them that they would have their annual excursion as usual. They have had this excursion for a number of years and enjoy the outing. Last year on account of the strenuous work in the munition department the apprentices there were not able to go.

ROBERT PATTERSON,
Master Mechanic, G.T.R. Shops, Stratford, Ont.

HIGH SPEED STEEL SCRAP

Arrangements have been made by the British Ministry of Munitions whereby the makers of high-speed steel will take back all scrap, short ends, etc., at uniform prices. The prices which have been fixed are:—10 cents per pound for turnings, and 12 cents per pound for bar ends, delivered at steelmakers' works. All material of this kind is to be returned as far as possible to the manufacturer who supplied the original steel. In cases where this is not possible, owing to supplies being obtained from a number of manufacturers, the scrap should be returned in proportion to the quantity of steel which was originally received. The scrap must be packed in convenient-sized barrels, or other suitable cases, and should be free from all foreign substance, and particularly other kinds of steel.

Turnings should be returned as soon as a reasonable quantity can be got together and not kept until rusted solid; such scrap is practically worthless. Under the regulations published in the 'London Gazette,' dated March 3, as 30 B of the Defence of the Realm, Regulations, it is illegal to dispose of high-speed steel through any but authorized channels, and users are therefore advised that the above arrangements should be carried out in every case.

INDUSTRIAL GAS

LECTURING recently before the Derby Society of Engineers on "Industrial Gas: Its Services to the Nation," H. M. Thornton described some of the many ways in which the gas industry is contributing to our efficiency in this time of war. The heat treatment of shells, he pointed out—a matter of vital interest to national existence—is largely carried out by gas furnaces, the even, reliable easily regulated heat of which is very valuable for such important processes. Some of these furnaces are comparatively small, but others are capable of annealing or heat-treating ten 15-in. armour-piercing shells at a time. Gas furnaces are indispensable for various processes in the production of 18-pdr. shrapnel shells and of 4.5-in. and 6-in. high-explosive shells, and are also used on a large scale for annealing the brass cartridge cases and the copper bands of shells.

Finally, in this connection there is the drying oven and trolley. Gas burners are placed around the bottom side of the oven, and trolleys of different shapes and dimensions are specially constructed to take the desired number of shells. The shells have to be dried in order to harden the varnish placed in the interior and thus prevent any chance of oxidation from the steel if the shell is kept in stock some time. This condition, however, said Mr. Thornton, is not one likely to be experienced, as we hope to "deliver the goods" with promptitude into the German lines.

A well-known Melbourne manufacturer received a contract for the Defence Department for a large quantity of entrenching tools, and in lieu of the ordinary imported steel he obtained steel produced at the Broken Hill Proprietary Company's works at Newcastle. He is now making what is most likely the first article of military equipment (except shell bodies) manufactured entirely from Australian raw material.

Power Driven Machine Tool Equipment on Board Ship*

By J. H. Thomson

While a regularly constituted workshop, more or less extensively equipped with machine and hand tools and appliances, is far from being a novelty aboard ship and more especially so in the case of the larger size war vessels, the fact remains that little progress has been made in the direction of providing merchant ships with at least a modest installation of power-operated apparatus that would successfully cope with a large percentage of the repair and overhaul work incidental to sea-going service. The subject matter of this paper makes evident that a power-driven machine tool equipment is worth while for many reasons.

It might be thought that in the present age of machinery, there would be little need to plead for up-to-date power-driven tools for executing the everyday mechanical work on board a modern steamship, yet the majority of ships will be found deficient in this respect, many possessing no power-tools whatever, others only a nondescript lathe put on board with considerable disregard of the probable requirements, size of ship, etc., and of the large range of work which can be economically carried out, if given suitable and suitably equipped tools.

Any repair that can be efficiently carried out on board ship, by the ordinary staff, without entailing the neglect of other duties and without entailing any overtime work, will cost considerably less than ashore. The enormous saving in time would in some cases avoid the ship being detained in port, and owing to the quickness and ease with which work can be done, the machinery will be kept in better repair, as the ship staff will have more time to devote to it.

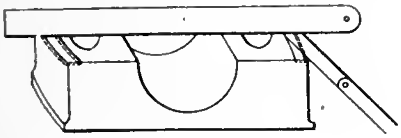

FIG. 1.

Stripping a Bearing

To take a simple illustration of everyday routine work:—Suppose a 3 in. diameter by 2 in. wide bearing wants stripping, the amount of metal to be removed—ascertained in the usual way by leads—is 25-1000. It could be put in the lathe, the amount required taken off to within 1-1000, a true plane surface left, parallel with the opposite plane surface of the bearing, or parallel with the bearing itself as may be required, sharp edges and rags removed—all in well under a half-hour, with a minimum of physical labour by anyone with a slight knowledge of turning.

In the vise, with a good file, the same job would take from an hour to an hour and a half and given a good tradesman, he might have the required amount off to within 3-1000 and in that time have an approximately plane surface, nearly parallel with the other surface of the bearing. With a poor tradesman however, there might be 5-1000 or more of error in the parallelism of the two surfaces. It should further be remembered

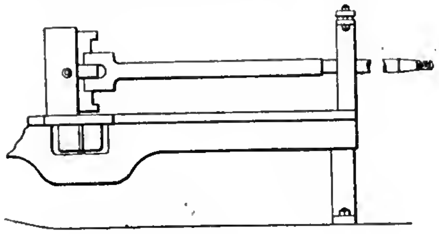

FIG. 2.

that such a job has often to be carried out in an engine-room at a high temperature. Doing the job in the lathe is more or less a pleasure to the engineer, and he is practically as fresh after its completion as he was before he started. Doing it in the vise is mere mechanical drudgery, and the engineer is wet with perspiration, and has lost a considerable amount of energy.

A simple method of taking off exactly the right amount of metal in the lathe might be given. Face up only about a quarter or less of the surface to be stripped, until, when laying a good straight edge across the old surface, the required feeler will just slip in between the straight-edge and the new surface, after which the remainder of old surface can be faced down to the same plane (see Fig. 1).

As illustrating a common repair, the valve-spindle of a steam stop-valve is

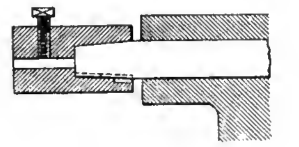

FIG. 3.

broken on the day of sailing. With a power-driven lathe on board, and a small stock of various sizes of brass rod, such a spindle could be replaced in about four hours, possibly less if it so happened that there were any old valve-spindles on board which could be worked up for the job. Without a lathe and with the necessity to send the spindle ashore to be made good, the time lost may be anything from a half-day upwards.

Equipment Minimum

The minimum power-driven tools advocated on board a ship are a lathe, a drilling-machine, and a high-speed grinder. These tools should be so arranged that each can be in use simultaneously. It will be most convenient if the three machines are grouped together, so that all may be driven off the one counter-shaft, fitted in the usual way with driving and loose pulleys. For driving the counter-shaft an electric motor complete with starting switch, etc., will be required, the power of the motor depending upon the size of the tools that it is proposed to instal; one of 2½ horse-power should be ample for all ordinary requirements. A point which might be considered is whether the motor might not be fitted so as to be capable of assisting the lathe gearing in getting the required

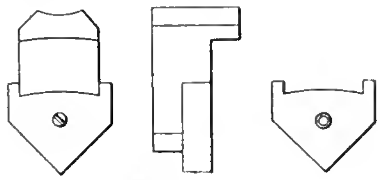

FIG. 4.

slowness of speed for turning a job of large diameter; such a job being of infrequent occurrence, there would be no objection to running the countershaft temporarily at a reduced speed. Getting the lathe to revolve slow enough is sometimes a bit of a problem on board; it can occasionally be solved however, by running the dynamo at a reduced voltage.

The Lathe

It is difficult to fix definitely the size of the lathe that should be fitted on board ship, and the point should be one that will bear discussion. The suggestion is put forward that the aim should be to have a lathe which, with the gap removed, would be capable of dealing with the high pressure junk-ring, the high pressure piston being the one which usually gives the most trouble from wear, etc. The length should be capable of

*From a paper read before the Institute of Marine Engineers recently.

dealing with any of the main-engine valve-spindles, not that it is thereby implied that the valve-spindle should be accommodated between the lathe centres. It will generally be sufficient if, by the aid of a fixed stay (Fig. 2), that part of the spindle which works through the neck bush, stuffing-box, gland and guide are capable of being efficiently dealt with.

Space in a ship for a lathe of such size is not always obtainable, but with a little contriving it should be managed, except in very small boats where the length may require consideration. A suitable position in a turbine-driven ship is often found in the shafting compartment which usually extends right across the engine space; there the lathe, drilling-machine, and grinder can be ranged along the ship's side, using the ship's frames for the purpose of attaching countershaft brackets, motor, etc. The forward starboard side is usually the more suitable, thus leaving the ends of the shears clear for any extra long job to overhang, this point should also be kept in mind if the lathe is placed in the engine-room, as one often sees the end of the shears close up against the ship's skin, which renders the turning of a long job impossible.

If the space is so limited that the end of the shears cannot be left clear, then they may abut on a hold or bunker bulkhead, which can have a circular hole cut in it in line with the lathe centres, such hole being made water-tight with a covering plate. This means that a time must be selected for doing any job which is extra long, when the bunker is clear of coal, or the hold of cargo. It may be mentioned that such a hole, by bolting a suitably shaped piece of wood to it, may be utilised as a fixed stay.

There is one point that must on no account be lost sight of in selecting a position for these tools. The space selected must be well ventilated, and cool enough at all times, even with steam on the main engines and the ship in the tropics, for a man to work in comparative comfort. The speed at which the ship's lathe can be driven requires more consideration than it usually gets; for seeing that there is only the one machine, it stands to reason that it should be capable of a very much larger range of speed than would be the case in shop practice. Thus, if the suggestion that the lathe should be capable of dealing with the junk-rink be accepted, then it follows that the lathe-spindle should be capable of being driven from a speed suitable for turning a small-diameter brass pin; and if the suggestion made later-on regarding the supplying of one or two emery wheels for use in the lathe be carried out, then the lathe-spindle should be capable of a higher speed still—say 1500 revolutions per minute—which is suitable for a 14-in. diameter wheel.

Cutting Screws

The ship lathe must be capable of cutting screws of all the standard pitches, and it may require to have one or two odd wheels for bastard pitches, if the engine-builder happens to be one of those who use bastard threads—a practice resorted to in order to compel the user to come back to the maker for renewals. The usual compound saddle-rest is required with cross-feed, etc. Quadrant should be marked off in degrees. The moving head-stock should have a cross-adjustment for purposes of alignment or turning up tapers.

A suggested fitting for the moving head-stock which would be of great use is a drill-chuck. This would be attached to the moving cylinder of the head-stock, the boring of holes in work which is attached to the running spindle being of much more frequent occurrence than of that in which the drill is attached to the running spindle. Drills are sometimes supplied capable of being placed in the taper hole which holds the fixed centre or a special drill-holder; but the practice is not good, as the hole gets damaged, and so renders the fixed centre shaky or out of alignment. A suggestion for a holder is given in Fig. 3, which is self-centring and free from shake, and can be detached by drawing in the cylinder by means of its screw, when the holder will abut on the barrel, and be forced off; a sunk feather is fitted to the holder, engaging in a keyway on the under side of the cylinder end.

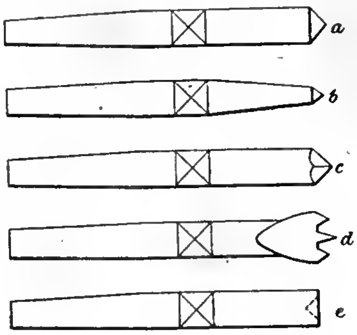

FIG. 5.

The attachments for the running spindle will consist of:—One large face-plate for use with gap removed; one face-plate for use with gap in place; one driver-plate for driving work held between the centres; and one chuck with four independent dogs, each having three steps, and capable of being reversed, and holding circular work securely when they are so. A shortcoming of most dogs is that they will not very readily catch small work, say, of 1/4 in. diameter.

In Fig. 4 is shown an attachment which will be found useful in this connection. Any one wishing to adopt it should make a wooden pattern a neat fit for the dog, and get four forged off it in tool steel; then true up one flat surface of the forgings and fit them to the dogs, making sure when boring the holes and fitting the pins that the strain when screwing up the job will not come on the set-pins. The set-pins will last better if they are also made of tool steel.

After the forgings have been fitted to the dogs, true up the sides of the V-shaped portion until the four points meet in the centre of the plate. The dogs lie in a true circle, and the sides of the V-shaped portions form true radii of a circle. The front faces of the segments may be faced up with the chuck running on the lathe spindle. The V-shaped portions should not come to absolute points, but be left about 1-16 in. wide; a small rack, consisting of a piece of 1/8-inch plate with four tapped holes to take the set-pins, is desirable to hold pins and segments when not in use.

There should also be supplied one drill-chuck which will hold the drills supplied to the ship; this may be one of the numerous small self-centring grip chucks, or a chuck with a plain parallel hole, say 5/8 in. in diameter, if the drills are, as is very common, forged from 5/8 in. round tool-steel bar; one fixed stay, which can be bolted down to the lathe shears; one running stay, which can be attached to the saddle—those with adjustable metal dogs are more useful than those requiring the fitting of various size wooden blocks; one hand-rest for wood-turning tools.

Fig. 5 shows the lathe centres required. These consist of two ordinary pointed centres; one ordinary pointed centre with end of reduced diameter for small work; one cutting centre; two or more driving centres for wood-turning, and one hollow centre (optional). A list of tools follows, those being of ordinary form, 1/2-in. or 5/8-in. square-section of common tool steel, this latter being selected, as the many special self-hardening steels require an experienced tool smith to deal with them. Tools made of such steel could be dressed ashore, but there is always the possibility of them getting broken when away from port and requiring to be redressed by the ship's staff.

The Acting British Consul at Helsingfors, H. M. Grove, reports that, with a view to saving expense and trouble, nearly all the Finnish paper mills have decided to become members of a society which has been formed mainly for the purpose of buying in co-operation raw materials for the various mills, such as sulphurous earth, china clay, chlorate of lime, calcium of soda, glauber salts, limestone, lime, resin, sulphur, lead, hoop-iron, iron wire and jute cloth.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

1 IN. X 7 IN. SCREW MACHINE

THE accompanying illustration shows a 1 in. x 7 in. screw machine equipped with automatic chuck and bar feed, having a capacity of 1 in. dia. bar stock through the chuck and a maximum distance from the end of spindle to turret of 15 in.

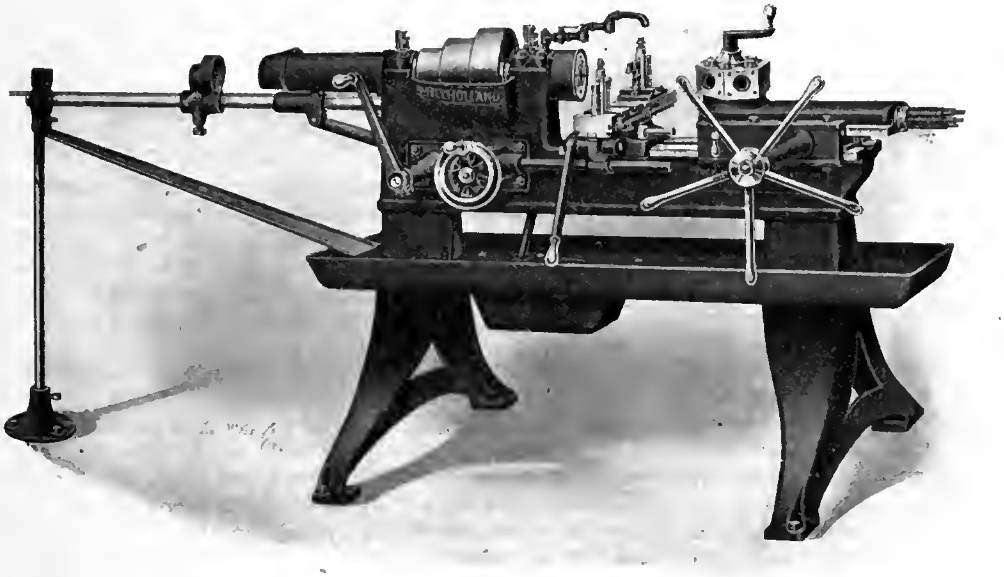
The headstock is cast solid with the bed, which is of ribbed box construction, the front and rear spindle bearings being tied together by side walls, which enclose the lower half of the cone pulley.

A high carbon steel forging forms the material for the spindle, which is finished by grinding, and is carried in die-cast bearings of large dimensions, provided with sight feed oilers. By a single movement of the lever in front of the headstock, the operator opens the chuck and feeds the bar while the machine is running. Slight variations in the diameter of the stock are automatically compensated for in the construction of the chuck.

The cut off slide is gibbed to a flat bearing on its carriage of ample size to insure rigidity under forming and turning cuts. By means of adjustable clips on a large diameter dial, it is possible to duplicate different shoulder lengths accurately with the hand longitudinal adjustment.

The turret, which may be either solid or hollow, is automatically indexed by the backward movement of the slide. The stud on which it revolves is tapered and is adjustable for wear; it is also bored so that long stock can pass through the turret and allow the use or short stiff tools. A pressed steel oil pan is fitted to the legs with complete lubricating system for cutting compound.

The W. K. Millholland Machine Co., Indianapolis, are the builders of this machine, some of the principal dimensions being: Swing over bed, 13½ in.; over-cut-off, 6 in.; cut-off feed, transverse, 5½ in.; longitudinal, 9 in.; holes in turret, 1¼ in. dia.; hole in spindle, 1 9-32 in. dia.; weight net, 1,275 lbs.; crated, 1,450 lbs.; boxed for export, 1,650 lbs.



1 IN. X 7 IN. SCREW MACHINE WITH AUTOMATIC CHUCK AND BAR FEED.

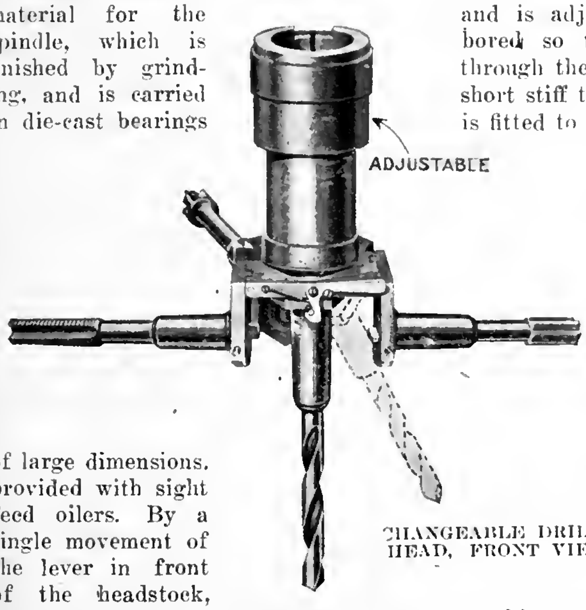
CHANGEABLE DRILL HEAD

THE accompanying illustrations show a changeable drill head, by means of which any one of four tools may be brought into use when required. The device consists of a sleeve which is clamped on to the lower end of the drill spindle sleeve, and which is provided with four swinging flanges, which support the tools as shown.

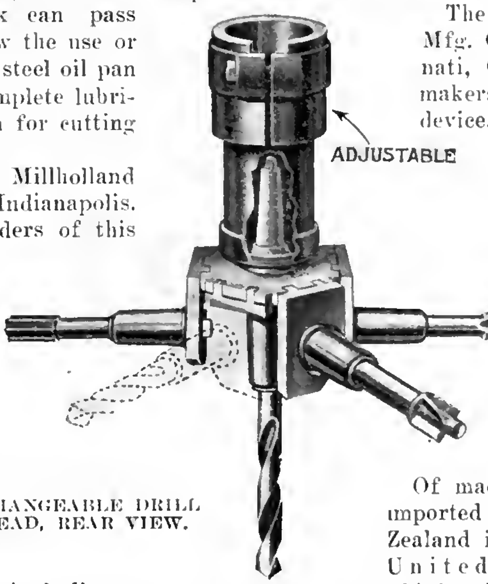
When one of these flanges is swung into position below the drill spindle, it engages with a socket driven by the drill spindle. When finished with, the tool is released by moving a catch shown on front view, when it swings out of engagement, allowing another one to be put into operation similarly. The drill head with the idle tools remains stationary, but is fed up and down by the sleeve on the drill spindle to which it is fastened.

When necessary, the sleeve in the head can be easily removed and bored out to suit any special machine; the standard hole supplied is 1½ in. dia., and two sizes of head are made with Nos. 2 and 4 taper shanks.

The Newman Mfg. Co., Cincinnati, O., are the makers of this device.



CHANGEABLE DRILL HEAD, FRONT VIEW.



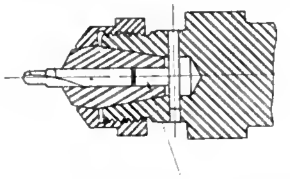
CHANGEABLE DRILL HEAD, REAR VIEW.

Of machine tools imported into New Zealand in 1914 the United Kingdom supplied nearly two-thirds; the remainder was shared by the United States and Germany.

FUSE RING ROUTING MACHINE

AMONG the many important operations necessary in the manufacture of fuses, that of routing grooves in the fuse rings is one of the most important, and calls for a high degree of accuracy. The universal horizontal routing machine illustrated was designed solely for routing fuse rings, and is built by the George Gorton Machine Co., Racine, Wis.

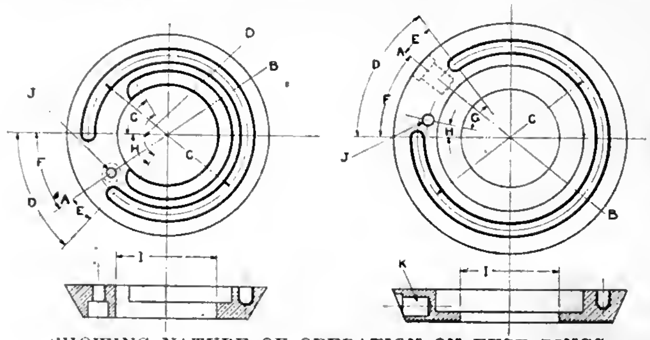
Among the most important features are the various adjustments which can be had, as illustrated by the requirements of the fuse rings shown in line drawing. Dimension C may be anything up to 4 in., angle D may be from 0 to 360 degrees, gauge holes may be in any position on top, bottom or side of ring, and distances E, F, G, and H are adjustable. Varying diameters of centre hole I necessitate the use of different plates



DETAIL OF ROUTING TOOL AND CHUCK.

made of hardened and ground steel, on which the ring is clamped by means of a drop forged fork and hardened cam.

The cutter spindle runs approximately at 3,200 revs. per min., and is carried in ball bearings mounted inside a sliding sleeve, which is clamped by means of a heavy yoke to another similar sleeve. The spindle pulley and the loose pulley are arranged together in the space between the sleeves, the whole being carried in two large bearings forming part of the frame. A simple type of spindle



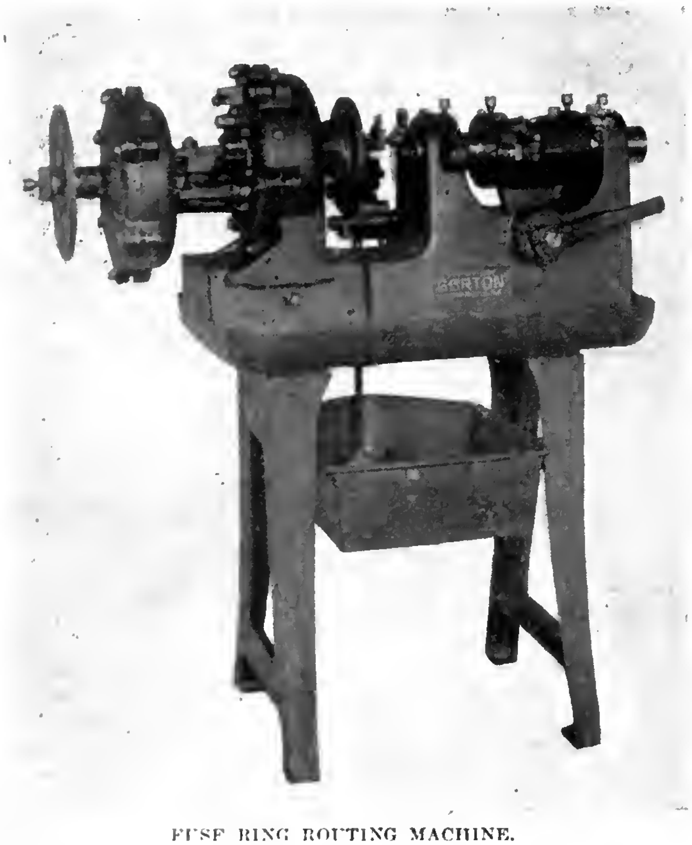
SHOWING NATURE OF OPERATION ON FUSE RINGS.

collet is used, which permits easy changing of cutters, uniformity in length of cutters being an important point.

In order to obtain good work the cutter should not project more than the minimum of 3/8 in., under which condition the groove is finished smoothly and accurately with one cut, and a production of 25 to 30 rings per hour can be maintained.

Stops are all made of hardened tool steel, and operate inside of the work holder case. The feed pulley is mounted on rear case and operates the work holder by means of two pairs of reduction spur gears. The work holder bearing is of a patented type, which runs in oil, is quickly adjustable and eliminates all vibration in the work. A complete cutter lubricating system is furnished except when machines are used on a bench and operating details are simplified, so that one operator can run three machines.

The complete machine weighs 810 lbs. net, and 900 lbs. crated.



FUSE RING ROUTING MACHINE.

STEEL CO. OF CANADA OUTLOOK

THE annual meeting of the Steel Company of Canada, held at Hamilton on April 25, was featured by important addresses by C. S. Wilcox, the new chairman of the Board, and Robt. Hobson, the new president. Mr. Hobson took a decidedly optimistic view regarding the outlook, even after the cessation of the present large contracts for munitions. Mr. Hobson, in dealing with the conditions that would likely prevail after the close of the war, pointed out that he did not want to assume the position of being a prophet, but there were conditions that warranted an optimistic view being taken. For a number of months after the war readjustments would have to take place, but once those were effected, good business should prevail for the steel companies. In this connection he pointed out that the railway companies were again coming into the market and were realizing that there would likely be a shortage of steel in 1917.

Mr. Hobson announced it had been decided to instal three new open hearth furnaces, which would increase the production 400 tons per day. "We have shipped nearly four million forgings for shells and blanks for high explosive shells, and would say that we are away ahead on delivery of everything asked of us by the Imperial Munitions Board."

C. S. Wilcox, the new chairman of the board, referred particularly to the finances of the company. He said in part: "As to the future, we must remember that conditions are not normal, and while business is satisfactory now, the directors and officers have serious problems to consider for the future. The cost of manufacturing has materially increased, prices for war munitions have been reduced and the Government has imposed a tax on our war profits, the amount of which cannot now be determined. This year we will have a steel production much larger than we have ever sold before, and it may be advisable for us to put in additional finishing plants at some points to take care of this extra tonnage."

Adjustable Bench Heights.—Production may be facilitated by having a bench the height of which may be adjusted. In the cleaning room the output of the grinders is increased many per cent. by providing them with stands which can be raised or lowered at will. The lowest level enables the castings to be tipped on and off easily, while the higher levels bring pieces up to a point best suited to the height for working of the individual grinder. Width should be considered from the human angle. Extremely wide benches may furnish large capacity, but they entail laborious reaching; moreover, invite the use of the rear part for the storage of odds and ends.

GENERAL BUSINESS, SHIPPING AND SHIPBUILDING

INDUSTRIAL conditions continue to show steady improvement, the immediate and future outlook being, generally speaking, such as to engender and foster optimism. Canadian business enterprise is perhaps on a more stable basis than at any time in its history, and is marked by a caution that augurs well for its permanent maintenance in that respect. While the possibilities of developing an export trade have been fully realized for many months now, we have only recently taken active measures to get into touch with it, a circumstance, however, that is in no sense indicative of tardiness, but rather expressive of the already-mentioned caution and desire to fit and adapt ourselves to one or more of the trade opportunities that the war has made available.

In this connection it may be stated that not a few of our steel mills and allied enterprises are already taxed to the limit of their capacity on export business, the latter embracing practically every country in the world with the exception, of course, of enemy countries. The effect in these instances has been to create a commodity scarcity as regards domestic requirements, and have the natural consequence of causing increased prices in the latter sphere. However, if the export campaign as it develops intensity, works out as successfully as anticipated, it will not only lead to the maintenance of a favorable trade balance after the war is over, but will offset any tendency to a reactionary period which might be expected to set in immediately peace is declared.

The steel market, which after all is the real barometer and foundation of the industrial activity of this or any country, continues to maintain strength, the demand for steel being as insistent as ever. Our own mills as well as those of the United States have all the business they can handle for this and a large slice of next year, and, in saying that much, we are far from straining the situation. A shortage of labor is the meantime bugbear, and the immediate outlook is that manifestation of the latter may become more aggressive. The upward price tendency of practically all manner of commodities continues, and indications are that we are yet some distance from the peak.

Shipping

So far as our leading steamship lines are concerned, the season's arrangements are well advanced, freight services as well as some passenger services being already inaugurated. Prospects are of the brightest description for an active and remunerative business in both spheres, and no effort is being spared in equipping to meet it. Perhaps the most interesting development of the past month has been the acquisition by the Canada Steamship Lines of the fleet of the St. Lawrence & Chicago Steam Navigation Co.

Wood and Steel Shipbuilding

The revival of wood shipbuilding on our Atlantic seaboard warrants passing notice, and, taken in conjunction with the activities of and demand for this class of vessel, it may not be amiss to infer that our Maritime Provinces of New Brunswick and Nova Scotia will achieve again at least a fair measure of the glory of accomplishment that the building of "wind jammers" brought them ere steel shipbuilding took pride of place. The shortage of "bottoms" of every construction and size is, of course, primarily responsible for the rejuvenation of the wood shipbuilding industry, although doubtless the high prices obtainable for such type craft is giving added impetus to the industry.

The propagation and development of steel shipbuilding and marine engineering is not, however, being allowed to lie dormant as a reference to the address delivered before the Canadian Manufacturers' Association in Montreal, by Col. Cantley, president of the Nova Scotia Steel & Coal Co., New Glasgow, N.S., amply proves. An abridged report of same appeared in our issue of April 27. Both the need for an up-to-date Canadian merchant marine and for its being in large part, if not wholly a Canadian product, are given ample vindication, and the parallel drawn and the results achieved through Government recognition and support of railroad and steel manufacturing enterprises is distinctly illuminating, well-timed and forceful as an argument.

The reference by Col. Cantley to Government support of our steel industries in years past is one that is easy of appreciation in times like the present, bringing vividly to our mind's eye the practically certain conditions that would have prevailed in Canada during these months of war—absence of munition and war supplies orders, had steel-making lacked the national recognition that has enabled it to place our Dominion on a production plane of world competitive degree. It is but natural to expect that what has been accomplished through Government support of railroad transportation and steel-making, will be equally procurable in the realm of shipbuilding.

Concerted action is, of course, necessary so that the proposition as outlined by Col. Cantley assume definite shape and become effective, and perhaps no better opportunity could have been secured than that provided by a meeting of the Canadian Manufacturers' Association, sectional although it happened to be. A large percentage of those present on the occasion of Col. Cantley's address had a more or less vital interest in what he had to tell them, and the fact that his keenness of perception in business matters generally and his dogged perseverance in pursuing an ideal to its logical end, may be taken as an earnest that the movement to support shipbuilding in Canada will not only continue to gather weight, but will begin to show results before long.

The dearth of freight carriers—lake and ocean, is of immediate importance to this Dominion, just as much so, as to any other nationality, and we look to see the authorities at Ottawa deal with the situation in such a way as to mitigate to the fullest extent possible the inconvenience thereby caused by stimulating shipbuilding on a generous scale on our lake and ocean borders.

Prices Per Lb. Unless Otherwise Stated.

requirements of the trade are as pressing as ever, and the mills are hard put to it to meet deliveries. In many cases recent advances have been made with the object of discouraging further buying. The volume of business at the mills is so large that producers have been unable to catch up with deliveries, and stock supplies are constantly being reduced. In many instances factories have been greatly handicapped owing to the non-delivery of raw material. The supply of plates is gradually improving, but little relief is evident, as the mills are booked far in advance and the demand continues. An advance of $5 per ton has been placed on plates, and these are now quoted at $4 for ¼ to ½; heads at $4.25, and 3-16 inch tank plates at $4.30 per hundred. Prices on cold rolled shafting have again advanced $5 a ton; many producers are booked for the remainder of the year, premiums being offered for small early shipments. Dealers here are now asking 50 per cent. plus list prices. The difficulty in securing sheet bars and the heavy demand for finished product, especially for blue annealed, electrical and deep stamping sheets is keeping prices on the upward path. Black sheets, 28-gauge, are now $4.10; 10-gauge, $4.60; Canada plates, dull, $4.25; Colborne crown, No. 28, $7. These prices show an increase of approximately ¼c over last week. With many of the large consumers practically covered for from six months to a year, the demand for boiler tubes is apparently as great as ever, and prices are ever upward. An average of 10 per cent. has been added to the prices on lapwelded tubes from 2 inches up; 2-inch being now $12.75; 2¼ now $15.45; 2½ now $17.20; 3-inch now $19.50; 3½ now $24, and 4-inch now $30.60 per hundred feet.

Machine Tools and Supplies

The heavy demand for machinery in large quantities has been falling off for some time, but tool builders are kept busy filling contracts, not only for munition plants, but also the continual demand for domestic equipment. Inquiries are very good for small orders, which involve one or two tools. Some inconvenience is anticipated during the next few weeks, owing to labor troubles and settlements, but it is generally expected that satisfactory agreements will be arrived at, which will prevent any serious results at the present time. The unceasing demand for all kinds of supplies continues, and prices in many cases are still advancing.

Old Materials

Trade in scrap materials is quiet, and, while dealers are well supplied, the demand from consumers is light. Many of the mills are well stocked, and there is little indication of early buying. Prices generally are declining in the States, but

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., May 1, 1916.—The industrial situation is becoming seriously affected by the apparent shortage of labor, and many plants are experiencing great difficulty in securing and retaining sufficient help to keep them operating. In addition to the scarcity of men, the possibility of labor troubles are evident in many circles, which makes it hard to define the present and immediate future conditions. The opening of navigation has materially aided in the transportation of materials, but insufficient tonnage of vessels is resulting in the reopening of shipyards which have long been closed. There is also a possibility of establishing new plants for the construction of steel vessels on a large scale. Orders for additional munitions are still being placed, and shell making plants are still working at capacity, but in some instances are inconvenienced by lack of raw material and shortage of help. Many plants have, during the past few months, made large additions to their factories.

Pig Iron

The pig iron situation remains unchanged. Many of the large furnaces have been obliged to refuse additional orders, as their books are filled to the close of this year, and in some cases well into 1917. Prices, however, are holding firm.

Steel

While the demand for steel and steel products has apparently fallen off, the

prices here are firm. Wrought iron pipe has advanced 1c, and is now quoted at 11½c. Heavy lead is ½c weaker at 7c per pound. Scrap zinc shows a similar decline, being quoted at 15c per pound.

Metals

The general tone of the metal market is one of dullness, with prices weakening. The heavy buying noted in copper a few weeks ago has been followed by a spell of quietness, and the market at present is inactive. Tin is also quiet, and some difficulty is being experienced in obtaining permission to ship metal. Spelter is very quiet, and the supply is becoming greater than the demand. Lead is lower and demand falling off. Antimony is plentiful and prices are declining.

Copper.—Following the heavy demand of the past month, the market has become comparatively quiet, and inquiries for spot and future metal are light. Owng to the heavy sales,recently made to foreign buyers, it is almost impossible to secure first or second quarter delivery. New York quotations for August delivery for electrolytic are nominal at 28½ cents. London reports a strong market, £140 being quoted for electrolytic. The general situation is one of firmness, and prices remain strong and unchanged. Local dealers are asking 33c for lake, 32½c for electro, and 31c for castings.

Tin.—The feature of the week's market is the prevailing uncertainty of obtaining shipping licenses in London. Some inconvenience is expected in securing tin to meet the requirements of existing contracts. However, most consumers are well covered for early needs, and the general tone of the market is quiet and inclined to weaken. New York quotes 49¾c, being 1¼c lower than the previous week. Dealers here report fair demand, and prices are firm at 50c per pound.

Spelter.—The dullness in the spelter situation is having the effect of weakening the market, and prices are declining. Considerable metal is being offered for re-sale in many quarters, and further weakness is looked for. The present condition is largely due to recent reports of the U. S. Geological Survey, which show large prospective increases in production. A decline of 1c is noted in New York prices, but local conditions are unchanged and prices are firm at 23c.

Lead.—The present lead situation is quieting down, and the market is showing signs of dullness. The export demand is falling off and domestic needs are lighter. Consumers are well supplied for immediate needs, and are not anxious to buy, although sellers are anxiously looking for bids. Both the Trust and outside prices are lower, and the nominal quotation in New York is 7½c. Local conditions are unchanged, with prices firm at 10c.

Antimony.—Plentiful supplies of antimony are resulting in a quiet market, and prices are declining. Dealers here report a decline of 2c; this week's price being 45c per pound.

Aluminum. — Unchanged conditions prevail and prices are firm at 68c.

Toronto, Ont., May 2. — Customs revenues continue to make an exceptionally good showing and the returns for April are a fair indication of what may be looked for during the year. The revenue for April was $10,346,000, being $4,070,000 more than the corresponding month of last year. The increase is largely accounted for by importations of materials being used in the manufacture of goods destined for shipment abroad. Although the export trade is steadily increasing it is being seriously handicapped by the shortage of ocean tonnage. The situation in this regard is acute and there appears to be little prospect of any improvement this year.

The congestion of freight on the railways has been relieved to some extent, but the embargo on shipments to Eastern points is causing considerable inconvenience to manufacturers. The scarcity of labor in conjunction with a shortage of raw materials will result in a scarcity of many finished iron and steel products. Prices continue to advance and there is no indication that the top has been reached. The more important lines affected this week include wrought iron pipe, cut nails, wrenches, some makes of taps and dies, etc., some sizes of boiler tubes and cotton waste.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel Market

The extraordinary activity in the steel trade is unabated and the mills continue operating at full capacity. Plants are being extended to take care of the increasing demand but a shortage of labour is a problem which is becoming more and more serious. The output of steel is increasing in tonnage but at the same time deliveries are getting more backward. Prices of steel products continue to advance due to the shortage of raw materials and general activity in the trade. A further advance in wrought iron pipe has been made following higher prices in the States. The advance is two points on black, and three points on galvanized pipe. The demand for pipe is heavy and the market very firm. Some sizes of lapwelded boiler tubes, 2-in. to 3-in. have advanced about 10 per cent. Here again the market is very firm and a further advance is looked for. Nearly all makers of locomotive and merchant tubes are sold up for practically the remainder of the year.

Prices of cold rolled shafting have advanced in the States but are unchanged locally in the meantime, although higher prices are expected. Cut nails have advanced 20c and are now at $3.40 per 100 lbs., per keg base. Higher prices for wire nails are expected in the trade but they are unchanged this week. A new price on rivets has been announced. Boiler rivets ¾ in. and larger are now quoted at $4.60 and structural rivets same sizes, $4.50 per 100 lbs. New discounts on nuts have been issued. Finished and semi-finished nuts up to 1 in. are now 50 per cent., and finished and semi-finished nuts over 1 in., 37½ per cent. The new discount on iron rivets, 7-16 in. and smaller, is 37¼ per cent. Higher prices on bolts are looked for in the near future.

The market for sheets continues strong and quotations very firm with an upward tendency. The new demand for blue annealed sheets is still heavy, some mills being sold up for the entire year. The production of steel sheets is nearly up to rolling capacity but there is still some trouble in getting sheet bars. The situation in the galvanized sheet trade is unsettled owing to the high price of black sheets and spelter. Some galvanizers are not operating their plants while others have considerably reduced their production.

The steel market in the United States is steadier and few price movements are noted during the week. The situation is unchanged, the demand on the mills for deliveries being as insistent as ever. Steel bars are unchanged at 3c, plates 3.75c, and shapes 2.60c, f.o.b. Pittsburgh. Forging billets have advanced and are now being quoted at $68.50 per ton, Pittsburgh. Wire rods are still being quoted at $60 per ton Pittsburgh for shipment at mill convenience.

Old Metals

The market for old materials is generally easier and business dull. Prices of copper and brass scrap are firm but the market is quiet. Heavy melting steel is stronger and has advanced, being now quoted at $10. Stove plate and No. 1 cast iron are also higher, being quoted at $10.50 and $14.50 per ton.

Machine Tools

The market is quieter and the demands for machine tools lighter than for some weeks. Those concerns who are changing over their plants to make larger calibre shells are buying some equipment and there is also a fair demand for standard tools particularly for tool rooms.

Supplies

The general tendency of prices continues upward and a number of lines have advanced recently. The new discount on "Trimo" and "Stillson" wrenches is 60 per cent off list, and parts 57½ per cent. The Butterfield Co., have issued a new discount list which covers general advances of about 5 per cent. Some of the more important new discounts are: pipe stocks and dies: Nos., 0, 3, and 4, 60 per cent.; Nos. 1, 1½, and 2, 70 per cent.; dies, Nos. 0 and 3, 50 per cent.: Nos. 1 to 2, 60 per cent.; Reece taps, blacksmiths, 40 per cent.; machinists hand, ¼ to 1, 50 per cent.; machine screw, 60 per cent. and 55 per cent.: Reece screw plate, 50 per cent. Pipe taps 1¼ to 2, 70 per cent.

Prices of white and colored cotton wiping waste have been advanced ¾c per lb., owing to the high cost and scarcity of raw materials. Prices on wool packing waste and washed cotton wipers are still withdrawn and are only on application. The linseed oil market is weaker and prices have declined 1c per gallon. Oil is now quoted at 96c for raw and 99c for boiled. Turpentine has declined 2c and is now quoted at 75c per Imperial gallon. Gasoline and benzine are unchanged but an advance is expected in the near future.

Metal Markets

The feature of the market is the continued strength of copper which is a shade higher than last week. The demand is still heavy but considerably less than it has been recently. Tin is unchanged but is firm and the market has an upward tendency. Spelter is also firmer and buyers are showing more interest in the market. Lead is dull and the outside market is weaker being now at the same level as the "Trust" figure. Antimony is weaker on all positions and quotations have declined slightly. The aluminum market is featureless and unchanged. Solders are quoted at the same level as last week.

Copper.—The market is very strong and a continued good demand is reported. The producers are in full control of the market and they are now sold so far ahead that they are not in a position to supply any large buying demand except for delivery during the fourth quarter. Copper has advanced ½c locally and is now quoted at 32c per pound, nominal.

Tin.—The market is firmer with an upward tendency. The tin situation is stronger and there is a good demand for this metal. Local quotations are unchanged and nominal at 56c per pound.

Spelter. — The New York market is steady and firm but London advanced £2 per spot and £1 on futures. The French Government is buying big tonnages of spelter in the United States market. Local are unchanged at 22c per pound.

Lead.—The market is dull and weaker. The "Trust" is holding lead at 7.50c New York, but the outside market has declined and is now at the same level as the "Trust" figures. Lead has declined ½c locally and is now quoted at 10c per pound.

Antimony.—The market is weaker in all positions and no improvement is noted in the demand. Antimony has declined 1c locally and quotations are nominal at 47c per pound.

Aluminum.—The market is featureless and unchanged at 68c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

REVIVAL IN WOOD SHIPBUILDING

SO great is the demand for Canadian tonnage that it has been found necessary to revert to the building of wooden vessels of the sailing type, a condition somewhat unique in the shipping world. When steel-built vessels supplanted the wooden craft, few of which have been constructed in recent years, it was never thought that the old-style craft would ever be revived. War has, however, changed conditions, and incidentally brought about a condition of affairs on the upper lakes that was never dreamt of before the war started.

A. B. MacKay, of Hamilton, a well-known vessel owner in Canadian marine circles, states that he has placed an order with a shipbuilder at Meteghan, Digby County, Nova Scotia, for the construction of a four-masted wooden vessel, to cost $75,000. The same firm has just laid keels for ten vessels of a similar type for other Canadian owners. These vessels will be used in the North and South America coastwise trade and in the West Indies service, and under the terms of the contracts they are to be delivered for service in October next. Their gross tonnage will be 1,200 tons.

The scarcity of Canadian tonnage occasioned by the transferring of some forty-five freighters from the upper lakes to salt water service has created a keen and spirited revival in the shipping world for vessels of all types, many of which have changed ownership since the outbreak of the war. While many of the leading vessel owners have been prepared to place orders for the building of new vessels, it has been found almost impossible owing to the increased price of steel, the delivery of which would not be guaranteed within a limited time.

The consequence has been that the wooden vessel has found a ready market by reason of the fact that the timber is available, and the builders are in a position to guarantee deliveries in time to meet the demands of the vessel interests, hence the preference for the sailing craft under existing conditions. Mr. MacKay states that the schooners will be completed in every detail, and will be fully equipped with all the modern appliances necessary for the loading and unloading of cargoes.

WIND JAMMERS STILL A FACTOR

THE war's effect on the shipping industry was made evident recently in Montreal, when it became known that the sailing schooner "N. W. White," 90 tons net register, wintering in the harbour, and recently purchased by the Eastern Canada Fisheries, Ltd., had been chartered to carry a cargo of lumber to the British Isles at the record figure of 360s. a standard. When it is considered that before the war the rate was 33s. 6d. a standard for vessels of similar tonnage, it will be readily seen what a tremendous increase in freight rates the present scarcity of tonnage is causing.

The company recently purchased from Captain Bernier, of Quebec, the schooner "Minnie Maud." This vessel, which has been owned by Captain Bernier for several years and used by him on some of his Arctic expeditions is of 200 tons capacity, and of the regular sailing ship type which, about fifty years ago frequented the Port of Quebec, and were at that time big factors in the shipping industry of the city. These primitive vessels, the "Minnie Maud" was built in 1891, and the "N. W. White," as long ago as 1878, are now undergoing general repairs when they will be placed in charge of experienced mariners, and placed on the high seas.

A few years ago these wooden craft

were at the suggestion of the underwriters, removed from ocean service, as they were regarded as a menace to the shipping trade, as well as being dangerous to the more modern and faster steamers, who occasionally ran them down in heavy fogs, causing loss of life, and cargo, resulting in the insurance rates on this class of transport being doubled. Mariners were therefore obliged to abandon the high seas, and seek the fishing trade as a source of livelihood. Now, after a period of some twenty years, it would seem we are obliged to resort to the primitive and slow craft of a generation ago.

ZINC AND SPELTER IMPORTS

PRIOR to the war about 50 per cent. of the blocks, pigs and bars, etc., of zinc came from Belgium, 20 per cent. from Germany, 15 per cent. from Great Britain and 15 per cent. from the United States. About 75 per cent. of the spelter came from the United States before the war, and now the United States is supplying practically all the blocks, pigs, bars, etc., and also the spelter. Very little is coming from Great Britain. The U.S. had been getting zinc ore from Canada in the vicinity of Trail, B.C.

Canadian imports of zinc and spelter for the year ending March, 1914, were:

Blocks, pigs, bars, etc., 45,700 cwt., with a value of $271,100.

Zinc spelter, 117,000 cwt., with a value of $600,000.

For the year ending March, 1915, the imports were:

Blocks, pigs, bars, etc., 30,240 cwt., with a value of $200,000.

Zinc spelter 130,000 cwt., with a value of $712,000.

For 11 months ending February, 1916, the imports were:

Blocks, pigs, bars, etc., 11,260 cwt., with a value of $198,000.

Zinc spelter, 130,250 cwt., with a value of $1,889,000.

CUSTOMS REVENUE INCREASE

A sixty-five per cent. increase in Canadian Customs revenue is shown by the figures for the month of April just ended, as compared with those for the same month of last year. The revenue for the past month was $10,346,000, which is $4,070,000 more than the corresponding month of 1915, when it was $6,276,000.

April is the first month of the present fiscal year, and its showing may be taken as an augury of the trend of Customs revenue. It is noteworthy in this connection that the Customs revenue of April, 1915, exhibited a decrease of $200,000 as compared with the same month in 1914, so that in starting off the present fiscal year with a four-million-dollar advance, Canadian revenues are making an exceptionally good showing.

Vancouver, B.C.—The Begg Motor Co. will build an addition to their plant.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Halifax, N.S.—The Halifax Graving Dock Co., will erect a machine shop on their property here.

Quebec, Que.—Price Brothers & Co., are considering extensions to their lumber mill, to cost about $200,000.

Toronto, Ont.—The Brandon Co., propose building a machine shop at West Toronto to cost approximately $5,000.

Ingersoll, Ont. — The new purifiers have arrived at the gas plant and preparations are being made for their installation.

Toronto, Ont.—The Toronto Harbor Commissioners are to erect a brick machine shop on the Don division near Mill street at a cost of $13,500.

Truro, N.S.—The town council contemplate buying, and renovating the Chalmers Electric Co.'s plant. New power plant equipment will be installed.

Listowel, Ont.—Hydro Electric Radiation, Ltd., are considering the erection of a factory. Manager, G. E. Harrison, 704 Traders Bank Building, Toronto.

Hamilton, Ont.—A building permit has been issued to the Dominion Sheet Metal Co., for the erection of a factory extension on Burlington street, to cost $6,000.

Kirkland Lake, Ont.—H. Oakes, Lake Shore Mine, is in the market for a 200 h.p. motor, air compressor, drills and pumps.

Medicine Hat, Alta.—The Saskatchewan Bridge & Iron Works is contemplating the completion of its plant this year.

Berlin, Ont.—The Onward Mfg., Co., will build a factory here, 45 x 100 ft., three stories, for the manufacture of electric vacuum cleaners, etc., T. A. Witzel is manager.

Toronto, Ont.—The Toronto Type Foundry Co., is in the market for one 10-in. or 12 x 42-in. universal grinding machine, one 3 or 4-ft. radial drilling machine, and one tool and cutter grinding machine.

Medicine Hat, Alta.—The Dominion Harvester Co., whose plant was recently destroyed by fire are making arrangements to start operations in another building. The company are in the market for machine tools and other equipment.

St. Catharines, Ont.—The contract for the Canadian Aloxite factory has been awarded to Brown-Pollard Co., of Niagara Falls, N.Y. The plant will be erected at Montrose, and the building will cost $100,000. There will be three railway sidings to the property.

New Toronto, Ont.—The Brown Copper & Brass Rolling Mills are building an extension to the plant for the manufacture of munitions. This is going to be a fireproof structure of brick and steel. The work on this extension, which has been going on for some time, will be finished almost immediately.

St. John, N.B.—The first step in building Messrs. T. McAvity & Sons' large iron foundry on the site between the Marsh Road and Westmorland Road was taken recently, when the firm made application to the city council to confirm the agreement made in April, 1914, by Act of the Legislature, defining the terms of purchase, release of the old Water Street premises, etc.

Electrical

Petrolia, Ont.—The installation of the new street lighting has practically been completed and the formal opening will take place shortly. The system has cost about $35,000.

General Industrial

Berlin, Ont.—The Onward Mfg. Co. are building an addition to their factory.

Brantford, Ont.—It is reported that an American concern contemplates establishing a woollen mill here.

Hamilton, Ont.—The Graselli Chemical Co., will build an addition to their factory here to cost about $30,000.

Medicine Hat, Alta.—The Lake of the Woods Milling Co.'s plant was totally destroyed by a mysterious fire on April 28. The loss is estimated at $500,000.

Guelph, Ont.—The White Sewing Machine Co., of Canada, have taken over the business of the Raymond Mfg. Co., of this city. The company have purchased a 20-acre site in St. Patrick's ward where a new factory will be erected. W. W. Chase, secretary of the White Co., of Cleveland, Ohio, is manager of the new concern, which is capitalized at $500,000.

Winnipeg, Man.—The mills of the Rice Malting Co. of Canada, in St. Boniface, were destroyed by fire on April 30. The whole plant is a total loss, amounting to over $300,000, with insurance of $200,000. R. Rice is president and general manager of the company.

Municipal

Victoria, B.C.—An extension to the high pressure water system is contemplated.

Levis, Que.—Extensions to the water distribution system are contemplated by the town council.

Ridgetown, Ont.—A by-law will be submitted to the ratepayers to sanction improvements to the waterworks system.

North Bay, Ont.—The city council propose extending the water main system. Cast iron pipe will be required.

Winnipeg, Man.—The city council have decided to purchase a gasoline engine driven pumping outfit for the Fire Department at a cost of about $9,000.

Rodney, Ont.—A by-law to authorize the installation of a lighting and power distribution system will be submitted to the ratepayers. Estimated cost, $7,000.

Dundas, Ont.—The town council propose building a sewage disposal plant at an estimated cost of $38,500. Aird Murray & Lowes, of Toronto, are engineers.

Port Carling, Ont.—The Town Council propose spending $1,000 on electric lamps. A by-law will be submitted on May 15.

Elmira, Ont.—The ratepayers will vote on a by-law shortly to sanction a loan of $6,000 to the Ideal Shoe Co., who propose building a factory here.

Matheson, Ont.—A by-law will be submitted to the ratepayers to raise $25,000 for waterworks and sewage disposal systems.

Smith's Falls, Ont.—A by-law was carried here recently authorizing an expenditure of $1,600 on improvements to the waterworks system.

Welland, Ont.—The Dominion Incinerator Co. will construct an incinerator plant here. W. M. German, M.P., of this town, is interested in the company.

Gore Bay, Ont.—A by-law will be submitted to the ratepayers on May 8 to authorize a $500 bonus and tax exemption to W. E. George, who proposes to erect a planing mill here.

Arthur, Ont.—A by-law will be submitted to the ratepayers on May 8 to raise $15,000 for the purchase of John Philip's electric lighting plant and to provide for the cost of a distribution system.

Galt, Ont.—The ratepayers on April 28 turned down an opportunity to add to the fire fighting appliances of the city, defeating a by-law for the purchase of a motor fire engine by a vote of 277 to 380, and a by-law for a fire alarm system by a vote of 244 to 422. The Fire Underwriters' Association find conditions in Galt very unsatisfactory.

Personal

Leonard Foulds and A. B. Bowes have opened an office at 166 Bay street, Toronto, as structural and civil engineers.

Wm. Steele & Sons Co., Philadelphia, Pa., architects and engineers, have opened an office at Room No. 423, Ryrie Bldg., Toronto.

Richard Reid, agent-general for Ontario, and **John Howard**, agent-general for Nova Scotia, are in Paris attending the Inter-Parliamentary Commercial Congress, which opened on April 27.

F. G. Smith, salesman with the A. C. Leslie Co., of Montreal, has left for Winnipeg, where he has received a commission as Lieutenant in the 183rd Overseas Battalion.

Trade Gossip

The Hudson Bay Zinc Co., of Salmo, B.C., has been incorporated with a capital of $5,000,000.

The Grand Lake Coal Co., of Fredericton, N.B., has been incorporated with a capital of $49,000.

The Pioneer Elevator Motor Repair Co., of Winnipeg, has been incorporated with a capital of $5,000.

The Canadian Ice Machine Co., Toronto, have been awarded a contract for an ice plant for the hospital at Hamilton, Ont., at $3,645.

The Otis-Fensom Elevator Co., Hamilton, Ont., have been awarded the contract for an electric elevator for the new hospital at Hamilton, Ont.

Port Arthur, Ont.—It is reported that the blast furnace capacity of the Atikokan Iron Co., will be considerably increased and that operations will begin shortly. J. Dix Fraser is manager of the company, which has recently been reorganized.

William Kennedy & Sons., Owen Sound, Ont., are making a specialty of casting and cutting off steel ingots ready to forge into shells of any size, but particularly those 6 inches in diameter. About 2,500 tons of steel ingots monthly, including shell steel, can be supplied by this concern for the next six months.

The Turbine Equipment Co., Toronto, have recently secured a contract from the Imperial Oil Co., of Sarnia, Ont., for four single-stage De Laval centrifugal pumps, which will be direct-connected to 75 h.p. motors. The capacity of each unit is 3,750 gallons a minute, against 95 ft. total head. The company have also received an order from the Standard Chemical Co., of Toronto, for one 1¾ million-gallon De Laval centrifugal pump, to operate against 125 ft. total head.

Clyde Shipyard Workers.—According to the Liverpool Courier, many Clyde shipyard workers are at present earning over $2,500 a year, and are not paying one cent into the National Exchequer. Shipyard workers can easily make $50 weekly, and even work less than the usual stipulated fifty-four hours. Some squads of riveters—three men and a boy—have earned $163 weekly since the war broke out, the hours worked being only forty-eight. Our contemporary gives the source of its information as a prominent Clyde shipbuilder.

Electric Furnace Development.—A recent article in the trade press called attention to the fact that all the electric furnaces in Germany, operating under war conditions, were turning out 129,646 metric tons of steel every twelve months. We are advised that if the Snyder electric steel furnaces recently sold, and those in operation to-day were suddenly mobilized for war service, on a twenty-four hour basis, they would turn out 77,975 tons of steel every twelve months, or within 40 per cent. as much steel as all the electric furnaces operating in Germany. These figures do not, of course take into consideration twelve furnaces sold in foreign countries, as well as several furnaces sold on this continent which cannot be used for the melting of steel. Europe is the mother of the electric furnace, and the steel foundrymen in Europe are considered very progressive. Judging, however, from the above facts, we also are keenly alive to the value of the electric furnace.

Tenders

Burlington, Ont.—Tenders will be received up to May 13, 1916, for a two-ton combination chemical engine hose truck. Specifications on application. Jas. S. Allen, clerk.

Hamilton, Ont.—Tenders will be received up to May 8, 1916, for supplying mechanical rakes and appurtenances for Gage avenue pumping station. Plans and specifications may be obtained upon application to A. F. Macallum, city engineer.

Toronto, Ont.—Tenders will be received by the Chairman Board of Control, City Hall, up to May 9, 1916, for the supply of two gasoline-driven diaphragm pumps. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall.

Regina, Sask.—Tenders for glass insulators, toppings, connecting sleeves, cross arms, galvanized iron wire, pole line hardware, steel strand wire, anchor rods will be received until May 6. Specifications, form of tender and all information may be obtained on application to the Department D. C. McNab, deputy minister, Department of Telephones, Regina.

Ottawa, Ont.—Tenders for submarine cable will be received at this office until May 15, 1916, for 10 knots of single conductor submarine telegraph cable (107 lbs. copper and 150 lbs. gutta percha per knot), with sheathing of 12 No. 8 S.W. G. iron wires, to be delivered at Halifax, N.S. Specification and forms of tender can be obtained on application to the office of the general superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa.

Toronto, Ont. — Tenders will be received up to May 6, 1916, for the undermentioned trades required in the erection of a factory building for The T. Eaton Co., at Toronto, Ont., iron work, rolled steel sash, steel partitions and doors, sheet metal work, roofing, waterproofing, rolling steel doors. Plans and specifications may be seen and form of tender obtained by applying at the office of Wm. Steele & Sons Co., 423 Ryrie Building, Toronto.

Contracts Awarded

Dartmouth, N.S.—The Rhodes Curry & Co., Halifax, have been awarded the general contract for the addition to the Williston Steel Foundry Co. plant.

Halifax, N.S.—The city council have awarded contracts to Drummond, McCall & Co., for cast iron pipe, and to Dartmouth Foundry Co., for castings.

Toronto, Ont.—The Board of Control has awarded a contract for thirteen car bodies for the civic street cars to the Preston Car Co., of Preston, Ont. The price was $4,907 each.

The Matagami Pulp & Paper Co. have awarded a contract for a power house to be erected at Smooth Rock Falls, Ont. W. Morrow & Beatty Co., Peterborough, Ont., contractors.

New Incorporations

The Comfort Mining and Leasing Co., has been incorporated at Toronto, with a capital of $40,000 to acquire and develop mineral and deposits. Head office at Cobalt, Ont. Incorporators, Geo. Ross, Thos. G. Code and F. A. Todd all of Toronto.

Corrugated Paper Box Co., has been incorporated at Toronto, Ont. with a capital of $200,000 to manufacture corrugated paper and paper boxes of every kind. Head office at Toronto. Incorporators, James H. Spence and Grant Cooper of Toronto.

The Canadian Aloxite Co. Ltd., has been incorporated at Ottawa, Ont. with a capital of $100,000 to manufacture, abrasives, chemicals, spirits, explosives and other products. Head office, Stamford, Ont. Incorporators, Reginald H. Parmenter, Arthur J. Thomson and W. Symon Morlock all of Toronto.

The Kaustine Co., has been incorporated at Toronto, Ont., with a capital of $40,000 to carry on business as sanitary engineers and general manufacturers and contractor. Head office to be at Toronto. Incorporators, Harry A. Newman and Williams E. Sommerville of Toronto.

The Byrns Pneumatic Ship Raising Co., Ltd., has been incorporated at Toronto, with a capital of $40,000 to acquire by purchase patents of invention granted for apparatus for raising submerged ships. Head office, Hamilton, Ont. Incorporators, Harry Byrns and William F. Condon of Hamilton.

The Flint Varnish & Color Works of Canada, Ltd., has been incorporated at Ottawa, Ont., with a capital of $250,000 to manufacture oils, paints, varnishes enamels, colors, etc. Head office at Toronto. Incorporators W. W. Wallace and J. J. Carton both of Flint, Mich., and George William McLaughlin of Oshawa, Ont.

The Burlington Metals Co. Ltd., has been incorporated at Toronto, Ont. with a capital of $40,000 to manufacture articles consisting of copper, brass, bronze, iron and steel or other metals. Head office, Hamilton, Ont. Incorporators, Reginald H. Parmenter, Arthur J. Thomson and William Symon Morlock all of Toronto.

The Reliance Foundry, Ltd., has been incorporated at Ottawa, Ont., with a capital of $50,000 to carry on business as general founders, and manufacturers of soil pipes and fittings of all kinds. Head office, Montreal, Que. Incorporators, Emilien Daoust, Antonio Valiquette and Joseph A. St. Yves all of Montreal.

The Hamilton Tar & Ammonia Co., has been incorporated at Ottawa, Ont., with a capital of $50,000 to manufacture chemicals, drugs, oils, ammonia and all chemical by-products of coal, etc., head office to be at Hamilton. Ont. Incorporators, Robert C. Fearman, D. C. R. Martin and A. T. Proctor all of Hamilton.

The White Sewing Machine Co., of Canada, Ltd., has been incorporated at Ottawa, Ont., with a capital of $500,000 to take over the Raymond manufacturing Co. of Guelph, Ltd., also "The White Sewing Machine Co., of Canada at Hamilton, Ont." Head office at Guelph, Ont. Incorporators, Chas. L. Dunbar, Leo W. Goetz and John Sutherland all of Guelph.

Marine

Kingston, Ont.—The Canada Steamship Lines propose building a wharf at the foot of Wolfe Island.

Port Arthur, Ont.—Work has commenced on two steel freighters at the Western Drydock & Shipbuilding Co.'s plant.

London, Ont. — The supplementary estimates include $100,000 for improvements to the London and Port Stanley harbor.

Toronto, Ont.—The Toronto Harbor Commission have received fifteen tenders for the harbor head wall to be constructed in the Bay extending from Brock street to Bathurst street. The cost is estimated at $250,000.

C. N. R. Fleet Sold.—It is reported from London, England, that the Cunard Company has completed arrangements for the acquisition of the Canadian Northern's shipping business. The negotiations have been pending for some time.

Quebec, Que.—Good progress is being made with the graving dock at St. Joseph de Levis. The entrance piers have been completed and the excavation of the ground for the dock itself will soon be commenced. The area to be cleared covers 138,000 sq. ft. and the excavation will be carried to a depth of 60 ft. The dock when completed will be 1150 ft. long by 120 ft. wide at base and 144 ft. wide at the top.

Victoria, B.C.—The American steamship Mariposa, of the Alaska Steamship Company, has arrived at Seattle from Esquimalt, where she has been undergoing extensive repairs at the plant of Yarrows, Ltd. The Mariposa was wrecked last October. Yarrows, Ltd., were awarded the contract covering the reconstruction of the interior cabins and damaged superstructure. The work was completed in several days under the contract time.

Trade Gossip

Galt, Ont. — A local syndicate has taken over S. T. Shimer & Sons' business. The new company will continue to manufacture the "Shimer" cutter heads.

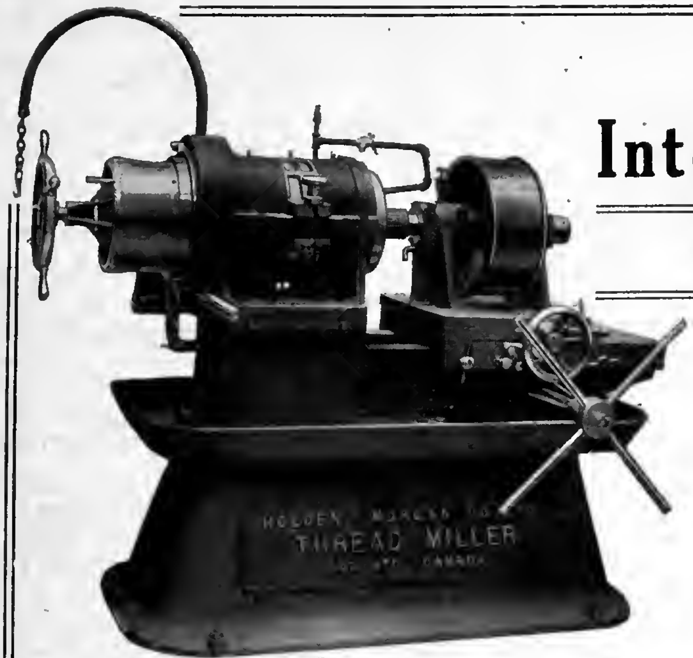
Investigating Steel Industries. — Thomas W. Gibson, Deputy Minister of Mines for Ontario and member of the Nickel Commission, and Dr. Willett G. Millar, provincial geologist for Ontario, have left for Paris to consult the French Government and to investigate the steel industries of France. They have visited the principal refining plants in Britain, including the Mond works at Swansea.

J. D. Lachapelle & Co., 317 St James Street, Montreal, recently sold to the Intercolonial Ry. at Moncton, N.B. a complete electric arc welding equipment of 600 amperes with automatic control panels, also one to the Montreal Cotton Co. of Valleyfield, Que., of 400 amperes with automatic control panels, to be used for general repair work."

The Consolidated Mining & Smelting Co., of Canada, Ltd., has shipped its first car of electrolytic zinc from the nine units of the $1,000,000 plant at Trail, B.C. The other eight units may be in service in the next fortnight. In a short time the daily production will be increased to 50 tons and a gradual further enlargement will ensue up to maximum of 100 tons daily.

G. T. R. Directors.—At the annual meeting of the G.T.R. directors held in London recently, Sir Arthur Yorke, C. B., late chief inspecting officer of railways, Board of Trade, and Stanley Baldwin, M.P., were elected to fill the vacancies, caused by the death of Lord Welby and the resignation of George von Chauvin. The Board of Directors is therefore now as follows: A. W. Smithers, chairman; Sir Henry Mather Jackson, E. J. Chamberlin, president of the company; S. Baldwin, M.P.; J. Brace, W. M. Macpherson, Sir Felix Shuster, Sir H. A. Yorke, and Sir W. Lawrence Young.

Toronto Customs Revenue.—Customs revenue at the port of Toronto continues to increase. The amount for the month of April was $2,767,307, a new high record in the history of the city. As compared with the figures for April last year they show a gain of $1,264,510. The figures for the last six months show a gain of $6,810,912, in compari-



The Holden-Morgan

Internal Thread Millers

Representing 7 in., 8 in. and 9 in. sizes.

The machine illustrated above has for its principle simplicity and perfection, and was designed especially for milling the internal threads on the nose or base of the shell body.

The shell is carried between two conical surfaces in the interior of the mandrel, this ensures the thread being milled perfectly true with the axis of the shell, and holds the shell in a much firmer and truer position than is possible with collet chucks. The master screw is chased on the outside of the mandrel, which entirely precludes the possibility of "drunken threads."

The milling head is carried in movable carriage and both slides are moved up to positive stops and locked so that thread is milled absolutely the same size in every instance.

Each machine is complete with oil-pump and pan.

NOTE—Countershaft is provided with machines over 6 in. size only, as smaller sizes are run direct from line shaft.

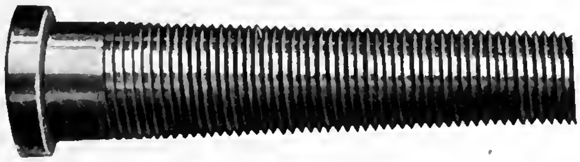
Taper Threading With a Geometric Die Head is a Simple Matter

The chasers follow the taper of the work automatically, and release the work at the end of the cut. Head is withdrawn without touching the finished threads.

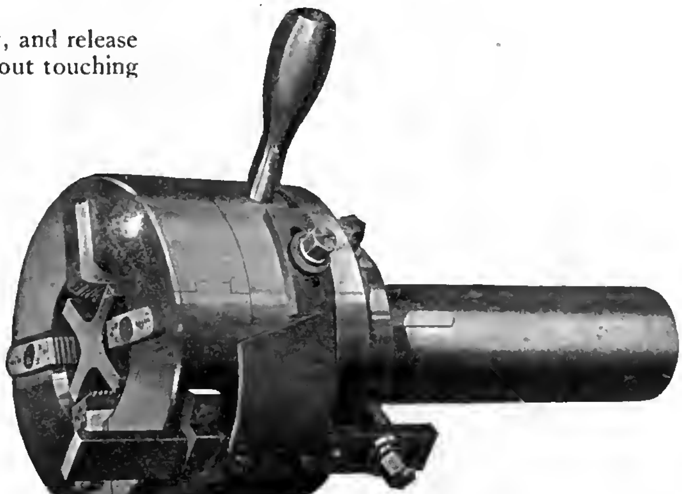
Geometric Taper Threading Die Heads are adapted to Screw Machines and Turret Lathes. When not cutting taper threads, the Head can be removed, leaving the machine free for other work.



Made to order, specially suited to requirements of machine and work.

Employed very generally at present on fuse work.

—Consult us about your taper threads—



A Geometric Taper Threading Die Head.

son with figures for the corresponding period a year ago.

Amherst, N.S.—The Ledcote Co., of Canada, Ltd., has taken over a property here and is installing plant for covering sheets, etc., with lead as a substitute for galvanizing. William Knight is president of the concern.

U.S. Copper Supply.—Copper production in the United States, for the calendar year 1915, is given by the Geological Survey at 1,388,009,527 pounds, against 1,150,137,192 pounds in 1914. Refined copper for 1915 is stated at 1,634,000,000 pounds, an increase of 100,000,000 pounds over 1914. Stocks of refined copper on hand: January 1st, 1915, 173,640,501 pounds; January 1st, 1916, 82,210,835 pounds. Copper consumed in 1915 was 1,043,461,982 pounds, against 620,445,373 pounds in 1914.

U.S. War Exports.—Total of war exports in 18 months to February 29, last was approximately $2,000,000,000. Exports of brass during March were about $24,000,000, or nearly four times greater than the total shipments during the calendar year 1914. Arms and ammunition exported during 18 months are valued at more than $250,000,000, including $16,000,000 in firearms, $33,000,000 in cartridges, $2,600,000 dynamite, $84,400,000 gun powder. Exports of 289 aeroplanes were valued at $2,550,000.

Building Notes

Toronto, Ont.—The T. Eaton Co. will erect a large warehouse, three storeys and garage on Teraulay Street, at a cost of $100,000.

Toronto, Ont.—A building permit has been issued by the city architect to E. W. Gillett Co., to erect a grain elevator and mill at Pardee avenue and Liberty street, at a cost of about $13,000.

Toronto, Ont.—The City Architect has approved of the plans for a two-storey brick addition to the Separate school at the north-west corner of Renhold and St. Clair Avenues. The additions are estimated to cost $19,500.

Toronto, Ont.—The City Architect has issued a permit to the Gutta Percha Rubber Co., to erect a reclaiming building at the north end of West Lodge avenue. It is a two-storey brick and steel building, and is estimated to cost $30,000.

Toronto, Ont.—The city architect issued a permit to the Toronto Hydro-Electric System to erect an addition to the transformer station on the south side of Cherry street near Front street. The building is to be of brick, and will consist of three storeys. It is estimated to cost $6,000.

Railways—Bridges

Montreal, Que.—The Montreal and Southern Counties Railway has been intended as far as Granby, Que. This section comprises 54 miles of track and 4 sub-stations.

Halifax, N.S.—A bill is now before the Provincial Legislature to confer power on the Lockeport Transportation Co., to build a railway from Lockeport, to Lockeport Junction, a distance of four miles.

Catalogues

Blowing Engines made by the Nesta Machine Co., Pittsburgh, Pa., are dealt with in a catalogue recently issued. Some large installations are illustrated accompanied by a brief description.

The Vanadium-Alloys Steel Co., Pittsburgh, Pa., have now ready for distribution to the trade, a new folder which describes their Red Cut Superior High Speed Steel. In addition, this pamphlet offers suggestions concerning heat treatment. A copy will be mailed free upon request.

Air Heater and Air Blower.—Bulletin No. 219, issued by the B. F. Sturtevant Co., Boston, Mass., deals with the "Sturtevant" electric air heater and blower. The apparatus is fully described and the various purposes for which it can be used are given in detail. A list of sizes with capacities is included and the illustrations show a few different types indicating their varied application.

Homestead Valves.—A bulletin illustrating and describing various styles of valve made by the Homestead Valve Mfg. Co., Homestead, Pa., has been received. The essential points of these valves are dealt with fully and particularly with regard to the quarter-turn feature of their construction.

Steam Traps.—The George W. Cole Co., Toronto, Ont., have issued a new booklet illustrating and describing their line of boiler feed, return feed, lifting and vacuum traps. The illustrations include a diagram of a double trap installation. Other items include a price list, particulars of the "Cole" oil separator and a list of users of the "Cole" trap. Copies of this booklet may be had on application.

Detroit Stokers is the title of an attractive catalogue being distributed by the Detroit Stoker Co., Detroit, Mich., to feature the "Detroit" automatic mechanical stoker. Excellent illustrations show in detail the construction of this stoker and its principal features; its methods of operation are also described fully. Other illustrations of a similar quality show a large number of typical installations at various power plants. The "Detroit" stoker engine is illustrated and described and some useful efficiency tables, etc., are included.

Steam Saving Devices.—An interesting line of steam saving and protective devices are dealt with in catalogue No. 18 which is being distributed by the Strong, Carlisle & Hammond Co., Cleveland, Ohio. The specialties include steam and vacuum traps, separators, pump governors and pressure regulators, stop valves and engine stops, etc. Each appliance is described fully with special reference to its principal features. Sectional views are given showing the general construction and the method of operations is also described diagrams show some of the specialties installed and price lists with dimensions for the various sizes are included.

Nordberg Oil Engine.—Bulletin No. 27A deals with the high compression oil engine made by the Nordberg Mfg. Co., Milwaukee, Wis. The bulletin describes fully the "Nordberg" oil engine which is of two-cycle type and built in three sizes up to 200 h.p. This engine is claimed to be the simplest oil engine on the market and the principal features embodied in its construction and upon which this claim is based, are described fully. The bulletin contains a number of excellent half tones showing different views of the engine, detail sectional drawings and scavenging cards. Copies of the bulletin may be obtained on application.

INDEX TO ADVERTISERS

The Forging and Machining of 60 Pounder Howitzer Shells

Staff Article

Where circumstances have permitted the combination of forging and machining operations under one management, it has been productive of satisfactory results, not only to the management of the particular plant involved but to other factories depending on such a plant for their supply of forgings. Difficulties in machining, due to defective forging or peculiarities in steel composition are more promptly and efficiently remedied when the forging plant is in close contact with the machine shop as in the plant described in this article.

THE work involved in the complete manufacture of a shell from iron ore to the stage where it is ready for receiving the explosive charge, includes operations of widely different natures, requiring plant and equipment of such variety that only in a few cases has it been possible for firms in the country to do such work in its entirety. Quite a number of concerns, however, have undertaken the work of forging in conjunction with machine work with beneficial results to the shell output of the industry as a whole.

In the case of the plant, the layout of which is shown in Fig. 1, arrangements were made for producing forgings for 4.5 in., 60 pdr. and 6 in. shells, and also for machining a portion of the output of the two smaller sizes. The 60 pdr. constituted much the greater proportion of the work machined and the plant is an interesting example of continuous operation from forging to finishing under one management and one roof, the shipping of the finished shells being done within a stone's throw of the point where they are forged.

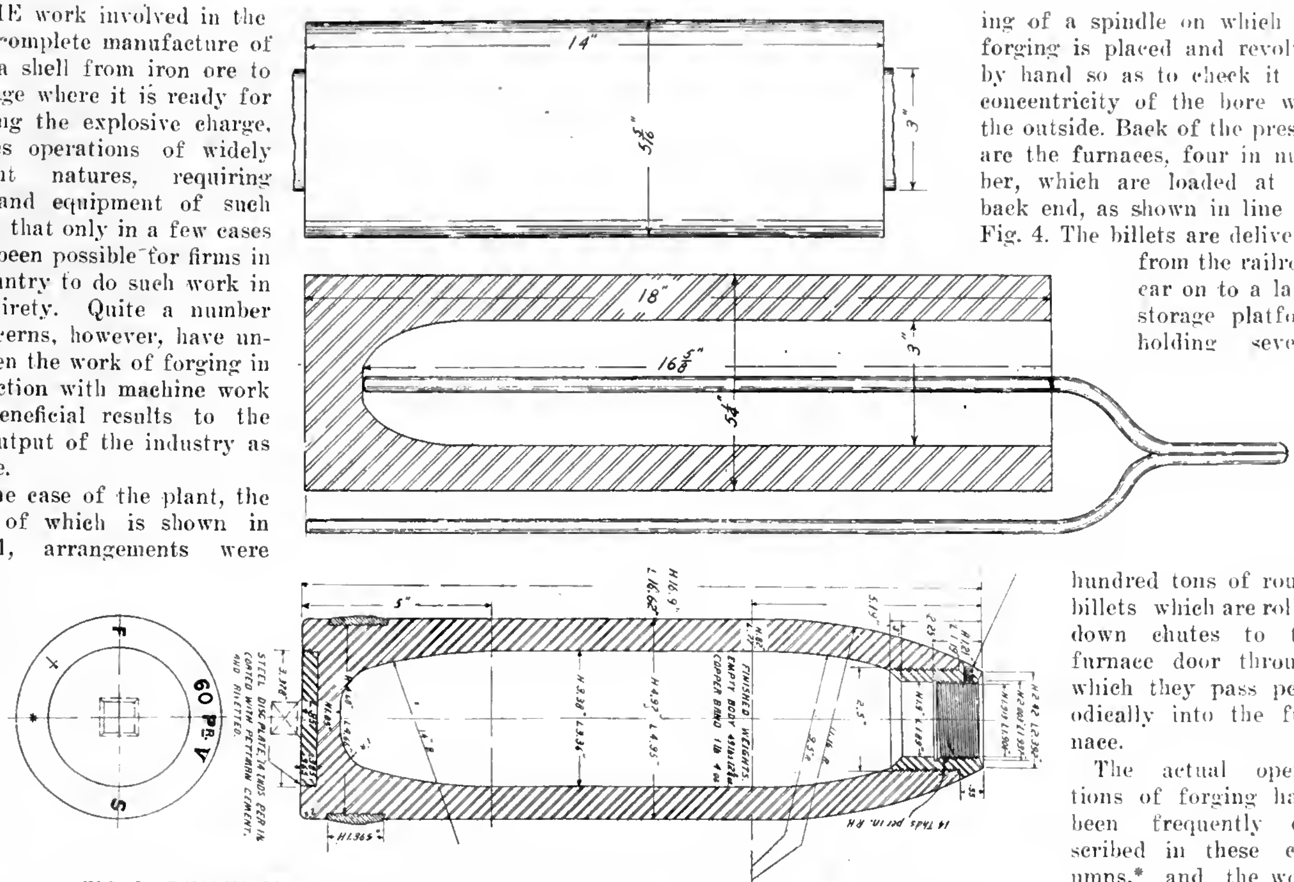

FIG. 2.—DIMENSIONS OF 60 PDR. SHELL IN VARIOUS STAGES OF COMPLETION.

In Fig. 2 are shown three sketches, the upper one giving the dimensions of the rough billet as received from the steel mills, the centre one showing the rough forging as delivered to the machines, and the lower one the finished shell as shipped from the machine shop to the loading plant. The forging operations on the billet are simple compared with the numerous machining operations, but the simplicity is more than offset by the powerful presses and heating furnaces necessary for the handling of the work.

A general view of the forging department is given in Fig. 3, which shows the forgings cooling off in front of the presses while to the left of the picture are a couple of testing fixtures consisting of a spindle on which the forging is placed and revolved by hand so as to check it for concentricity of the bore with the outside. Back of the presses are the furnaces, four in number, which are loaded at the back end, as shown in line cut Fig. 4. The billets are delivered from the railroad car on to a large storage platform holding several hundred tons of rough billets which are rolled down chutes to the furnace door through which they pass periodically into the furnace.

The actual operations of forging have been frequently described in these columns,* and the work as done here is in very close accordance with the best practice at present existing. Referring to Fig. 1, the left hand press is constant-

*See Canadian Machinery, Jan. 27, Manufacture of Shell Forgings.

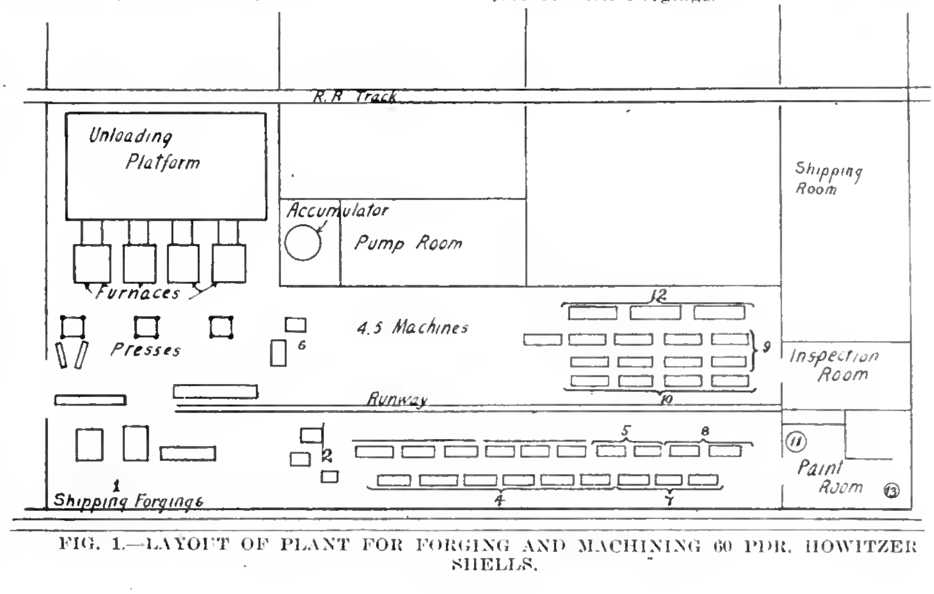

FIG. 1.—LAYOUT OF PLANT FOR FORGING AND MACHINING 60 PDR. HOWITZER SHELLS.

ly engaged on 4.5 shells, performing the work in one stroke. No drawing properly speaking is done on the shell, as the

FIG. 3.—GENERAL VIEW OF SHELL FORGING DEPARTMENT.

billet is placed in the die, and the piercing punch forced down into it with the consequent upward extension of the metal out of the die. The return stroke of the press withdraws the punch after which the hot forgings are removed from the die by means of suspended tongs, see Fig. 5, and deposited in gravity conveyors which carry them to the cooling bed. The press illustrated is equipped with two punches and dies so as to make use of the full power of the press.

60 Pdr. Forgings

The work of producing 60 pdr. forgings is divided between the other two presses which are equipped with single punches. The centre press is used for piercing only, which operation is practically identical with that just described. The pierced billet is now ejected by means of knock-out gear which forces up the bottom of the die, and is immediately placed in the end furnace at the right where it is again brought up to forging heat to be followed by drawing down to size in the third press. This is done by bringing down the press so that the point of the punch exerts a certain pressure on the bottom or pocket of the shell which is supported on a die plate held over the opening of the main die. After this pocket is formed, which is done in a few seconds, the punch is drawn up a short distance to allow the die plate to be withdrawn, when the punch is forced downwards through the main die, the tapering bore of which reduces the outside of the forging to the required size.

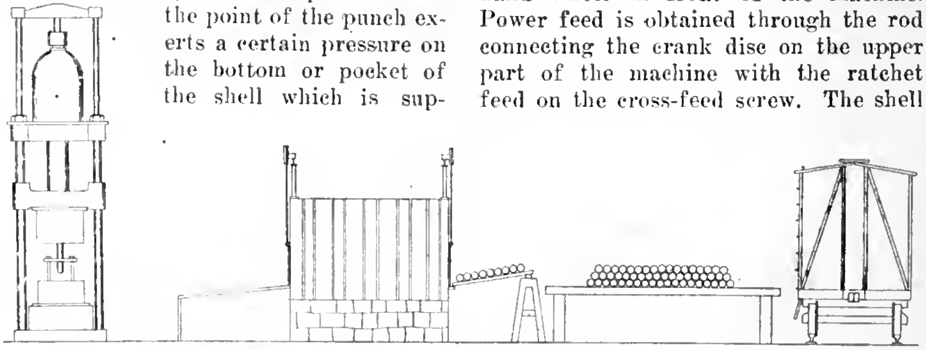

FIG. 4.—ILLUSTRATING CONTINUOUS PROGRESS OF WORK FROM FREIGHT CAR TO FORGING PRESS.

The hot forgings are piled up in batches as shown so that cooling takes place very slowly minimizing the possibility of hardening. When cool enough to handle, the forgings are checked up for overall length and depth by means of a simple gauge as shown in Fig. 2 centre. After being checked for concentricity on the fixtures previously referred to, the forgings are taken to the cutting-off department where the bases are faced off to thickness and the open end trimmed to length.

Cutting Off

The machine illustrated in Fig. 6, is a Kennedy double-end, four tool machine which operates on both ends of the forging simultaneously, the two tools at each end being located opposite each other and fed into the work by the large hand wheel in front of the machine. Power feed is obtained through the rod connecting the crank disc on the upper part of the machine with the ratchet feed on the cross-feed screw. The shell itself is held in a double ended hollow chuck encircled by a spur driving ring the whole being mounted in suitable framing. The handwheel to the left of the machine is geared to a rod which is moved to a certain position every time a new forging is placed in the chuck, and locates the job from the inside of the base, being withdrawn when cutting off commences.

In addition there are two Hall machines of standard type, one facing bases and the other trimming mouths.

This particular plant was fortunate in securing uniform equipment in the matter of machine tools, with the accompanying benefits resulting from the interchangeability of small tools, and the certainty with which operators could change over on machines when required, without reduction of output due to strangeness in handling different machines.

Boring

Machining the bore is done after cutting-off, six 30 in. American lathes being in use. These are fitted with plain and substantial turrets which carry four tools arranged as shown in Fig. 7. These are used in rotation as numbered, i.e..

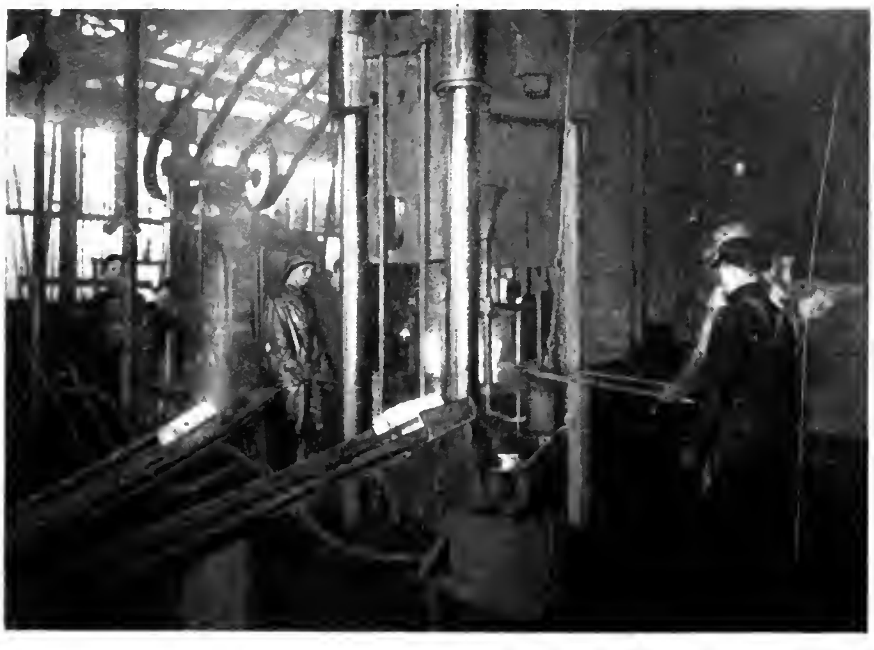

FIG 5. FORGING 4.5 IN. SHELL BLANKS IN A PRESS EQUIPPED WITH DOUBLE PUNCHES. HOT BLANKS TRAVELING ON GRAVITY CONVEYOR.

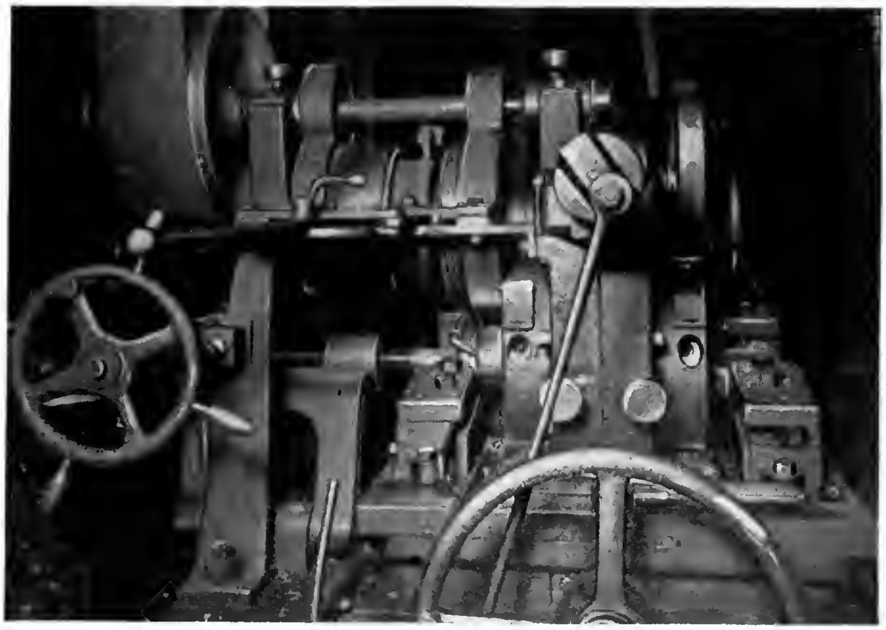

FIG. 6. FOUR-TOOL CUTTING-OFF MACHINE OPERATING ON BOTH ENDS OF SHELL SIMULTANEOUSLY.

rough bore, rough bottom, ream bore and bottom, and bevel mouth. The finished bore of the shell is now used to locate the work on an expanding arbor.

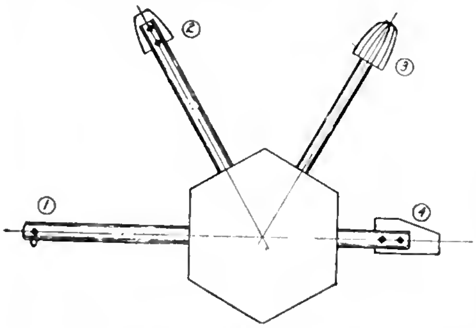

FIG. 7.—ARRANGEMENT OF BORING TOOLS IN LATHE TURRET FOR MACHINING 60 PDR. SHELLS.

when the base or outer end is turned down to size to receive support from a cup centre carried in the tailstock spindle. The support derived from this now enables the outside of the forging to be rapidly reduced to rough finished dimensions, a slight increase in diameter at the mouth being obtained through the use of a forming bar controlling the slide rest. This work is also performed by six 30 in. American lathes, one of which is illustrated in Fig. 8.

Two 30 in. Bertram lathes take care of the grooving and waving, after which a slight nosing-in or bottling of the open end is performed in the conventional manner with a hydraulic press, followed by machining the nose which consists of boring, tapping, facing the end, and blending the interior curve of the nose into the parallel wall of the shell. This latter work is done on three 30 in. American lathes with turret carriages similar to those already mentioned.

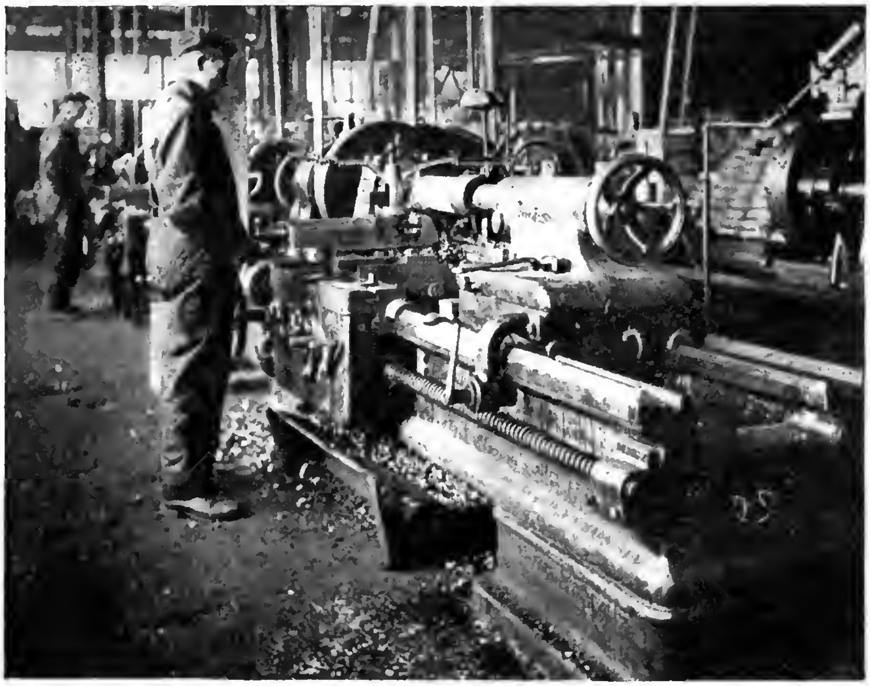

FIG. 8. 30 IN. ENGINE LATHE ROUGH TURNING OUTSIDE OF SHELL.

Recessing

Two other similar machines are engaged continuously in recessing the base, the tools used for this work being simple in design and efficient in practice. The recessing tool is shown in Fig. 9, being ground to shape from a round bar, and fed straight into the base as shown in the sketch at the right. The manner of forming the cutting edge enables the tool to be moved to or from the centre to adjust the diameter and carry the cut fully across the centre of the recess. Final sizing is done by a fluted reamer of regular type. No threading is done in the recess as the base plugs or gas checks are riveted in with pneumatic caulking hammers which tighten up the joint in a satisfactory manner.

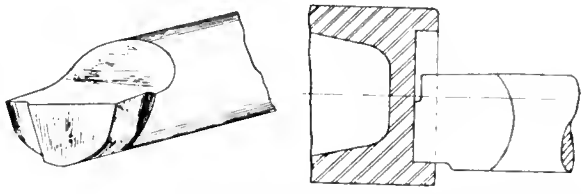

FIG. 9.—SIMPLE TYPE OF TOOL USEDIN RECESSING BASE FOR PLUG.

The excess metal of the base plug is now faced off to size, after which the shell is finish turned to size and profile. Nine C.M.C. 18 in. lathes are devoted to this work, the shell being driven by the base in a simple collet type of chuck and the nose supported by the tailstock centre in a service plug. A profile bar arranged in conventional manner, controls the tool slide so as to impart the desired shape to the nose of the shell.

After being thoroughly cleaned and examined, the shell is weighed and as the various dimension limits have been worked to so as to have the shell slightly overweight, it is a simple matter to remove this extra weight from the base The shell is driven by a threaded arbor in the nose, and the base end supported in a steady rest, four C.M.C. 18 in. lathes being utilized for this work and facing off the rough base plates.

Marking and Banding

These operations are performed in the same machine, which is of the pneumatic type and was designed and built in the shop, see Fig. 12. The machine is here shown marking the base of 60 pdr. shells, the various letters being held in position in a plate above the inverted shell, the

FIG. 12. SHELL BANDING PRESS WHICH IS ADAPTED FOR MARKING THE BASES ALSO.

nose of which rests in a suitably shaped die, which in turn is forced upwards with considerable pressure by a large diameter piston working in the cylinder underneath the table. The operator's right hand is on the end of a long lever which operates the controlling value in the air pipe just above his foot. When used for compressing the copper driving bands , the supporting die is removed and the shell allowed to descend to a point where converging jaws are brought to bear on the band, these jaws being forced toward the centre by a series of radial toggle levers.

Final Operations

Two C.M.C. 26 in. lathes fitted with Bertram attachments now machine the bands to size and profile, after which the shells having passed final inspection are lacquered, baked and painted, the final work being the fitting of the shipping plugs and packing the shells in regulation shipping boxes. The painting is done on a special machine shown in Fig. 13. Temporary plugs in the nose of the shells allow them to be set on tilting studs, so as to be revolved by friction drive from the large diameter plate in the centre of the machine. The paint pot is supported on a swinging support which allows the operator to move round the machine. When a shell is painted it is swung out of contact with the driving plate and is then easily removed, to be placed in the drying racks at the left of the picture, these being heated by hot air.

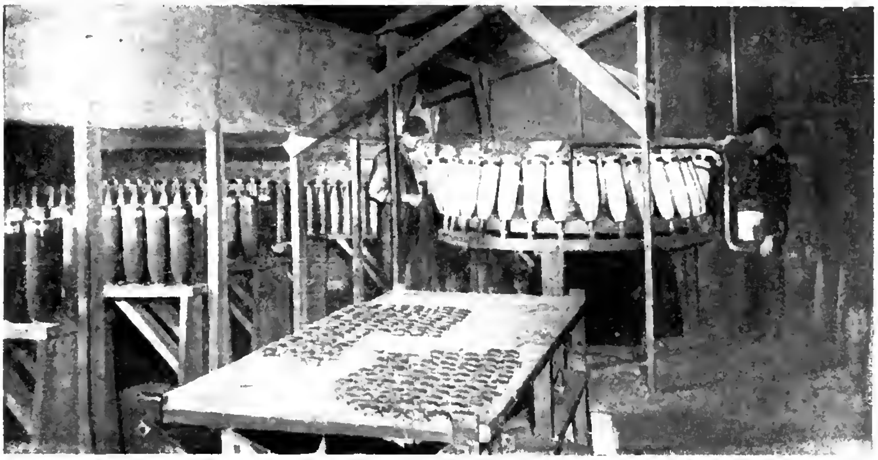

FIG. 13. SHELL PAINTING MACHINE WITH MULTIPLE FRICTION DRIVE.

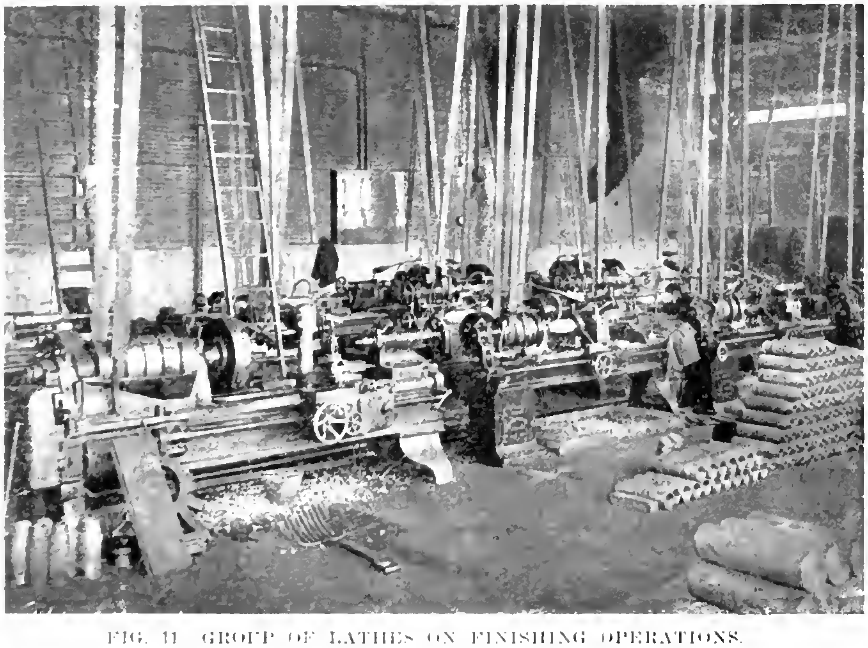

FIG. 11 GROUP OF LATHES ON FINISHING OPERATIONS.

War Trade Committee.—With the object of assembling and collating information bearing upon the new trade situation created by the war, the Dominion Government has appointed a war trade committee. It is to be purely interdepartmental and wil consist of Sir Joseph Pope, under-secretary of State for External Affairs; John McDougald, C.M.G., commissioner of customs; F. C. T. O'Hara, deputy minister of Trade and commerce, and one other, the committee having power to enlist the co-operation of certain other officials.

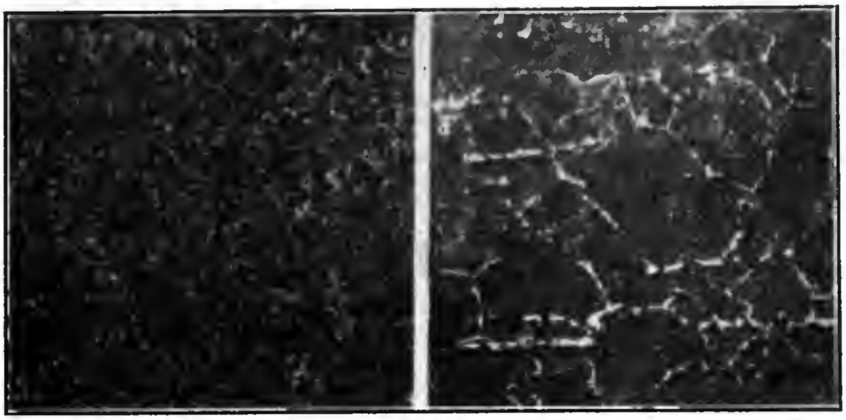
HEAT TREATMENT OF STEEL

By "Melter"

AT the moment, when the majority of manufacturers in the mechanical trades are engaged in turning out munitions of war it may be of interest to explain the "why and wherefore" involved in the heat treatment and working of alloy, and steel materials. Primarily a comprehensive understanding of the fundamentals of metallurgy must be acquired and the success of the practical results obtained will largely depend on the degree of knowledge attained in this very important branch of mechanical engineering.



A—UNANNEALED. B—ANNEALED.
Magnified 50 Diameters.

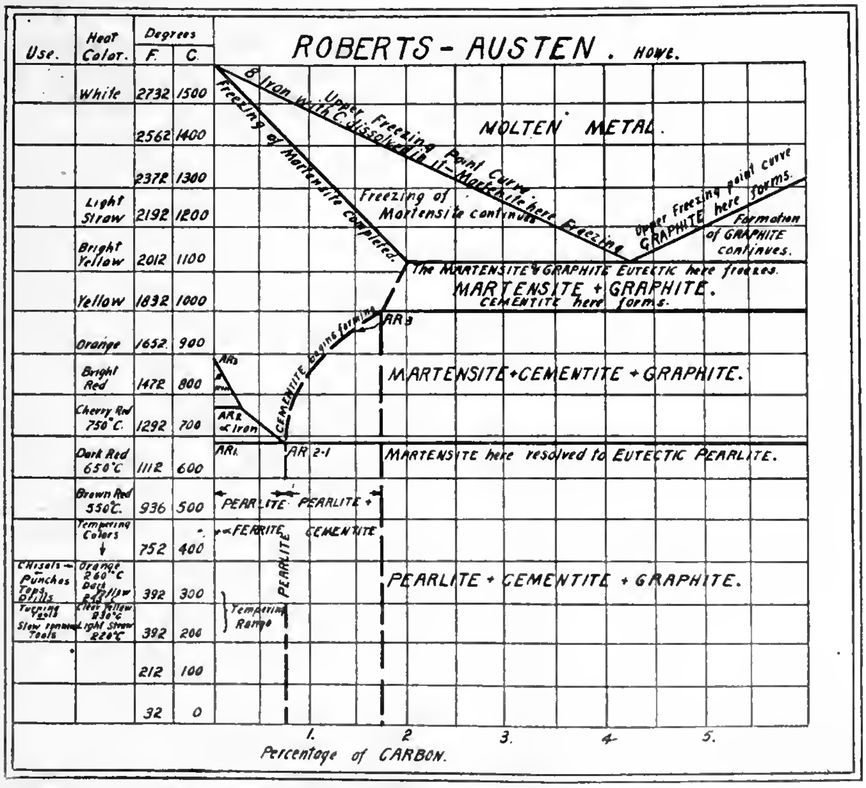
Steel-Making Processes

Steel should be considered first as it is the product most widely used. It is principally made by four different methods—Bessemer, Open Hearth, Crucible and Electric. The Bessemer process is not very largely used now except for special purposes—as making sheet metal. The Crucible process is extra and more expensive than Open Hearth or the Bessemer and the product is used where an extra fine material is required such as for tools or dies. Electric processes are rapidly emerging from the experimental stage, but the product is still somewhat expensive.

The Open Hearth process is used in making steel for shrapnel shells. It is the most widely used of all processes, and while there has been a lot of discussion as to whether the acid or basic open hearth process is the better for all practical purposes there is no vital difference. Results of exhaustive published tests have shown acid open hearth to be slightly the superior.

The qualities of the steel which may be in use do not therefore depend so much on the type of furnace used in the manufacture, as on the ingredients in the steel and the way in which the steel is manufactured.

Carbon is the most important element, as on the quantity of this element, and the state in which it exists, depends the distinction between wrought iron, cast iron and steel. Wrought iron is pure iron (or ferrite as the metallurgists call it) crystallized in many shapes and forms. In addition to ferrite there are elongated particles of slag. Low carbon steel is wrought iron without the slag and in addition to the ferrite there is a little more carbon. Now carbon does not exist as carbon but combines with the iron forming a carbide of iron, and it is on the state of this carbide that all the properties of steel depend. This carbide when combined with ferrite in segregated areas and not disseminated through the mass as it is in mild steel is called pearlite from its appearance under the microscope.



ROBERTS-AUSTEN DIAGRAM ILLUSTRATING EFFECT OF HEAT ON IRON WITH VARYING PERCENTAGES OF CARBON.

Carbon may be introduced into steel up to a certain point when all the ferrite will have combined with it and the whole will be pearlite (as it is in tool steel). If still more carbon be introduced there will be an excess of the carbide. This saturation point occurs when about 0.8 per cent. carbon has been absorbed.

Effects of Heat

The results obtained by heat treatment are caused by critical changes which occur within certain narrow temperature limits. These limits are called calescent points sometimes written Ar. 1, 2, 3, and Ac. 1, 2 3 and represent points where definite charges take place. These changes are chemical structural, and physical, and when the temperature is ascending the pearlite becomes broken up, it's carbides going into solid solu-

tion in the ferrite. It will be noted that some steels have more than one of these points if reference be made to the Roberts Austen Diagram.

The term annealling means breaking up these dissolved carbides and distributing them through the mass, and to do this properly, slow cooling from slightly above the decalescent point is necessary. If on the other hand steel is heated above these points where all the carbides are in solid solution and cooled very quickly a new state of matter is obtained. It is this new molecular formation called Martensite which imparts the hardness to steel and by referring again to the diagram it will be seen just how high a temperature must be attained for varying amounts of carbon to obtain a certain structure. It must be borne in mind however, that if it is desired to anneal or harden steel it must be heated just above the critical temperature. The higher it is heated above this point the courser will be the grain. Slow and undisturbed cooling from just above the critical point produces the finest grain.

Photograph A. shows a piece of steel heated considerably above the critical temperature and B. shows a piece cut from the same bar, heated just above the decalescent point and allowed to cool slowly.

To sum up:—1. Steel heated above the critical point has the finest possible structure at that point, but the further it is heated beyond it the larger the grain size.

2. For any given temperature above the decalescent point, a certain grain size is normal.

3. When cooling occurs after being overheated, the grain is not reduced in size and in order to make any change in the structure the steel must be reheated slightly beyond the decalescent point.

Influence of Carbon

As we have seen from the above that the qualities of steel depend largely on the treatment and state of the carbon it may be of interest to look at Table 1 where the results are given of tests with varying percentages of carbon, on commercial bar steel made in Canada.

Table 2 gives results which demonstrate clearly the great benefits which may be obtained through suitable heat treatment.

TABLE 2.—EFFECT OF HEAT TREATMENT.

Carbon	Manganese	Heat Treatment	Elastic Limit	Elongation in 2 inch	Reduction in area
.05	.05	None	32,020	42.5	53.8
.18	.40	Annealed	39,460	35.0	62.6
.18	.40	Heated 1650)) Oil quenched .... Drawn 750)	45,390	33.0	64.6
.18	.28	Annealed	43,010	34.0	63.4
.26	.28	Heated 1650)) Oil quenched .... Drawn 975)	52,230	28.0	65.3
.35	.50	Heated to 1500-1550 ....)) Drawn 600 to 1200 ....)	45,000 to 80,000	....	....

The rate of quenching has a very important bearing on the physical properties, for if the cooling is not rapid we do not obtain the desired martensite but an intermediate structure which is not so hard.

Quenching Mediums

Experiments have shown that different quenching mediums give different degrees of hardness, tensile strengths, tc.

Effect of different oils on pieces cut from shrapnel shell forgings.

Carbon %	Tensile strength lbs. per sq. in.	Elongation in 2 in. %	Kind of Oil.
.32	129,000	16	Seal oil
...	118,000	20	Rape oil
...	134,000	18	Seal oil
...	125,000	20	Rape oil

The oils used showed the following physical properties:

	Viscosity at 60° F. Saybolt seconds	Specific gravity
Seal oil	131	.924
Rape oil	261	.915

The desired effects of quenching mediums seem to be better obtainable from those liquids which possess high specific gravity, low viscosity and the power of creating as little vapor as possible thus allowing the liquid to be in more intimate contact with the steel, and exert its cooling effect more efficiently. The size of the test piece has an important bearing on the results obtained. In commercial practice very often the time is not taken to heat a piece slowly, uniformly and for a sufficient period for the heat to soak into the center of piece without overheating the exterior.

Some tests have shown that when the work has been proceeded with on a commercial scale, even with the greatest care there will be a variation of as much as 33 per cent. from results obtained with a half inch diameter and a 1¾ in. diameter test piece. Consequently if a larger piece of steel is to be used a higher and more careful heat should be given.

Temperature and Mass

Recently published results of investigations give some interesting data on the effect of temperature and mass. These results show that for each increase of 1-16 in. diameter the temperature should be increased 5 degrees. Some heading and indenting punches for brass cartridge cases were made of 1.25 per cent. carbon steel, water quenched, but the metal took a permanent set under working conditions so that the only way in which results could be obtained was to build up the punches with 1 in. thick sections bolted together. This effect of treatment on mass causes specifications to call for location of test pieces as is done in shrapnel cases. For example nose of shell being of a different thickness to body, the heating temperature and effect of quenching medium would give different results.

The effect of overheating mild steel shows that for the first 100° F. overheat there is a reduction in foot lbs. resistance on an impact test, of 50 per cent., and for each further increase in temperature of 100° there is a reduction of 60 per cent., 90 per cent. and 99 per cent.

TABLE 3.—EFFECT OF HOT WORK AND QUENCHING ON MILD STEEL.

Treatment	Tensile strength lbs. per sq. inch	Elongation in 8 inch
Normal	55,000	13%
Worked at 1150° F. air cooled slowly	65,000	13%

Effect of Hot Water and Quenching on Mild Steel

Great care should be taken in handling steel at a blue heat, say 400° to 650° F. for it has been proven when elongated 1.7 per cent. that the brittleness has been increased 33 per cent. Table 4 shows some interesting figures on tests made at different temperatures.

TABLE 4.—HOT AND COLD TESTS ON IRON AND STEEL.

Material	Temperature	Diameter	T/s lbs. per sq. in.	Reduction in area	Elongation in 8 in.
				Elongation	Reduction

PIECE WORK SYSTEMS—II.

by R. R. Clarke

IN the foundry, bases for three different system of piece-work arrangement are practicable, namely: Set day's work and proportionate increase in daily earnings for increase in output; set price per flask and set price per individual pattern.

Remunerating IncreasedDay Work Output

The first-named system retains features of the day-work idea. In foundries employing it moulders are usually paid so much money for so many hours' work, as for instance $3.60 for 9 hours, the management stipulating that so many, say 10 flasks or pieces, off a certain pattern constitute a 9-hour day's work. The moulder is at liberty to reduce the time in making these castings to whatever figure he is capable or to increase the number of pieces or flasks when demands in the foundry justify regardless of the number of hours falling within the prescribed figure. Following out this system moulders make what they term a day, a day and a quarter, a day and a half, etc. This system is extensively used and finds its most useful application where the larger castings are ordered in extensive quantity. It is, however, more or less limited in application, and not an entirely satisfactory universal system. In a jobbing shop where small and mixed work in erratic quantities predominates, its use presupposes more or less difficulty.

Price Per Flask

The price-per-flask system is kindred in execution to the set day's work method. It consists in fixing the price on a basis of flask dimension as for instance a flask 16 in. x 16 in. x 10 in. deep over all would pay 20 cents; 24 in. x 24 in x 12 in., 30 cents etc.

Such a system has been tried and discarded by more than one firm. Its chief difficulty consists in the fact that it determines wages on the basis of sand handled rather than amount of castings produced. Especially is this true in the mixed work. The loss in metal melting is a feature of brass foundry operation sufficiently important to warrant that every gate be made to produce its maximum of casting output. This gate remelting loss constitutes a necessary evil in consequence of which the wide-awake foundryman will reduce this loss to a minimum by making every gate used produce its full quota of merchantable castings.

And therein is discovered a serious weakness of the price-per-flask system. Moulders will not take sufficient interest in filling the flask to its pattern capacity unless constantly watched and constant watching breeds constant trouble. We know of one foundrry where the contention arising from this feature alone became so monotonous that the system was abandoned. In the sum-total of the day's work the man's worth is the quotient arising from a division of his production into his wages regardless of sand handled and the failure of this system to take care of this feature is sufficient evidence to warrant serious consideration beore adopting it.

Price Per Individual Pattern

From these systems and their difficulties we turn to a consideration of a more congenial practice, namely, the price-per-individual-pattern method. This to our mind is the all around logical system. It consists in determining the price per casting from a consideration of its size, weight, and moulding complexities, and paying for those castings only which satisfy the reasonable demands of a close inspection. It puts the question of wages, output, and casting and gate melting loss fairly and squarely up to the man. If good, he will make good, and if not the firm will have little to regret at his departure. It is the practicability of universal application along with the incentive given the man to produce to full gate and flask capacity good, solid, castings that recommends this system to preference, it of course being understood that all opposition will be courteously yet firmly silenced.

This system, employed in a very progressive foundry known to the writer, and to the maximum of advantage is subject to the following method of control: First, the patterns, all of which are given designating numbers, are taken from their recorded placement, tagged with a service tag, and then given to the moulder who preserves the tag keeping his daily record on the back thereof. On his daily and dated service card the moulder states the number of pieces made from each pattern and computes the earnings of each, totalling the amount thus computed on the bottom of his card. He then signs his card and deposits it in the office at the end of each day.

From each days' card a daily and dated inspector's card is made, recording each man's work, and then handed to the inspector who counts and inspects the castings, placing the amount of good castings found opposite the amount the moulder claims to have made. Completing this card, the inspector shows each moulder his itemized account to acquaint him with his loss and then hands the card back to the office clerk. From the amount found, the clerk notes any and all differences between that and the amount claimed, computes the value of these differences and adjusts the service card correspondingly. In executing this method it might be well to remark that clear and concise records of all piece-work prices are kept, that the prices put on the card by the moulder are carefully checked against these records and that the computations on all cards are carefully gone over to detect and adjust any errors that may have occurred thereon. It might be of interest to remark further that the complementary systems in this foundry are so perfected that each day's work is cleaned up and taken to the shipping room by afternoon of the day following its making, thus eliminating all possibility of getting one day's work mixed up with another.

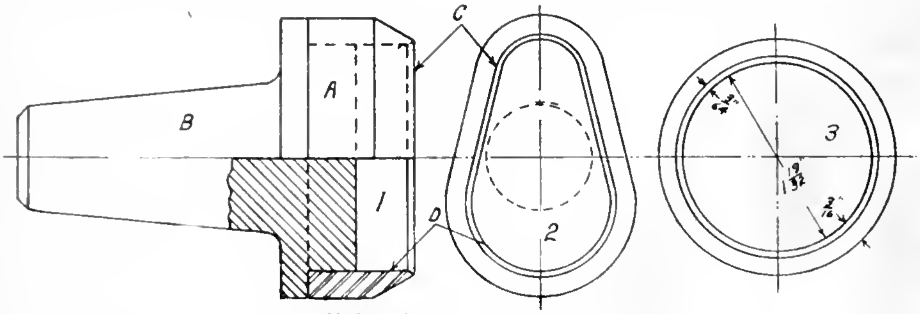
As to the qualifications of the inspector our notion is that he should be a moulder or one acquainted with the principles of the trade, thus enabling him to give just decisions on the cause of defect in castings, and to arrive at the seriousness of the defect through the auxiliary knowledge of any error in making. A heavy scale on the side or bottom of a casting when chipped off may evidence no surface defect, yet the moulder knows that sand dislodged therefrom is somewhere hidden in the casting. The quantity of dirt, the position of casting and the vicinity of clean metal demanded will be more accurately determined and mean more to the trade-knowing man than to one not acquainted therewith, howsoever bright he may otherwise be.

AN ODD-SHAPED PUNCH

By J. R. Hamilton.

WHEN a number of odd-shaped holes are required to be punched or cut in thin sheet metal, it is often a very expensive and tedious operation to perform with a small chisel. If there are only a few, this method may be very satisfactory; and on the other hand, if there are a great number, it may be profitable to construct a special punch and die. However, in some instances the number is not sufficient to repay the cost of a punch and die, and where the opening is small it is often advisable to construct a special punch that will insure the holes being of uniform size and shape.

The accompanying sketch shows the method adopted in making a small hand punch to cut an opening in tin, of a shape shown by the line C. It was decided to make a cast steel ring and shrink it on a machine steel shank. By carefully measuring the outline of the opening it was found to be approximately 5.3 inches. The diameter of a circle of this circumference would be 1 22-32 inches. Allowing an inner bevel of 3-64 inch, as shown at 3, the internal diameter of the ring would be 1 19-32 inches.



AN ODD-SHAPED PUNCH.

The ring was then turned in the lathe to the required dimensions and bevels, and afterwards heated and formed to shape. The shank was then shaped and filed a little large for the shaped ring. The ring was then finished and hardened and forced on while at the redrawing temperature. Several similar punches were made in this way, and proved very efficient.

EXTINGUISHING SMALL FIRES FROM PETROLEUM SPIRIT, ETC.

THE British Fire Prevention Committee have recently carried out a series of tests, the results of which tend to prove that sawdust intimately mixed with bicarbonate of soda and applied in bulk has certain advantages over sand and similar materials as an extinguishing medium for comparatively small fires occasioned by the ignition of the vapor of petroleum spirit (petrol) and other inflammable liquids.

When sawdust is applied to the surface of a liquid it will float for some time thus excluding the oxygen of the air and smothering the fire. Ordinary sawdust, as obtained from sawmills, is the most suitable for this purpose. It must be free from shavings and chips of wood, but it does not require to be either specially dried or to contain added moisture. The addition of bicarbonate of soda although not essential is advantageous. Under the action of the heat from the burning liquid, carbonic acid gas is given off from the bicarbonate of soda adhering to the floating sawdust and accordingly close to the source of the fire. The gas given off under such circumstances slightly assists in extinguishing the fire.

An effective proportion of bicarbonate of soda to sawdust is 10 lb. to 1 bushel (or, say, 20 lb.) of sawdust. Any form of bin, such as a dust-bin can be used, but a specially suitable bin can be made of sheet iron, 24 inches square, 3 feet 6 inches high, 18 inches square on top, the sides sloping slightly. The top should be arranged for filling purposes, and at the bottom of one side there should be provided a hinged door 16 inches wide and 21 inches deep. Such a bin would hold about 8 bushels, and it should be kept in a convenient and easily accessible position as near the petroleum spirit, etc., as possible. The mixture to be thoroughly effective should be applied not only in bulk but rapidly and systematically, the object being to produce what may be termed a lateral "curtain or scythe effect.

MAXIMUM PRICES OF IRON IN GREAT BRITAIN

THE question of the price of material used and produced in Britain's iron and steel industries has been under the consideration of the minister of munitions for some time part; and, after consultation with the representatives of the principal trade associations, the following maximum prices for the various products have been fixed until June 30, 1916, and thereafter until further notice.

The makers may sell for delivery after June 30, 1916, on the understanding that the fixed maximum prices ruling on the first day of any month during the period of the contract will apply to all deliveries made during that month. These maximum prices are based upon the abnormal costs and conditions now prevailing, and must not be assumed to be indicative of any difference in relative values which may have obtained in the several districts before the war and may obtain again after the war. This intimation must not be taken to authorize any sale or purchase or other dealing prohibited under the Defence of the Realm Regulations:—

The administration of the South African Railways has decided to provide a new erecting shop at Salt River, near Cape Town, at a cost of approximately $115,000. This will enable the heavier type of locomotive now in use to be handled with greater expedition. Machinery and plant will be required for the engine shops.

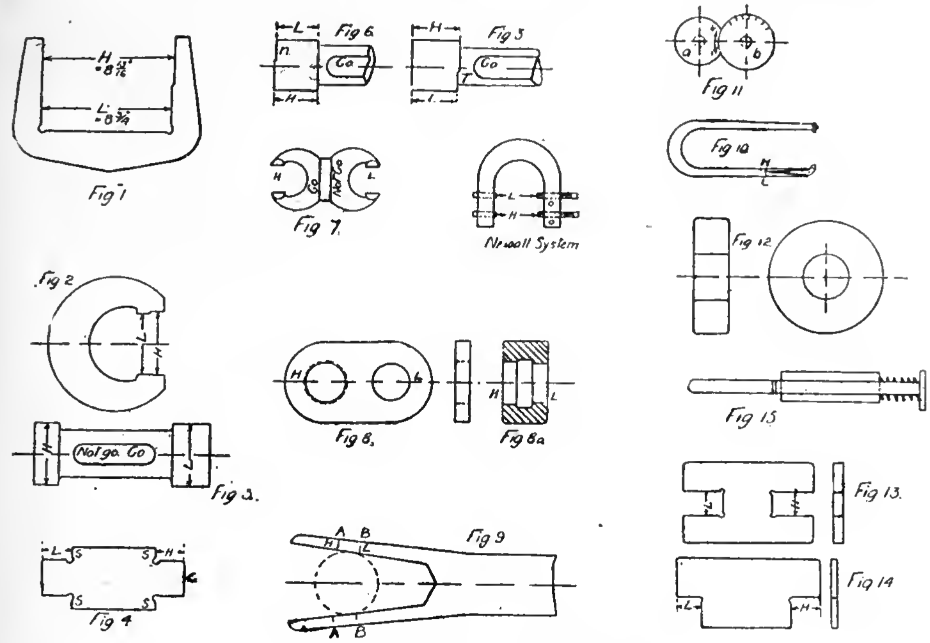
NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

LIMIT GAUGE PRINCIPLES AND PRACTICAL APPLICATIONS—III.*

By W. H. Booth

As to material of gauges, this may be of cast iron, especially in large sizes. Hard tool steel may be used for small gauges, especially if these be unhardened screws. Drop forgings of mild steel are much used, and so are gauges cut of plain flat plates. Mild steel gauges are finished somewhere near to size, and are then subject to a case-hardening process on the gauging parts. Enough only is left to grind and scrape to a true finish. Cast iron has the advantage of cheapness and also of brittleness, breaking if allowed to fall on the floor, and so avoiding a possible large



LIMIT GAUGES FOR VARIOUS SERVICES.

number of spoiled pieces of work which may follow upon a fall on its edge of a more malleable gauge of mild steel, and a consequence of a slight change of form.

It should be possible to cast iron gauges in a chill, or to cast them in dies, so that any little grinding will finish them within the thickness of the chilled surface. Cast gauges should be suitably tumbled so as to remove any tendency to change form from the influence of internal stresses. The same may be said of drop forged steel, for a drop forged steel gauge will begin to move from the first, and will move for two years before settling down to a fixed size.

In gauge-making, there must be no attempt to close or open the jaws of a gauge by light tapping or opening with a hammer. This sets up surface stresses, and the rough hands of a workman very speedily grind away the surface and relieve the stresses, and the gauge moves at once. These small movements only become of importance in the case of fine work requiring fine limits and small tolerances. They are mentioned to show how special the work of a gauge-maker has become. They at least justify the manufacturer to stock large quantities of the more usual types of gauges so that the final finish can be added after at least the greater part of the stress movement has taken place.

Like all other articles of commerce, gauges must be made in quantities, and the gauging parts machined together, the jaws of a number of gauges being milled out while the gauges are fixed and clamped side by side in a jig, in which also they must be ground nearly to the finishing dimension. Cylindrical gauges cannot so be made, for they must be turned and ground as separate units, and usually they are more costly because of this more individual treatment.

Measuring Large Holes

For measuring larger holes, instead of discs being employed, the spherical end measuring rod is much used. A rod of this description is finally ground to length in a machine in which the rod is rapidly rotated upon its longitudinal axis, and the frame which carries it is given a rocking movement in the horizontal plane, the end of the rod being presented to a rotatory grinding disc. Thus, a 1-ft. spherical end measuring rod is part of a 12-in. sphere cut through its centre. Its advantage is that it finds its true place in gauging a bored hole, and there is far less liability to error than when a pointed rod is used. End rods vary from 1/4 in. to 3/4 in. diameter according to the diameter of the holes to be gauged. They are also usable to check lengths where it is possible to set their ends to a square projecting from the line of measurement.

In Fig. 8 is seen a very usual form of double-ring gauge. In grinding these in a lathe the piece is out of balance, and must be balanced by adding a weight. In many instances such a gauge would be better made to the form Fig. 8a.

Fig. 12 is the usual form of standard or one-dimension ring gauge. Fig. 13 is a cheap form of thin plate gauge for measuring diameter or breadths and lengths. Fig. 14 is a depth gauge more often used with the dimensions across the wide piece, and in double form, back to back—for gauging the depth of recesses. Fig. 15 is a depth gauge with a moving spindle to show depth by means of lines placed across the spindle, as shown, for certain conditions of visibility, or otherwise modified to suit the purpose in hand.

There is no particular art in devising a limit gauge beyond the selection of the dimensions on the piece to be gauged, so that the number shall be a minimum, and yet no required dimension shall be wanting. A good designer will, as far as possible, lay out his designs to involve a minimum of gauging. For this reason, when a design has been evolved for any piece of work, it does not follow that the drawings will best fit shop conditions, and in the best conditions of manufacture it may be necessary for a special man to redraw the work without changing any part of the design in respect of centres or parts which move together. In a general way, that design is best which can be made with a minimum of dimensions on the drawing.

As a broad principle, the gauging of a machine consists in determining the distances apart of the centre points. Details are separately gauged for diameter and thickness. Many parts need no gauging; they are finished from fine castings and cannot go wrong. Small parts made on automatics are beyond gauging, except for an occasional test of one part in each few hundred, so as to indicate any departure from truth.

*From a paper read before the Association of Engineers-in-Charge.

Designing Gauges

There is a special art in designing gauges so that they shall produce the class of work required. This requires a knowledge of shop work and of the class of work required. Considerable judgment is needed to fix the limits so that results are satisfactory. One item alone need be named to show the difficulty which may arise. It often happens that, for two parts which have to work or fit together, the limits from the nominal sizes may be so wide, compared with the fit diffierence, that the maximum dimension which the smaller piece may receive will actually be greater than the minimum dimension of the larger piece. Thus a shaft or spindle may come out larger than the bore for wheel which is to run on it.

This point has already been alluded to, and is one which will become over-prominent when the workmen are unaccustomed to the limit principle, and, as they always will do, insist on working right up to one limit. It is for this reason that special insistence is laid on workmen acquiring as soon as possible the courage of their skill. When they have acquired this, it will rarely happen that well-designed gauges, even with crossed or overlapping limits, will give non-assembling results. Some little selective assembly may be occasionally desirable, but there will be little absolute rejection of parts.

APRIL RAILROAD RETURNS

COMPLETE RETURNS of the gross earnings of the three big Canadian rail roads in April show extremely satisfactory conditions, the aggregate being the largest of any month so far this year and the gain over the corresponding month a year ago the largest, both actual and percentage, yet reported in 1916.

Owing to the fact that Canadian Northern returns now include figures which were kept separate from the system's earnings up to last summer, too much is not to be made of the fact that the April total this year is the largest ever reported for the three systems combined. What is clear is that, with due allowance for the difference in the C. N. R. figures, April 1916 gave results about midway between the totals of April, 1912, and April 1913, when a new stage in the expansion of Canada was culminating. Taking the figures as available the $18,077,805 total for April this year compared with $13,118,678 in 1915, $15,417,367 in 1914, $17,906,556 in 1913 and $16,882.202 in 1912.

Grand Trunk earnings in April this year exceeded those of the same month in either 1912 or 1913, C. P. R.'s were about $400,000 to $900,000 less. C. N. R's ran about $1,100,000 to $1,200,000 higher, but then, as already noted, they take in figures from a part of the system not included in the 1912-13 period.

Total gross earnings of the three systems combined, through April are tabulated below:

Week	Earnings.	Increase.	P.C.
First	$4,314,486	$1,083,166	33.5
Second . . .	4,270,405	1,241,047	40.9
Third	4,036,961	1,101,889	37.5
Fourth . . .	5,455,953	1,533,025	39.1
Total . . .	$18,077,805	$4,959,127	37.8

URANIUM IN TOOL STEEL

THE latest development in the tool steel industry, says the Iron Age, appears to be the application of uranium as an alloy in varying quantities. In the accompanying table is shown a number of comparative tests of tools made from uranium high-speed steel as compared with regular high-speed steel. The tools marked U are uranium steel tools; those marked B, C and D are regular high-speed steels. The tests were made under the direction of the Standard Chemical Co., Pittsburgh, at the works of the Mesta Machine Co. and other large users of tool steel. All uranium tools were ½ x 1½ in., except No. 8-U, which was 1 x 2 in. The standard tools were all of larger sizes, the smallest being 1 x 2 in.

GLAZING OF GRINDING WHEELS

WHEEL glazing is one of the commonest troubles the grinding wheel user has to meet. A wheel glazes when the points of the abrasive grains wear flat without the surrounding bond being disturbed. Its causes and remedies are as follows:

Wheel too hard for the work in hand, therefore dressing is only a temporary remedy. A softer wheel must be used to cure it effectually.

Wheel running too fast; having the effect of making the wheel appear harder. The speed should be altered to between 4,000 and 6,000 revolutions per minute.

Too much surface contact between wheel and work; therefore, if possible the work should be jockeyed in front of the wheel so that at any one moment a small surface only is presented to the wheel.

Not enough pressure of work on wheel; requiring in consequence more pressure so as to disturb the bond and dulled grit.

Using wheels bonded with rubber, cement or shellac where such bonding is not desirable; the only remedy being frequent dressing, if impossible to change the wheel.

Variation in hardness of material being ground; this is unavoidable and the only remedy is dressing as required.

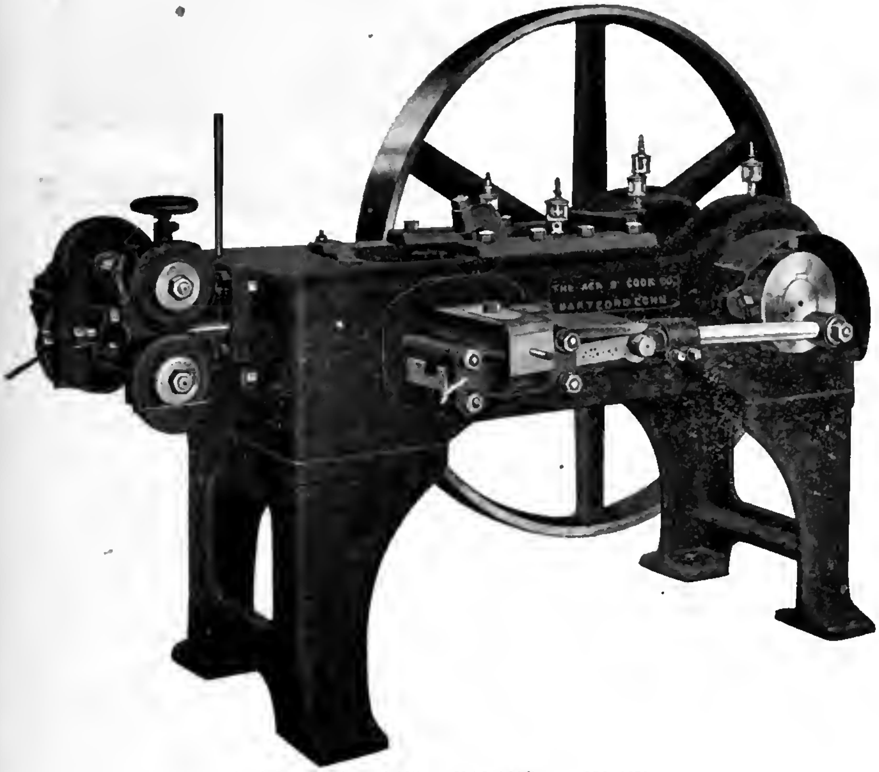
Tool	Feed, In.	Speed, Ft. Per Min.	Depth of Cut, In.	Remarks
Cutting 0.50 per cent. carbon 12-in. shaft:				
No. 1-U	1/16	75	¼	Went over once distance of 14 in. On second lay went 3 in.
B	1/16	75	¼	Went distance of 4 in.
D	1/16	75	¼	Went distance of 1 in.
Cutting 8-in. shaft 7 ft. 5 in. long:				
No. 1-U	1/16	51	⅝	Went over twice. Cut changed to ⅜ in. on second turn.
C	1/16	35	⅝	Did not go 1 in.
Cutting 6-in. shaft:				
No. 1-U	1/32	75	⅝	Ran 18 in.
No. 2-U	1/32	75	⅝	Ran 13 in. Speed increased to 90 ft. per min. and ran 11 in. Tool still good.
B	1/32	75	⅝	Ran 11 in.
Cutting 10-in. shaft:				
No. 4-U	1/16	60 to 65	⅝	Went 8 in.
No. 2-U	1/16	65	⅝	Went 4 in. Speed increased to 80 ft. per min. and went 3½ in.
No. 1-U	3/64	55	5/16	Went 16 in.
B	3/64	55	5/16	Went 2½ in.
No. 5-U	3/64	55	5/16	Went 15 in.
Cutting 12-in. shaft 22 ft. long:				
No. 8-U	1/16	45	⅝ to ¾	Ran 87 in. Most of time the nose of the tool was right on scale.
Cutting 12-in. forging:				
No. 8-U	1/16 to 1/10	38	15/16	Went 127 in. Time, 3 hr. Speed increased to 65 ft. per min. after tool had gone 105 in.
No. 8-U	1/16	60	1 1/16	Ran 12 in.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

SOLID DIE RIVET HEADING MACHINE

THE illustrations show a solid die header or rivet machine and a patented friction feed for the wire used in such machines. The Asa S. Cook



SOLID DIE RIVET HEADING MACHINE.

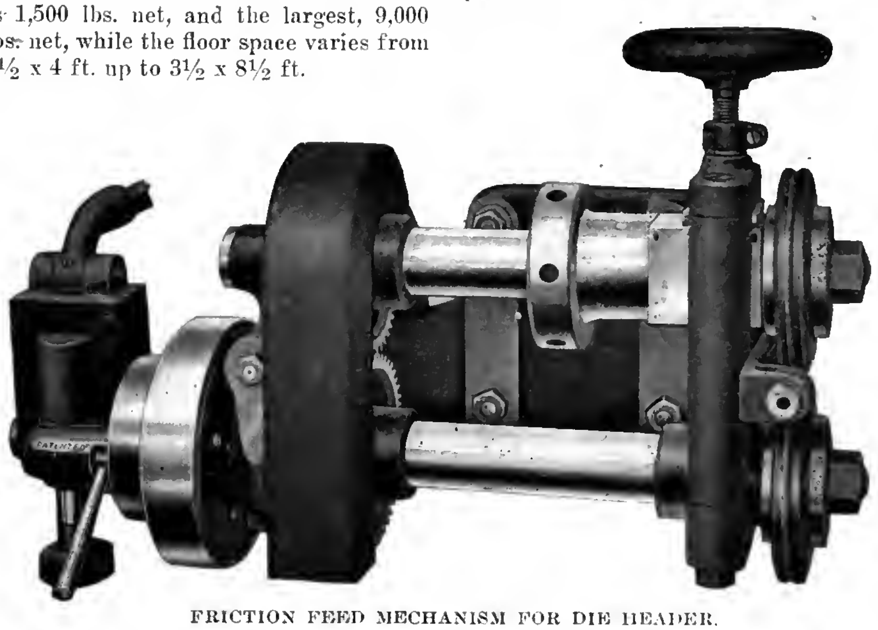
Co., Hartford, Conn., builds a line of five of these machines, which are used principally for making round, oval, filister or similar shaped heads, which are produced in finished sizes and do not require subsequent trimming or shaving.

The production capacity on solid die machines is 150 per min. for the smallest header and 60 per min. for the largest, the diameter of wire varying from 1-16 in. to 7-16 in., and the length fed from ¾ in. to 3 in.

By means of the friction feed, the operator is enabled to regulate—while the machine is in motion—the amount of stock necessary to make a full head without any fin or flash on the edge of the head, and to make a full perfect head so long as the punch and dies are in good condition. By doing so, the pressure on the punch and dies is reduced to a minimum, resulting in their life being much longer. In the case of the blank sticking in the dies, there is no chance of breakage, as the friction is adjusted so that it will slip in case of unusual strain.

Advantage over the ratchet type of feed is claimed, because the circumference of a ratchet wheel cannot be equally spaced for different lengths of blanks or rivets with consequent waste of stock. The heading machine is so constructed that the cut-off does not work while there is still any pressure on the punch.

The weight of the smallest machine is 1,500 lbs. net, and the largest, 9,000 lbs. net, while the floor space varies from 2½ x 4 ft. up to 3½ x 8½ ft.



FRICTION FEED MECHANISM FOR DIE HEADER.

CENTRIFUGAL LUBRICANT PUMP

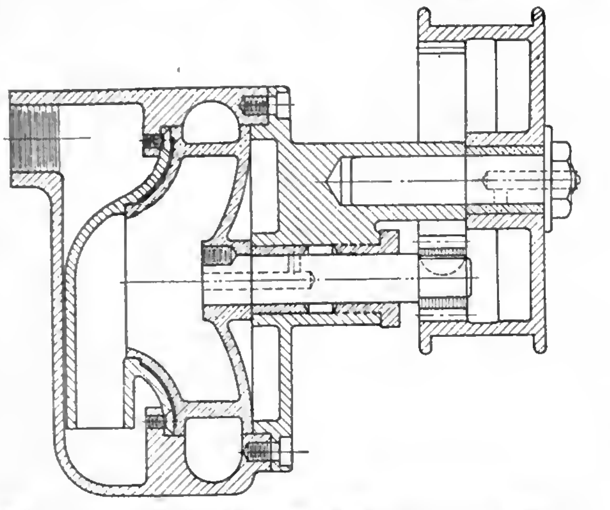
THE peculiar requirements of machine tool lubricant pumps, i.e., ample volume of fluid without unnecessary pressure, are satisfactorily fulfilled by the Fulflo lubricant pump which has been placed on the market by the Cincinnati Lubricant Pump Co., Cincinnati, O.

The pump is of the centrifugal type, and is of compact design, possessing a capacity, according to speed, from 5 gallons per minute at 250 revolutions, to 18

CENTRIFUGAL LUBRICANT PUMP FOR MACHINE TOOLS.

gallons at 400 revs. per min. Increased flows or heads may be had by increasing the speed. As shown in the line drawing, the construction is very simple, the only working part in the liquid being the impeller, which is of such a shape that chips, grit, and other foreign substances pass through freely without detriment to the efficiency of the apparatus.

As a result of the free passageways, it is not necessary to use strainers with this pump, and the manner in which the internal suction pipe is inverted provides a trap arrangement which acts as a self-primer, thus dispensing with the use of check valves, etc., the only valve of any kind used in connection with it being the stop-cock, with which the operator controls the flow on the work, the centrifugal principle allowing the pump to adjust itself to any variation in flow without the use of a relief valve.



CONSTRUCTIONAL DETAILS OF PUMP SHOWING DETAILS OF GEAR DRIVE AND STUFFING BOX ON IMPELLER SHAFT.

STEAM SOOT BLOWER ARRANGEMENT

A SYSTEM for removing soot and fine ashes from the heating surfaces of vertically baffled water-tube boilers, and based essentially upon projecting powerful oscillating steam jets into, through and laterally across the spaces between the horizontal rows of tubes in planes parallel to the pitch of the tubes, is now being offered by the Bayer Steam Soot Blower Co., of St. Louis, Mo.

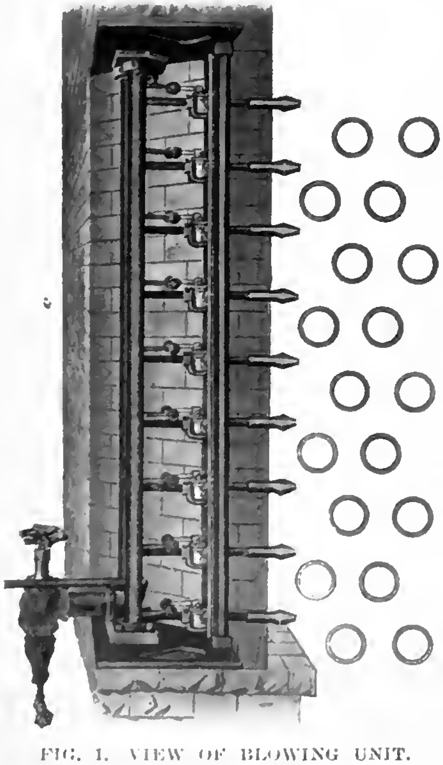


FIG. 1. VIEW OF BLOWING UNIT.

The soot blower has been so designed that the parts can be placed without changing or cutting brick work and walls, the original cleaning openings and internal wall angles in the side of the boiler being ample to permit a wide swing of the nozzle heads. The nozzles are divided into groups or individually controlled blowing units, Fig. 1, each of which served a gas pass or compartment, and is fitted into the cleaning pockets originally provided along the side wall for hand cleaning. The individual units receive their steam from a supply line passing below the blowing units, and having a drain at the lowest point to permit the removal of any possible condensation just before each blowing operation.

The action of the jets through their direct force and expansion of the steam is to create intense momentary drafts that loosen the objectionable particles and push and pull them out of the gas passages into the stack. The method of imparting oscillation to the nozzles will be understood from Fig. 2. Each blowing unit has a riser connected to the steam line, and controlled by its own valve. Short branches extending inward from the riser connect the riser with swing joints, the moving members of which are connected through nipples to the three-way nozzle heads within the furnace wall. A vertical rocking shaft located at the side of the riser connects with the moving members of the swing joints through sets of links and levers. By rocking the shaft alternately from right to left, the entire series of nozzle heads is swung back and forth, the steam being delivered in three separate powerful jets from each nozzle which agitate and remove the soot and ash deposit.

The type of swing joint used, in addition to permitting easy installation, inspection and overhauling, may be brought squarely up against the cover shield which closes the cleaning pocket, and is tilted to the same pitch as the tubes. This permits the steam to sweep at all points within the plane spaces between the tubes, which is essential to thorough cleaning. The swing joints are bolted to a metal cover shield which fits against and is clamped to the two strips on the wall plate, the cleaning pocket being thus permanently air-tight. The unit is located when the shield is clamped into place. Adjustment of the units in permanent position can be completed while the boiler is in service, and the rest of the installation is merely a matter of piping.

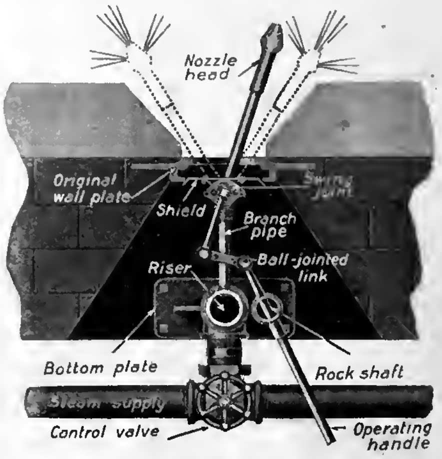

FIG. 2. MECHANISM FOR OSCILLATING BLOWER NOZZLES.

STIMULATING PRODUCTION OF FORMER GERMAN MADE GOODS

INTIMATION was made in Parliament on May 6, by Sir George Foster, Minister of Trade and Commerce that he had effected arrangements with the British Government to place on exhibition at Toronto under the auspices of the Canadian National Exhibition next autumn an important industrial feature. Britain, the Minister said, had been exhibiting a large collection of goods of German and Austrian manufacture for the purpose of stimulating the production of such goods within the Empire. The exhibit would demonstrate the kind, quality, and cost of articles largely supplied by Germany before the war.

Sir George also asked the passing of an item of $150,000, to be used in carrying out his plan of trade extension previously outlined. There would be additional trade commissiosers, one in Petrograd; one in Omsk, Siberia; one in Italy, and two other sub-commissioners were being trained for service. A trade commission of six members would visit England, France, Belgium, and Italy. The commission would be accompanied by representatives of large interests.

The war had shown the need for trade research. The sources of research in Canada were both public and private. Universities, manufacturing enterprises, and private investigations were at work.

SHELL-MAKING AND ITS INITIATORS

THE proceedings of the Meredith-Duff Commission, covering the investigation of fuse contracts placed by the Canadian Shell Committee in the United States, are being followed with keen interest, and in no section of Canada's many-sided industrial life more so than by that of her metal-working institutions. What has already transpired indicates clearly that however much maligned the manufacturing members of the Shell Committee have been, or to what extraordinary extent imputation as to their self-interest has been pressed, no vestige of proof to warrant same has yet been forthcoming. As a matter of fact, we are constrained to believe that the investigation will not only have the effect of showing that these men have been patriotic above most, but will demonstrate our Captains of Industry to be head and shoulders above politicians and others of that ilk in straightforward dealing, and that it is a moot point whether in attending to their country's or its Empire interests they may not have made over much personal sacrifice. In one respect the latter is true, for taking into account the abuse heaped upon them during the past twelve months or so, this alone —which it unfortunately is not, were enough.

Canadian worth-while industrial enterprise is in process of being vindicated; there is nothing mushroom either about its roots or in its growth. We look to see a keener and more widespread appreciation of the rugged and substantial make-up of its directors as not the least gratifying outcome of the Meredith-Duff Commission Investigation.

LEADERSHIP A FACTOR IN INDUSTRIAL ORGANIZATION

SIGNIFICANT events have happened in recent months in industrial circles which indicate a peculiar restlessness in practically all of the various strata of society connected with manufacturing pursuits. Apart from any military aspect, and because only of the degree of perfection to which she has carried the organization of her national resources,—men, materials and money, Germany and her methods have been the subject of much comment and have elicited not a little admiration. Meantime, and no doubt largely as a result of the foregoing, earnest efforts are being made by the Allies in similar directions, which indicate that they, too, are fully alive to the necessity of at least equivalent organization, even if for nothing else than a means of insuring that future peace which is essential to the happiness and prosperity of all sane nations.

One feature stands out prominently in all criticisms of the present state of affairs,—the value of leadership in training the German people and developing such resources and ability as they possessed, so that they became in time of peace a vast commercial machine, the efficiency of which is well evidenced by the position they so quickly attained in the realm of commerce the world over.

In the present struggle of democracy against autocracy, the forces of the former have gradually but none the less surely grasped the fact that however much their principles are opposed to the latter, and however strenuously these may be displayed and practiced, efficient leadership is an essential factor. The latter is true in the success of any operation, military, civil or commercial. Efficient leadership, as such, however, has not been a conspicuous factor in the industrial life of Britain or the United States. Outstanding examples of commercial or scientific genius there have been, no doubt, but close intimacy between originators and applicators has not existed to the degree necessary to insure either of these countries deriving the fullest benefit from the latent potentiality of their man capacity.

The fullest and most sincere co-operation of all workers will be absolutely necessary in the ultimate struggle for commercial supremacy of the awakened nations, and in no branch of industry will this be so imperative as in engineering. Engineering is the one thing, next to, yet on a par at least with men on the fighting line, which is deciding this struggle, and will continue even more so to be the chief factor in the maintenance of position in the near future, or when peace again reigns.

Leadership, however, implies a following, and without loyal support by the great body of workers, the efforts of various bodies and individuals to insure a continuance of industrial prosperity will be largely, if not completely nullified. Given equal degrees of leadership, the influence of national traits is bound to modify ultimate results in different countries. Receptivity in regard to processes, methods and material has been a potent factor in the industrial rise of the United States, just as conservatism has to some extent been a characteristic of British workmen. It is just possible, however, that the distinctions in these respects may be less apparent in the future. Arising out of the manufacture of war supplies and munitions, American employers have been beset with labor troubles more or less serious, due to demands for higher wages and otherwise. On the other hand, the efforts of British and Canadian workmen, similarly engaged, have been greatly influenced by the fact that the safety and success of their fellow-countrymen on the firing line were directly dependent on their individual and collective attitude and exertions.

Conditions during the past year have done more than anything else to show the value of co-operation between managements and men. New methods, new tools, new men all have been requisitioned, adapted and absorbed in the widening circles of manufacturing activity, and, in so doing, have repeatedly demonstrated the necessity and value of leadership in securing successful accomplishment. Leadership and co-operation will be still more a requirement, as industrial conditions tend towards normal, and evidences are everywhere abundant in our midst that the most exacting demands will be met.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Monteal, Que., May 8, 1916.—General conditions throughout the industrial field remain unchanged. The apparent scarcity of labor, coupled with disputes over working conditions and wages, have resulted in a practical tie-up at certain points. A strike of carters in Montreal has caused the various railroads to place a temporary embargo on certain freight destined to that point. This, to some extent, is affecting the shipping at the harbor, as the opening of navigation places Montreal in a prominent position regarding marine transportation. Export trade is still seriously handicapped by the evident scarcity of ocean vessels, and under existing conditions little relief is expected, as the possibilities for additional tonnage seem very remote.

Pig Iron

The situation is practically unchanged. Owing to the apparent scarcity of furnace coke, and the abnormal demand, quotations are higher this week by 25c per ton on prompt, and 10c on futures; current prices being $2.25 and $2.50 for future.

Steel

Continued activity prevails throughout all branches of the steel and metal working industries, and plants are still working to capacity in an effort to meet requirements. The demand at present is light, and new orders have fallen off, which might indicate that buyers are holding back in the hope that prices may become easier. While the general run of material is holding firm at prices recently quoted, some lines have shown advances. Forging billets, Pittsburg, are up 50c, being quoted at $69 per ton. The demand for billets is still heavy, and producers of sheets are working at capacity and well supplied with bar stock. The Carnegie Steel Company are now quoting 1.475c per pound for heavy rails. This is in effect from May 1, and is an advance of about $4.50 per ton. Pittsburg price on iron bars is now 2.60c, being an advance of $2 a ton. Wire nails show a similar advance, present price being $2.50: fence wire and galvanized barb wire with advances of $4 and $2 respectively are now quoted at $2.45 and $2.35. The requirements of sheet consumers are very heavy, and in the case of automobile manufacture, the demand this year is greater than ever before. Effective May 1, an advance of $6 a ton is noted on wrought iron pipe up to 6 inches and an advance of $4 on the larger sizes. If the present heavy demand continues, further advances may be expected. Premiums are being offered for two or three months' delivery on boiler tubes, as nearly all the mills are booked ahead to the close of the year.

Metals

The general market conditions in all metals are very quiet. Foreign demand for copper may follow recent inquiry, and increased activity is looked for. Uncertainty of supply and delivery is creating a very unsteady tin situation, and prices are subject to change. Spelter has shown signs of weakness during the past week or so, owing to the situation prevailing in U. S. Government circles. The market in lead is becoming easier, as many of the large consumers are well covered, and the general demand is light.

Copper.—The present market is comparatively quiet, with possibilities of future activity, due to extensive inquiries from foreign sources for this year's delivery. With both market and production in their present state, the chief difficulty with a heavy additional demand will be the supply of metal. Unless the future demand is of an extraordinary nature, it is generally expected that the situation can be taken care of, but slightly higher prices may be expected. London copper is very strong on advancing prices; electrolytic being quoted at £150; standard firm at £137, and £130 for spot and futures respectively. New York quotations are also slightly higher; 30c being asked for lake, 31c for electro, and 28c for castings. Local dealers report a strong and active market, with prices firm and unchanged.

Tin.—Difficulty is being experienced by dealers in securing metal, owing to the delay in securing shipping permits from London. The situation is becoming quite serious, and some importers are un-

able to make delivery on placed orders, being forced to buy available metal to satisfy customers. A fair volume of business was reported for the week, with prices fluctuating under an irregular market. Heavy demand at the early part of the week resulted in a sharp advance, but the easing off during the later half caused a decline of 2c on the New York market, the present quotation being firm at 50½c. Quotations are relatively firm. London reports slight increases on standard and straits spot, quotations being £201 for each. Local conditions are unchanged, with prices firm at 50c per pound.

Spelter.—The market is very quiet and prices are weakening. Recently published reports on the spelter situation, showing the prospective increase in production, have had much to do with the present state of the market. Slight activity is noted in recent inquiries from galvanizers, for second quarter metal, but the general tone is one of comparative dullness. Present London prices are £98 for spot and £92 for futures. New York shows a decline of ¾c on the week, present quotation being 17½c nominal. Local dealers report a quiet market, with prices weakening, present price of 22c showing a decline of 1c over last week.

Lead.—Prices are holding comparatively firm, as little evidence is noted of heavy selling. Trust and outside prices are almost on a par, at 7½c New York, with some outside interests quoting ⅛c lower. In response to a dull market, local dealers have lowered prices, this week's quotation of 9¾c showing a decline of ¼c per pound.

Antimony.—Little interest is shown in antimony at present. The market is quiet; quotations hold firm, and very little change is anticipated in view of the fact that the current output is well absorbed. Conditions here are unchanged, with prices firm at 45c.

Aluminum. — Unchanged conditions prevail and prices are firm at 68c per pound.

Machine Tools and Supplies

The general machinery situation is becoming easier each week, as the requirements of machines for munition purposes are almost taken care of, and the delivery of long-placed orders are more reliable. Tool builders are, however, kept busy on the heavier types of machines, and those for domestic requirements, which, under existing conditions, are very encouraging. If strikes in the States are extended it may affect the present machine tool situation as well as other lines of metal industries. Recent advances to employees in many industrial plants, coupled with the high cost of raw and semi-finished material, are resulting in increased prices on many lines of machine shop supplies. The demand is still as great as ever, and in some instances full delivery of requirements is impossible.

Old Materials

Consumption of old materials at present is very great, but many of the large users are well supplied for immediate and early future requirements. Belief is prevalent that prices will become easier. Wrought iron scrap is in good demand. Local dealers report fair business, with prices firm and unchanged.

Toronto, Ont., May 9, 1916. — Business conditions continue to show steady improvement and the favorable outlook is helping to maintain a spirit of confidence throughout the country. Orders or war equipment and supplies are keeping the factories busy, many working at full capacity. The shortage of much raw material is becoming more serious and is causing considerable concern to manufacturers while the difficulty that is being experienced in securing sufficient help is also tending to restrict production. The freight situation while not quite so acute is still causing considerable inconvenience to merchants especially as regards goods consigned to Eastern points. Shipments from United States are also being delayed owing to congestion in the railway yards. The customs returns for the port of Toronto for April indicate a marked revival in trade. The revenue for April was $2,767,301, being a gain of $1,264,000 over the corresponding month of last year. The receipts constitute a record for the port.

Steel Market

While prices of steel products are not advancing quite so rapidly as they have been doing, the market is just as strong and the mills are booking orders well into the first quarter of 1917. Deliveries are getting more backward as the steel companies cannot take care of all the business offering. The Algoma Steel Corporation have booked an order for 15,000 tons of rails from the Pere Marquette Railway. Prices are being well maintained, there having been few important changes made during the week. Smooth steel wire No. 0-9 gauge has advanced 15c and is now quoted at $3.90 per 100 lbs., base. Cold rolled shafting is very firm at last week's advance. The demand for shafting continues heavy and prices have a higher tendency. Prices of boiler plates are unchanged but the market is very firm. Some makers of boiler tubes state that they are practically sold out for the remainder of the year, while on seamless tubes they are sold up for the first quarter of 1917. Prices are very firm and are likely to be higher in the near future.

The galvanized sheet situation is unchanged, the market being firm and prices well maintained. The spelter situation shows no improvement and galvanizing plants are still operating at considerably reduced capacity. The demand for black and blue annealed sheets continues heavy and shipments are becoming more backward than ever. The market is firm and prices unchanged.

The steel market in the United States continues very firm and prices are still advancing. The mills claim that they are trying to hold prices in check but without success, and that consumers are putting the market up by bidding high prices for material which the mills cannot furnish for six to eight months. Steel bars are unchanged at 3c, and iron bars are higher at 2.60c, Pittsburgh. Plates and shapes are unchanged at 3.75c, and 2.60c, Pittsburgh. Forging billets have advanced again and are now quoted at $69 per ton Pittsburgh. The ferro-manganese market is a little easier but very high prices are still being paid for prompt delivery ferro.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attaché, Room 904 Flat Iron Building, New York City.

Scrap Material

Conditions in the markets are practically unchanged and prices have been maintained at last week's level. The general tendency for prices continues upward and the market is very firm at unchanged prices. The only exception of any importance is zinc which has declined and is now being quoted at 14c per lb. Although the pig lead market is weaker, prices of scrap lead are unchanged. All copper and brass prices are very firm with demand fairly active. Heavy melting steel is unchanged but firm on good demand.

Machine Tools

There is little change to note in the situation. Business is quieter but there is a steady demand for tools principally in single units for shell plants and equipment for tool rooms.

Supplies

Prices generally for machine shop supplies continue to advance although some lines have declined. A new bolt discount has been issued, making an advance of about 15 per cent. The new discounts are as follows: coach and lag screws, 50 per cent.; machine bolts 3/8 in., and less 40 per cent.; machine bolts 7-16 in., and over 30 per cent.; blank bolts and bolt ends 30 per cent., and stove bolts 62½ per cent. The linseed oil market is weaker and prices have again dropped, the new quotations being 93c for raw, and 96c for boiled oil, per gallon. Turpentine has also declined and is now quoted at 72c per Imperial gallon. Manila rope has advanced 1½c. and is now quoted at 22½c per lb.. base.

Metal Markets

With the exception of copper there is a decidedly easier tone to the markets, and lower prices have been registered for tin, spelter and lead. Lead is particularly dull, the outside market being now lower than the "Trust" price. The copper market although quiet is strong on account of the exceptionally heavy demand. Tin is firm in London but weaker in New York, the difficulty in getting licenses still dominating the market. The spelter market is apparently being affected by the strained relations between the United States and Germany. Antimony and aluminum are quiet and unchanged. Solders have declined slightly following the weakness in the tin and lead markets.

Copper.—Although the market is quiet, copper prices are tending still higher as a result of a persistent and widespread demand which is fast cleaning up all available supplies, other than for delivery in the last three months of the year. It is reported that the British and French Governments are in the market for another large amount of copper for delivery during the first quarter of 1917. The local market is strong and quotations nominal at 32c per pound.

Tin.—The market is weaker and lower for spot tin but firm for futures. The market in New York is being affected by the difficulty still being experienced in obtaining licenses to ship tin from England. Local quotations have declined 2c and are nominal at 54c per pound.

Spelter.—The primary market is dull and easy being depressed by the strained relations between the United States and Germany. Dealers are doing nothing and are apparently waiting developments. Spelter has declined 1c locally and is now quoted at 21c per pound.

Lead.—The market is very dull and little business offering. The outside market is now lower than the "Trust" price of 7.50c New York, the latter being unchanged. The demand is light and situation featureless. Lead has declined ½c and is now quoted locally at 9½c per pound.

Antimony.—The situation in the antimony market has a tendency to depress prices but meanwhile quotations are unchanged and nominal at 47c per pound.

Aluminum.—The market is dull and featureless with quotations unchanged at 68c per pound.

Solders. — Prices are slightly lower due to the decline in lead and tin. Guaranteed is now quoted at 31c, and strictly at 29c per pound.

LOGGING MACHINERY FOR BURMAH

In a communication to the Departmest of Trade and Commerce, H. R. MacMillan, Special Trade Commissioner, states that an opening exists in Burmah for Canadian machinery used in logging operations. Authority has just been granted by the Government for the purchase of one logging engine, to haul logs up to a maximum of 3 tons weight, a distance of 3,000 feet over smooth ground, and although previous machines have been of American construction, a Canadian machine would now be preferred. If this order were satisfactorily executed, it is stated that further business could undoubtedly be secured as forest development is only in its initial stages in Burmah. Canadian manufacturers should communicate immediately with the Conservator of Forests (whose name and address will be supplied on application to the Department. Refer File No. A-2017) and forward catalogues, price lists, and complete description of types of engines.

CHEMICAL PRICES SHOW BIG ADVANCE

ADVICES from New York state that prices of chemicals used in the manufacture of war materials have receded somewhat from the high levels recorded in the later months of 1915. This has been due partly to increased production and to the fact that most of the large buyers placed their contracts ahead last year, both these tending to lessen the pressure of demand.

The decline has been comparatively small on the whole, one or two chemicals having been affected but little, while the whole list of the products in question are now at levels considerably above the normal and the tone of the market is healthy. In some instances quoted prices are more or less nominal, as trade authorities say a buyer wanting a large quantity would hardly be able to get it at the present quotations because of the sold-up condition of sellers.

Below is a list of the principal chemicals used in making explosives, with the market price as of July 1, 1914, the high price reached in 1915 and the existing market level:

	1914 July 1	1915 High	1916 May 3
Sulphuric acid (lb.)	1c	3¾c	2½ to 3c
Benzol (gallon)	$0.25	$1.25	$0.80
Toluol (gallon)	1.00	5.00	4.35
Carbolic acid (lb.)	.07	1.75	.90
Picric acid (lb.)	.40	1.75	1.60
Nitric acid (lb.)	.04	.07	.07

GOVERNMENT AIDS RAILWAYS

THE Dominion Government's aid to the Canadian Northern Railway and Grand Trunk Pacific Railway appears in the supplementary estimates presented to the House on May 2. There is provided a loan of $15,000,000 to the C.N.R., and $8,000,000 to the G. T. P. An item of $150,000 is also provided for inquiry and report upon the railway situation of Canada, and another of $10,000 for an audit of the revenues and the expenditures of the G. T. P. and C. N. R.

The loan to the C. N. R. is chargeable to income and is at six per cent., payable half yearly, and is to be used for expenditure made or to meet indebtedness incurred in paying interest upon securities of other companies in the C. N. R. system and upon construction. It is to be secured by mortgage, and so much of said loan as may be applied for the benefit of any company included in the C. N. R. system is to be secured in addition by mortgage on the undertaking of such company.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Renfrew, Ont.—The Renfrew Machinery Co., will rebuild their plant which was recently destroyed by fire.

Toronto, Ont.—The Imperial Oil Co., propose purchasing a site covering 11 acres for the purpose of erecting an oil refining plant near Ashbridge's Bay.

Vancouver, B.C.—Thomas Shaw, Victoria, B.C., will establish a boiler shop in Vancouver, B.C., and is in the market for a 15 h.p. motor, air compressor, etc.

Quebec, Que.—Part of the General Car & Machinery Co. plant at Montmagny, near here, was destroyed by fire on May 7. Charles A. Paquet is general manager.

Renfrew, Ont.—The dry house of the O'Brien Munitions was completely destroyed by fire on May 5. The damage is estimated at $40,000, and is covered by insurance.

Montreal, Que.—William Hood & Son, 10 Richmond Square, are in the market for a trimming press or punch for drop forgings; also a power hammer, belt or steam-driven.

Brantford, Ont.—William P. Kellet, former general manager of the Lake Erie & Northern Railway, who has been running a munition factory in the Ker & Goodwin plant here, has sold out his interest to Ker & Goodwin, and has gone to Toronto.

London, Ont.—The School Board will install a boiler at the new technical school and will be in the market for iron and wood-working machinery, electrical equipment, etc.

Montrose, Ont.—The Michigan Central Railway Co. has let the contract for the construction of a roundhouse, coal dock and other buildings at Montrose, Ont., to Wallbridge & Aldinger, Detroit, Mich. The buildings will be of brick and concrete and will cost $250,000.

St. John, N.B.—The T. McAvity & Sons, recently received an order for munitions and will build an iron and brass foundry on Marsh Road adjacent to the Intercolonial Railway tracks. It will be one of the largest in the lower provinces. The company will spend $100,000 on the plant the first year and is in the market for the following machinery: Lathes for making 8-in. shells, from 16 to 18 in. single-purpose, and from 24 to 35 in. standard lathes for roughing, finishing and boring, etc.; 36 to 40 drilling machines, banding presses, wave ribbing, tapping, recessing and copper band turning, thread milling machines with complete equipment; also an entire tool-room equipment; machinery for power plant, including a 250 x 500 k.w. generator unit, either direct or alternating current; a compound condensing engine, high-speed preferred; eight 25 or 30 k.w. motors, etc.

Electrical

Ingersoll, Ont.—The town council contemplate the installation of an ornamental lighting system.

Toronto, Ont.—The Toronto Hydro Electric Commissioners propose building an addition to the transformer station at Front and Cherry streets. Approximate cost $6,000.

Niagara-on-the-Lake, Ont.—The town council propose installing motor-driven pumps in connection with the water works system.

Cobalt, Ont.—The Northern Ontario Light & Power Co., has signed the franchise recently drawn up, and will proceed at once with changing the lighting system on the streets.

Toronto, Ont.—The Toronto Hydro-Electric Commission have decided to extend the West Toronto sub-station at Edwin and Ruskin avenues. The contract for this has been awarded to A. J. Penberthy. A new sub-station is to be erected at 101 and 103 Jefferson avenue, the land purchased to cost $5,950.

ELECTRICAL EQUIPMENT FOR NEW ZEALAND

The Department of Trade and Commerce has been informed by W. A. Beddoe, Trade Commissioner, Auckland, that the Oamaru Borough Council invites tenders up to June 23 for the following contracts:—Overhead mains; power station equipment (Pelton wheels, alternators, etc.); service metres and transformers. Plans and specifications have been sent to the Department, where they may be secured on application. (Refer File No. A-1939.)

Municipal

Wyoming, Ont.—The Hydro by-law was unanimously carried here recently.

Rodney, Ont.—The Hydro by-law was carried here on May 1 by a majority of twenty-six.

Arthur, Ont.—The Hydro-Electric by-law, voted on here last Monday, was carried by a vote of 211 to 6.

Clinton, Ont.—The Town Council contemplates an expenditure of $15,000 for extending the water works system.

Cartierville, Que.—The sum of $23,000 has been voted by the Town Council to complete the Imhoff tank for the purification of sewage. The original estimate of cost was $10,000.

Port Hope, Ont.—The by-law to grant exemption to a new manufacturing industry was carried by a large majority on Monday. There were 356 votes cast, and only five were recorded against the by-law. S. E. Brandon, of Toronto, is head of the new concern, but is not decided yet what line of goods the company will manufacture.

Toronto, Ont.—At a meeting of the city council recently by-laws were passed authorizing the issue of debentures to raise approximately $3,500,000 to cover the cost of local improvement works carried out in 1914-15. In addition, other money to provide for the issue of instalment bonds for work already authorized and completed; also to provide $1,248,000 for extension of the Civic Hydro System.

General Industrial

Sandwich, Ont.—The Canadian Salt Co., are building an extension to their plant here.

Toronto, Ont.—The Campbell Flour Mills Co., will build a cooperage plant to cost $5,000.

Winnipeg, Man.—The Dominion Government propose erecting a terminal elevator here at a cost of $500,000.

Peterborough, Ont.—The Quaker Oats Co., will build an extension to their factory here at a cost of about $50,000.

Toronto, Ont.—Fire recently caused $7,500 damage to the plant of Wilson & Warden, 58 Duchess street, manufacturers of bottlers' supplies, etc.

Montreal, Que.—The St. Lawrence Paper Co., of this city will build a paper mill at Cap Madeleine, Que.

St. John, N.B.—It is proposed to rebuild the government elevator here which was burnt down about two years ago. The cost is estimated at $500,000.

Toronto, Ont.—Work has started on the erection of a factory for the Flint Varnish & Color Co. Estimated cost, $150,000.

Simcoe, Ont.—The Unique Shoe Co. propose to build a factory at an approximate cost of $10,000. A by-law will be submitted to the ratepayers.

Harrow, Ont.—The W. Clark Co., Montreal, propose building a cannery here. R. Findlay Montreal, is the architect, and the approximate cost is $15,000.

Winnipeg, Man.—The Stovel Co., printing and engraving plant was destroyed by fire on May 2. The loss is estimated at $400,000, with insurance of $266,000.

Chatham, Ont.—Machinery is being installed at the Chatham Shoe Co. plant, and it is expected that manufacturing will begin shortly. E. S. Hunt is president of the company.

Berlin, Ont.—The large frame building, known as the Old Skating Rink, was totally destroyed by fire on May 6. The building was occupied by the Schreiter Bedding & Mattress Co. and Walters & Sons, manufacturers of fibre products, both of whom suffered a total loss on their stock. The loss is estimated at about $15,000.

Tenders

Burlington, Ont.—Tenders will be received up to May 13, 1916, for a two-ton combination chemical engine hose truck. Specifications on application. Jas. S. Allen, clerk.

Charlottetown, P.E.I.—Tenders will be received by the engineers, R. S. & W. S. Lea, Montreal, until May 20, for the erection of a pumping station and installation of a one-million-gallon pump at Charlottetown.

Haileybury, Ont.—Tenders will be received up to May 15, 1916, for the furnishing material and erection of Haileybury School of Mines Building. Plans and specifications may be seen at the secretary's office, T. & N. O. Ry. Station.

North Bay, Ont.—Tenders will be received up to May 15, 1916, for the supply and delivery of approximately 3,100 feet of 6-inch and 630 feet of 4-inch cast iron pipe and specials. Specifications may be obtained from H. J. McAuslan, town engineer.

London, Ont.—Tenders will be received until May 12, 1916, for the construction of the East End Sewage Disposal Works. Specifications, forms of tender, plans, etc., may be seen at the City Hall, London, or at the office of the engineers, Chipman & Power, 204 Mail Bldg., Toronto.

Hamilton, Ont.—Tenders addressed to the Chairman Board of Control, will be received up to May 16 for the supply and installation of a gasoline tank pump and oil cabinet for City Garage, Hughson Street. Specifications may be obtained from S. H. Kent, city clerk, at the City Hall.

SAW-MILL MACHINERY REQUIRED IN RUSSIA

Makers of saw-mill machinery will learn with interest that Russia now occupies first place among the nations of the world in the extent of its timber resources. The total area of the Empire is about one-seventh of the land surface of the globe, and 39 per cent. if it is under forests.. Those in European Russia cover an area of 474,000,000 acres; in Finland, 50,500,000 acres; in Poland, 6,700,000 acres; and in Caucasus 18,600,000 acres; a total of 549,800,000 acres, exclusive of Siberia. The Russian Forestry Department places the total timber land in Siberia at 810,000,000 acres, of which two-thirds can be successfully placed on the market.

Ottawa, Ont.—Tenders addressed to the chairman of the Board of Control will be received up to May 16, 1916, for the superstructure for Pretoria avenue bridge. Plans, specifications and full particulars may be obtained on application to the city engineer's office on a deposit of $50. F. C. Askwith, acting city engineer.

Prince George, B.C.—Tenders for (a) wire bound wood pipe; (b) lap-welded steel pipe; (c) specials or castings; (d) valves, and (e) hydrants, will be received up to May 10, 1916. Plans and specifications may be obtained at the office of J. A. Turner, city clerk, Prince George, or the consulting engineers, DuCane, Dutcher & Co., Vancouver, B.C.

Toronto, Ont.—Tenders will be received addressed to the chairman, Board of Control, City Hall, up to May 23, 1916, for the complete construction of a steel frame, brick-faced tile addition, including heating plant, to the St. Clair avenue car barn, Christie street. Specifications and forms of tender may be obtained upon application at Room No. 311, Department of Works, City Hall.

Ottawa, Ont.—Tenders for submarine cable will be received until May 15, 1916, for 10 knots of single conductor submarine telegraph cable (107 lbs, copper and 150 lbs. gutta percha per knot), with sheathing of 12 No. S.S.W.G. iron wires, to be delivered at Halifax, N.S. Specification and forms of tender can be obtained on application to the office of the general superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received by the Chairman Board of Control, City Hall, up to May 23, 1916, for the supply and delivery of: One single truck, double end, street car, completely equipped; one car body, double end, single truck; equipment for one single truck car, electrical equipment; equipment for one single truck car. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Trade Gossip

The Manitoba Rolling Mills new plant at Selkirk, Man., commenced operations last week.

Ottawa, Ont.—The estimates of the Public Works Department include an appropriation of $600,000 for improvements to Toronto harbor.

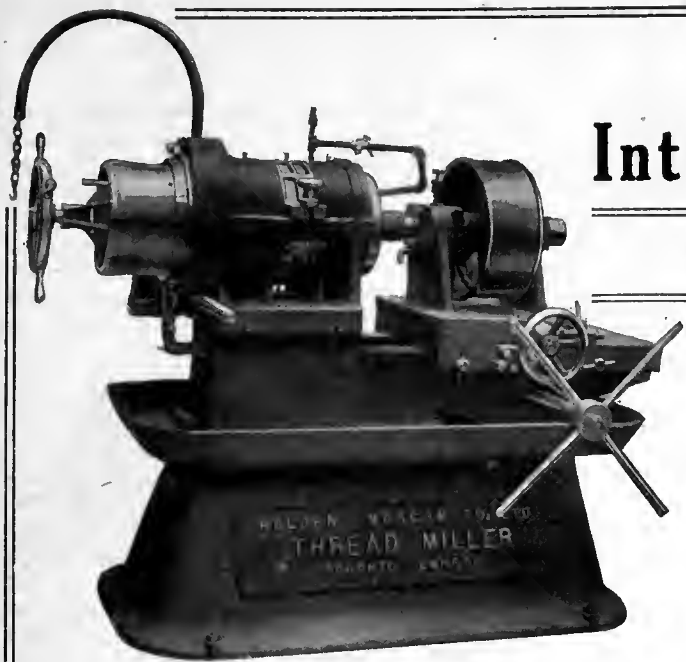
Toronto, Ont.—The Ontario Government has passed an Order in Council transferring the control and operation of the Trent Valley power undertaking to the Provincial Hydro-Electric Commission.

The Hudson Motor Car Co., whose incorporation is in Michigan, has been given permission to carry on its business of manufacturing and dealing in automobiles to the extent of $40,000 a year, in the Province of Ontario.

Ottawa, Ont.—Sir Thomas White's bill providing for the payment of a bounty on zinc produced in Canada has passed, and also a subsidy for the Quebec and St. John Valley Railway. The bill provides for Government operation of the road.

Toronto, Ont.—It has been decided to recommend to the Board of Control that a public and industrial bureau be formed, consisting of representatives of the several organizations, such as the Board of Trade, Manufacturers' Association and kindred bodies.

Cobalt, Ont.—The Dominion Rand Co., which is operating a copper mine near the T. & N. O. at Temagami, shipped another car of ore last week, which weigh-



The Holden-Morgan
Internal Thread Millers

Representing 7 in., 8 in. and 9 in. sizes.

The machine illustrated above has for its principle simplicity and perfection, and was designed especially for milling the internal threads on the nose or base of the shell body.

The shell is carried between two conical surfaces in the interior of the mandrel, this ensures the thread being milled perfectly true with the axis of the shell, and holds the shell in a much firmer and truer position than is possible with collet chucks. The master screw is chased on the outside of the mandrel, which entirely precludes the possibility of "drunken threads."

The milling head is carried in movable carriage and both slides are moved up to positive stops and locked so that thread is milled absolutely the same size in every instance.

Each machine is complete with oil-pump and pan.

NOTE—Countershaft is provided with machines over 6 in. size only, as smaller sizes are run direct from line shaft.

Don't Depend on Somebody Else

For Your Small Threaded Parts

THREAD THEM YOURSELF

A GEOMETRIC THREADING MACHINE SOON PAYS FOR ITSELF

Takes floor space 2 ft. x 3 ft. and is complete with countershaft, change speed gear, adjustable stop for gauging length of thread.

No rough threads with the Geometric. They are as true and clean as can be produced on any Screw Machine.

From 1/8-inch pipe thread to 1-inch diameter is the usual range of the machine, but where fine pitch threads are to be cut on larger diameters, it can be fitted with a Die Head that will take care of the work.

Submit Your Threading Proposition to Us.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN, CONN., U.S.A.

Canadian Agents: Williams & Wilson, Ltd., Montreal; The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, and St. John, N.B.

ed 68,920 pounds recently, and as soon as the breakup is over the company expect to ship one or two cars daily.

Toronto, Ont.—The Provincial Hydro-Electric Commission is to enter into a general agreement with York township for the supply of electric energy to be delivered by the Toronto Hydro system, which is now supplying certain sections of the township with light and power.

A Canadian Research Bureau has been established by the C. P. R. Its purpose is to investigate and study the natural resources of the country in a scientific manner. Research laboratories will be established at different points in the Dominion. Arthur D. Little will have charge of the bureau.

Hudson Bay Railway.—Estimates of the Department of Railways include appropriations of $3,000,000 to carry on the construction of the Hudson Bay Railway and its terminals at Port Nelson, and $1,500,000 for work on the National Transcontinental Railway. Hon. J. D. Reid estimates that the project will cost in all $26,000,000, and will be completed in the autumn of 1917.

The Collingwood Shipbuilding Company successfully launched on April 29, the second of the oil tank steamers which they are building for the Imperial Oil Co. The christening ceremony was performed by Miss Frances Mayer, daughter of the vice-president of the latter. The Imperial Oil Co. has awarded the Collingwood Shipbuilding Co. three contracts for vessels of this class, and also an order for two larger ocean-going steamers, making five vessels in all.

Medicine Hat, Alta.—A deal was recently completed whereby the Western Canadian Steel Co. takes over the Redcliffe Rolling Mills plant. The purchaser is the Giant Corporation, which is about to erect a smelter just west of Medicine Hat. Individual members control the Western Canada Foundry Supply Co., which recently merged a large number of western industries. One of the men interested in this concern is Mr. McLaws, barrister, of Lougheed, Bennett & McLaws, Calgary.

Victoria, B.C. — The Government measure for assistance to shipping will be introduced shortly in the House. The bill contemplates, it is reported, the formation of a commission which will be given power to float bonds to the amount of two million dollars and from the proceeds to lend sums on ships to be built in the province for ocean-going trade up to 55 per cent. of their value. Restrictions will be placed, it is said, so as to provide that the boats must do business in and out of British Columbia ports. When the aggregate of two millions has been reached further legislative sanction will be required before any more money can be loaned.

Newfoundland Seal Catch.—The sealing season which closed on April 30 was one of the most successful in years, according to reports received at Curling, Nfld. Notwithstanding the loss from the fleet of all but one of the steel steamers through purchase or impression for Admiralty service, the catch reached a total of 225,000 pelts. The total value is estimated at $750,000. Nine of the twelve steamers which took part in the hunt have returned to port, and the others are expected to arrive within a day or two.

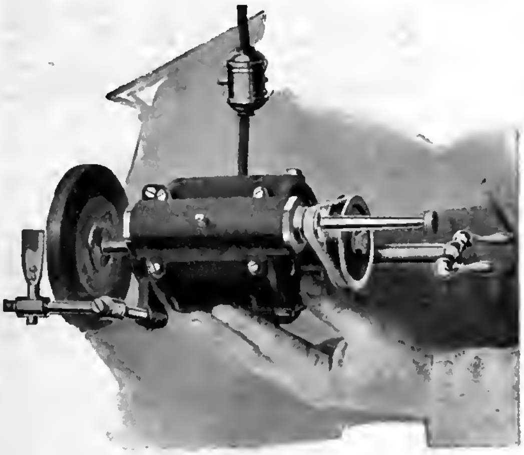
Railway Investigation.—The commission which is to be appointed by the Government to investigate and report upon the railway situation of Canada with a view to the nationalization of two at least of the present transcontinental lines will be announced shortly, and the investigation will begin in the near future. It is understood that one of the commissioners to be named will be a gentleman occupying a very prominent position in the railway world of the United States, another being a British or Canadian railway expert of equal eminence. These two commissioners, it is expected, will be given authority to select a third member.

New Ferromanganese Process.—It is reported from Pittsburgh, Pa., that a process for extracting ferro alloys of manganese and silica from slag, which it is claimed will result in an immense saving to steel manufacturers, has been discovered by George A. Hays, of Sewickley, Pa., and George D. Lain, of Elmira, N.Y., students at the Carnegie Institute of Technology. Ferro manganese and silica are essential elements in the manufacture of steel, but since the start of the European war both have greatly advanced in price, the former from $75 to $400 a ton. As a result of the process, slag which has always been practically a waste product will now become of commercial value.

The Turbine Equipment Co., Toronto, Ont., have sold to the Nova Scotia Steel & Coal Co. a 1,000 h.p. De Laval marine type steam turbine, complete with double helical reduction gears, for installing in a new boat which is being built by the Steel Company. The company will also supply the condensing equipment, bilge and boiler feed pumps.

Victoria, B.C.—The establishment at Ocean Falls, B.C., by the Fleishacker & Johnson interests of California of a $2,500,000 paper mill as an addition to the pulp mill already operating there is announced by Louis Bloch, of San Francisco, Cal., vice-president and general manager of the Crown Willamette Paper Co. The company Mr. Bloch represents

Aikenhead's DUMORE GRINDER



The DUMORE Portable Grinder. The only small grinder giving wheels the correct surface speed. Speed, 30,000 R. P. M.

IF you put a DUMORE Portable Grinder to work in your shop, you will quickly see a notable shrinkage in your grinding costs.

WHY?

It is portable—weighs but 17 pounds—easily carried from one job to another.

The DUMORE will do more and better work than the ordinary grinder. It saves time — and time means money.

A rapid, practical way of grinding special milling cutters.

Wahlstrom Tool Company

350 Carroll Street Brooklyn, N.Y.

is one of a number operated by the California interests. The property on which the pulp mill is situated and which will be the site of the new paper mill, consists of more than 60,000 acres of timber, most of which is excellently adapted for pulp paper purposes and a sawmill capable of cutting 400,000 feet of lumber a day. Archie Martin is general manager of the Ocean Falls plant.

Personal

H. D. Cameron has been appointed mechanical engineer of the C. N. R., with office at Toronto, Ont.

Albert C. Smith, president of the Smith Foundry Co., Fredericton, N.B., died recently.

C. E. Raup, manager of S. J. Shimer & Sons, Galt, Ont., has resigned and has left Galt, to assume an important position with the company at their headquarters, Milton, Pa. S. J. Shimer & Sons recently disposed of their Canadian branch at Galt to a local syndicate.

Allan Purvis, superintendent of the C. P. R. at London, Ont., has been appointed general superintendent of the Eastern Division in place of A. E. Stevens, who has been transferred to a similar position at Moose Jaw, replacing J. G. Taylor, who had to relinquish his duties on account of ill-health.

W. Grant Fraser, of New Glasgow, N.S., has been appointed under the Imperial Munitions Board, as chief inspector of all munition factories in the Maritime Provinces. Mr. Fraser has had a long experience in steel manufacture, having been one of the smelter foremen for the Nova Scotia Steel & Coal Co., both at New Glasgow and at Sydney Mines.

Building Notes

Ottawa, Ont.—The estimates include an appropriation of $1,500,000 for the restoration of the Parliament Buildings here.

Toronto, Ont.—The city architect has issued a building permit to the Separate School Board for additions to the St. Joseph's School on Leslie Street, at a cost of $6,000.

Winnipeg, Man.—The new Bank of Hamilton building for which tenders will be called in two weeks and on which work will commence shortly will cost about $500,000. J. D. Atchison, of Winnipeg, is the architect.

Toronto, Ont.—The Toronto Harbor Commission at a special meeting held on May 5, decided to grant a 21-year lease

Page 58
Contains some interesting Reading.

of Bayside Park to the T. Eaton Co., for a site for their proposed million-dollar mail order building.

Winnipeg, Man.—The Carter-Halls-Aldinger Co., of Winnipeg, have been awarded the contract for the extension to the Winnipeg Grain Exchange. Three more storeys are to be added to the building at a cost of $200,000. Work will be started at once. Messrs. Owen & Jordan are the architects.

Hamilton, Ont.—The Technical Committee of the Board of Education has decided not to begin the construction of the new Technical School until 1917. The site will embrace the property on Wentworth street known as Brown's nursery, and part of Britannia Park, the entire cost being about $75,000.

Toronto, Ont.—The Separate School Board have awarded the following contracts for St. Monica's school: McGregor & McIntyre, structural steel, $1,134; W. J. McGuire, plumbing, $2,945; P. E. Regan, heating, $3,125; Canada Electric, wiring, $197. For St. Peter's school: Reid & Brown, structural steel, $735; W. J. McGuire, plumbing, $895; D. Millar, heating, $200; Canada Electric, wiring, $87.

Trade Gossip

Nickel Refinery Plan.—When the International Nickel Co. plan for a refinery in Canada was first discussed it was understood that the company proposed to build on the Atlantic seaboard. Recently there has been talk of a refinery in Ontario, and New York reports state that two sites are under consideration—one at Toronto, and the other at Hamilton—and when a decision is made between the two, work will go ahead on a $1,000,000 plant. The obvious economies which would be offered by a refinery situated on the seaboard naturally make reasons for the change—if it is a change and not an extension of the original plan—rather obscure.

Stresses in Boiler Heads.—The Babcock & Wilcox Co., of Bayonne, New Jersey, through its representative, Isaac Harter, general superintendent, has presented to the Department of Mechanical Engineering of the University of Illinois, a 42-inch cylindrical drum to be used in an investigation which has been undertaken by the Engineering Experiment Station to determine the stresses in convex boiler heads. One head is provided with a manhole, and the other, the head to be tested, is fastened to the shell by specially designed tapered bolts to facilitate its removal and replacement by heads of different design. The shell of the drum is made unusually heavy to permit pressures to be carried above those normally used in practice.

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

SITUATIONS VACANT

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month. Box 184, Canadian Machinery.

WANTED — MACHINISTS AND FLOOR hands on heavy and miscellaneous medium work; steady employment, modern shop, good wages. Apply, stating age and experience, P.O. Box 6, Walkerville, Ontario. (6)

WANTED — TWO FIRST-CLASS STEEL moulders. Apply Nova Scotia Steel & Coal Company, Limited, Sydney Mines, N.S. (15)

WANTED—OUTSIDE MACHINIST TO ACT as mechanical foreman on construction work. Apply to A. B., Canadian Machinery. (15)

WANTED — YOUNG CHEMIST WHO HAS had some experience in analysis of iron, steel and other steel plant products. Apply to X. Y., Canadian Machinery. (15)

WANTED—FIRST-CLASS BOILER MAN TO take charge of battery of water tube boilers, 1200 H.P., which will be increased. Should be familiar with steam engine and air compressor. Reply, giving particulars of experience and salary expected, Box 191, Canadian Machinery. (19)

WANTED

WANTED BERTRAM WAVING ATTACHment for 4.5 Shells, with or without Lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson Limited. (R.T.F.)

WANTED—HYDRAULIC PUMP, GOOD FOR 2,000 lbs. pressure capacity for 16" diameter cylinder press; belt-driven preferred. Canadian Consolidated Felt Co., Ltd., Berlin, Canada. (18)

ENGINEER WANTS AGENCIES FOR MONTreal and district. Side line or specialties, on commission basis. X.Y.Z., Canadian Machinery, Montreal. (19)

WANTED — BERTRAM WAVING ATTACHment for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

BOILERS WANTED—TWO SECOND-HAND, about 150 H.P.; at least 80 pounds working pressure under Ontario Government Boiler Regulations. Give full particulars, Box 198, Canadian Machinery. (19)

FOREMAN WANTED WITH ABILITY and experience to take charge of plant making large size shells. Strictly modern factory with new machinery. Applicants only considered who are holding positions of responsibility and can give satisfactory references. State salary. Correspondence strictly confidential. Apply to Box 195, Canadian Machinery.

TOOL DESIGNER WANTED—TO DEsign a complete set of tools for machining 8" and 9.2" shells. Preference will be given to applicants who have actually had experience on shell work. New equipment throughout. Steady position and good salary. Correspondence confidential. Apply to Box 196, Canadian Machinery.

SUPERINTENDENT WANTED TO take charge of production in a new factory making large shells. Applicants must qualify by having proven their ability to carry out a large undertaking successfully. Salary according to ability. Correspondence confidential. Apply to Box 197, Canadian Machinery.

20 pieces pp. 429. 70

INDEX TO ADVERTISERS

Machining and Assembling the Military Rifle Bayonet-II.

By F. H. Mayoh

Bayonet manufacture, like that of shells, has been both war-initiated and war-stimulated, although as far as we are concerned the latter has demanded and monopolized the full extent of our metal-working plant activities. Bayonet production, it will be noted, is quite distinct in its operation features from that of shells; as a result our readers will find in the accompanying articles a welcome diversion, besides obtaining at the same time a further insight into the manufacture of another and highly important piece of the individual soldier's equipment, offensive as well as defensive, and particularly effective in either case.

HAVING previously described the making of the bayonet blade, reference is made to Fig. 12 for details of hilt and guard crossing which are made from forgings.

The hilt of a bayonet is so made that it provides a good means of gripping

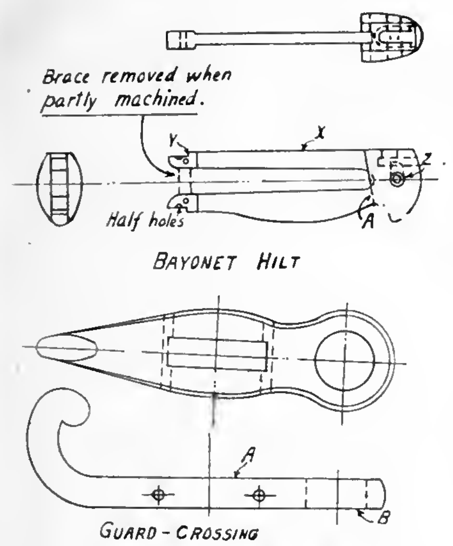

FIG. 12—DETAILS OF TWO IMPORTANT BAYONET PARTS

when used in the hand as well as being adapted for quick attachment to the rifle.

The guard crossing is made to provide some protection to the user of the bayonet and is part of the means for attaching the bayonet to the rifle.

As the hilt forging comes from the dies it has a brace across the open end as shown by the dot and dash lines. This brace is cut away after part of the machining is done.

The first operation on the hilt is to finish the back edge X, Fig. 12, and this is accomplished by disc grinding. This provides a starting point from which the other operations are located.

From the disc ground surface or back edge of hilt as a locating point a number of parts are set on end as shown by Fig. 13, and resting them on the angular surface A at sides, they are clamped against block B, by expanding Jaws C. A fixture full of these parts is milled at one setting by the use of a formed cutter D.

In locating the work in the fixture, Fig. 14, it is obvious that the work will be milled on an angle. At this time two cutters are used, one being a long surface mill for machining the side while the other is a short one which cuts out the recess in side long enough to permit the cutter that mills straight across the recess to clear the corner of the angle.

In this tool the work is located at A from the end previously machined and the disc-ground side is clamped against block B by bolt C, and strap D. One piece only is held in each fixture but two of these are mounted on a swivel plate side by side as shown by dot and dash lines in plan view. At the completion of cut on one part the table is indexed to bring the other fixture previously loaded under the cutter, thus providing continuous milling.

For milling the opposite side a fixture similar to that shown by Fig. 14 is used. This fixture, however, is made to the opposite hand; the two fixtures being known as right and left hand.

What proves to be a very economical fixture is shown by Fig. 15, this being used for milling form at end of prongs and the step. It will be noticed on this tool that two rows of hilts are set on ends using the back edge A and bevel at sides for locating. When placing the work in position the pins C (one for each part) are forced up and locked by screw D, springs being used to force the pins up. This holds the work against the locating surfaces while every two hilts are clamped against fixed block E by expanding blocks F, which are forced open by screw and tapered bushing G. This securely grips the work as there is but two thousandths of an inch variation in thickness allowed. As many parts as possible are placed in one fixture and these are rapidly milled with a gang cutter H.

To obtain the form at front edge of hilt a form milling cutter is run across the length and this edge is afterwards ground slightly convex. While form milling, the hilts are held in the fixture, Fig. 16, being located from back edge.

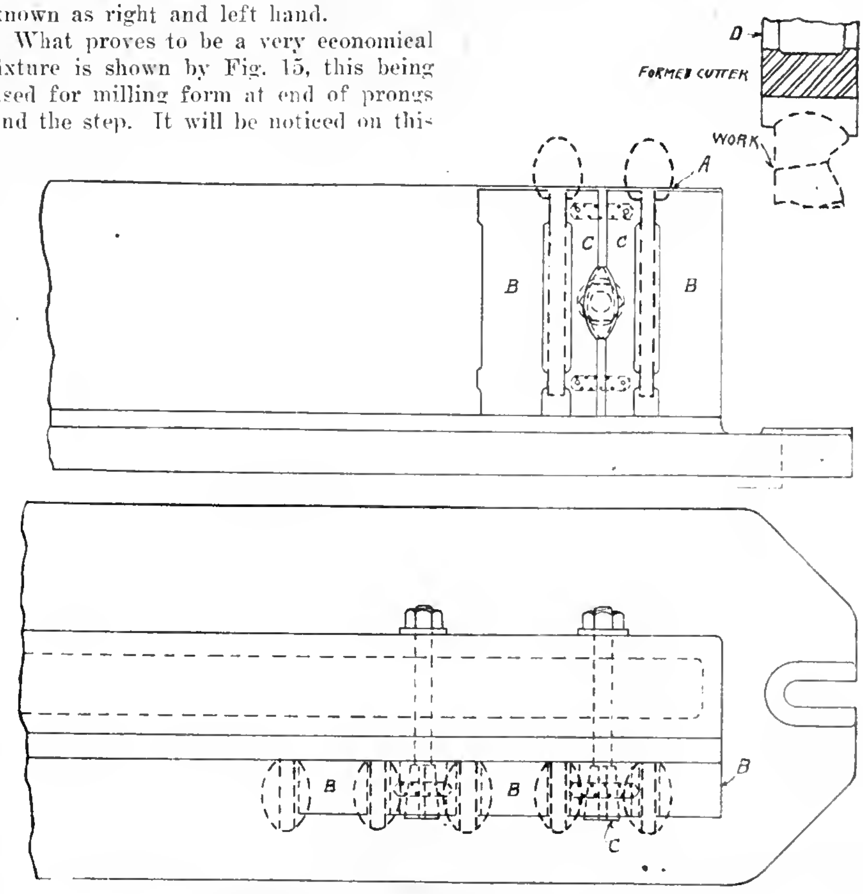

FIG. 13—MILLING ENDS OF HILT IN GANG FIXTURE

sides and angular surfaces while the clamping is done by expanding jaws A operated by stud B through eccentric and draw bar C in a manner which is readily understood from the illustration. The tee slots in hilt are cut on a vertical hand milling machine with tee slot cutter in the usual manner. A vise with special jaws being used which grip the work by the side.

In succession all holes in hilt are next drilled and counterbored and the slot Z Fig. 12, is milled out with an end mill while a small corner left by end mill is slotted out. These operations are profitably performed by using simple fixtures which adapt the work to various machines that are available.

To mill relief in sides of hilt reference is again made to Fig. 14 as similar tools are used with the exception that the work is held straight while feeding under cutter as shown in diagram Fig. 17. The work in this fixture is located from the bevel instead of from end as in the former case. The brace which has supported the open end of prongs is now milled out in a fixture of the same type as that shown in Fig. 15.

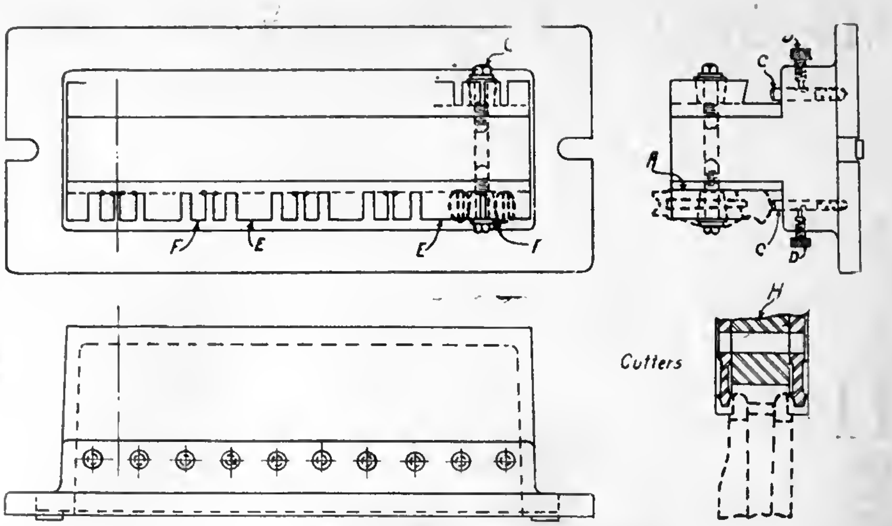

FIG. 15—GANG MILLING CUTTER FOR END

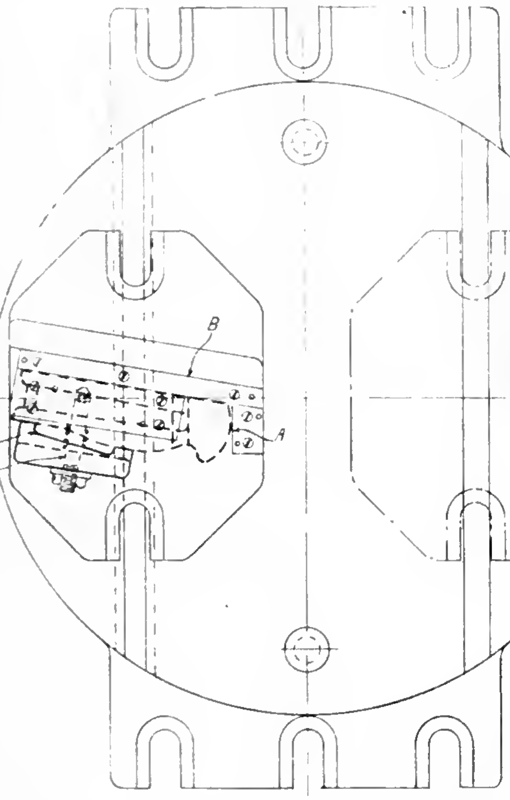
To mill the inside of prongs a fixture of more than usual interest is used to hold the hilt and this is shown by the illustration, Fig. 18. This provides for locating the work by back edge A and vee B on the side in block C. The screw D secures the work in the vee while the clamps on top securely hold both prongs under the cut. The fixture proper E is mounted on a plate and pivots on stud F. In this plate are two holes G and H, into which an indexing pin is fitted.



In operation the fixture is set with the index pin in one hole, after which the fixture is securely clamped by the bolt I. The cut is then taken down one side of the inside of prong with a formed mill held in a vertical spindle milling machine. Following this the fixture is indexed to the next hole and a cut is taken on the opposite side.

The final operations are hand performed and consist of grinding unfinished portions to shape, removing a small fin which is at open end of prong and is left by the previous operation, and removing all burrs by filing.

It will be noticed that there are two half holes in the hilt as shown in Fig. 12, and these are drilled when assembling bayonet.

The guard crossing, having to fit with the other parts of the bayonet in but one place in addition to fitting the barrel of rifle, more liberty can be taken with the machining of this part than with the blade and hilt.

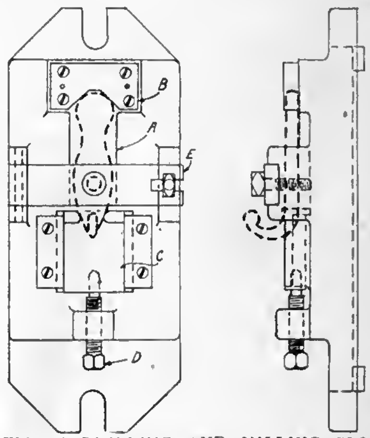


FIG. 19—DRILLING AND MILLING SLOT IN GUARD

The guard as shown by Fig. 12 is a mild steel drop forging restruck to make it fairly accurate to size and is machined as follows: The inner side A is disc

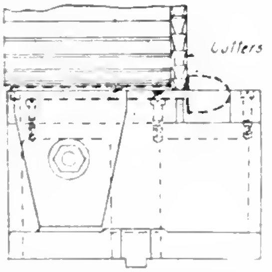

FIG. 14—MILLING SIDE OF HILT USING TWO FIXTURES ON A TURNTABLE

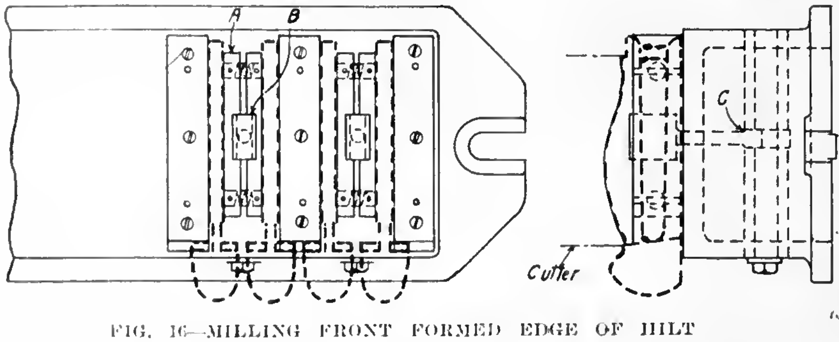

FIG. 16—MILLING FRONT FORMED EDGE OF HILT

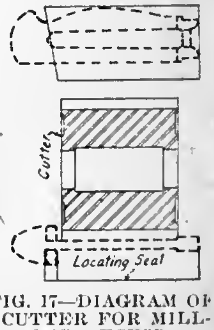

FIG. 17—DIAGRAM OF CUTTER FOR MILLING RECESS

ground and by laying a number of guards on a specially constructed magnetic chuck, the opposite side B is ground to thickness on a surface grinder.

Following these operations the guard is held in the jig, Fig. 19, and a hole is drilled as shown at A, Fig. 20. This is followed by milling the slot as shown in the middle view B, with end mill in vertical milling machine, both of these operations being performed in the same tool, Fig. 19. This fixture is used in the following manner: After laying the guard as shown in the illustration on pad A, and locating round end in vee block B, the work is clamped by means of the sliding block C operated by the screw D. For guiding the drill a swinging cover E is used which contains a guide bushing and this is swung out of the way when milling, thus permitting the use of a short stiff end mill for cutting the slot.

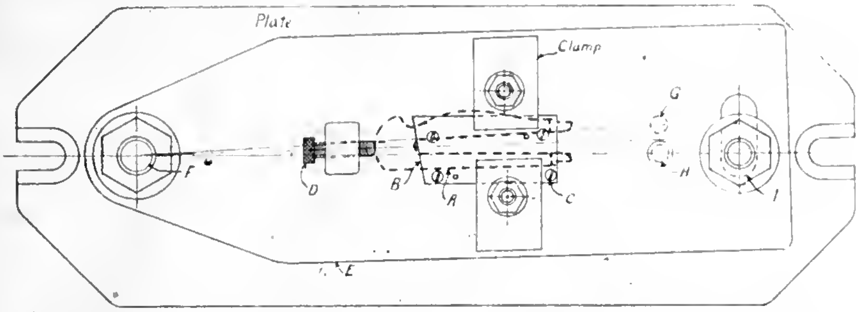

FIG. 18—PLAN VIEW OF FIXTURE FOR MILLING INSIDE OF PRONGS

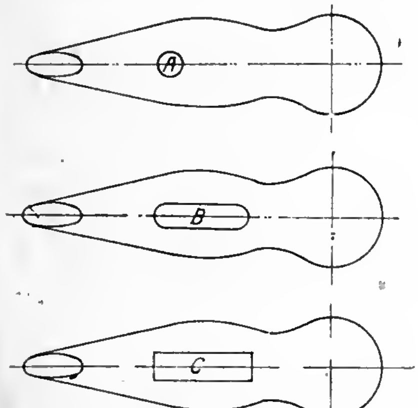

FIG. 20. DIAGRAM OF OPERATIONS ON SLOT IN GUARD.

The guard is next broached in the usual manner by drawing a long broach through the hole roughed out, thus leaving the hole with square corners as shown at C, Fig. 20. The outline of guard is now trimmed by grinding in the usual manner as required to finish off a rough forging.

To insure accurate assembling of the completed bayonets the three remaining holes (two small half holes and large hole) are drilled at assembly.

The assembling of the bayonet is done in a simple and effective manner while permitting an easy means of taking same apart and it would not be a difficult matter to pick up any part of a bayonet on the field to repair a broken one. With the exception of the parts previously described the other details are shown by Fig. 21.

To commence assembling the two plates A, Fig. 21 are pinned in place at A, Fig. 22, and following this the guard crossing B is forced in place, after which the tongue of bayonet blade C is positioned as shown between the plates.

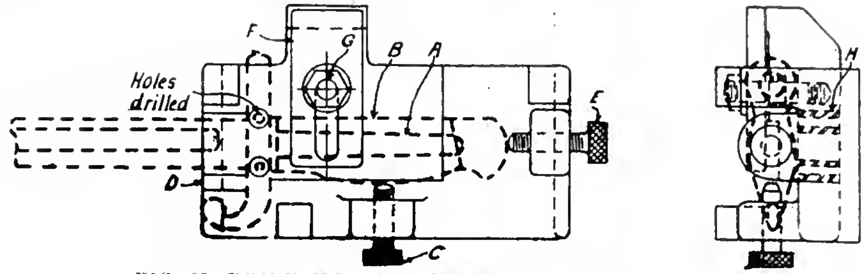

FIG. 23—DRILL JIG FOR ASSEMBLING GUARD TO HILT

To prevent the blade from pulling out of hilt a pin D is driven through the bayonet tongue to butt against edge of plates.

The holes E are drilled in jig, Fig. 23, at which time the hilt rests on seat A, pushed over against back edge B, with screw C. The guard sets against block D, and is held there by screw E at end of hilt which also forces hilt into guard. The clamp F and screw G hold the work in place while the jig is turned over and the holes are drilled through bushings H on the under side which guide the drill.

Having the blade, hilt and guard securely fixed in place, we proceed to drill the hole in the guard which fits over the rifle barrel, this having been left till the last so it could be located from the tee slot in hilt, which also fits the rifle.

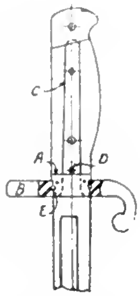

FIG. 22—METHOD OF ASSEMBLING HILT

The jig for this purpose is made in two parts owing to the length of blade, and consists of a template A, Fig. 24, and a block B, on which the work is set. This template jig is made to slip over bayonet hilt with C located in tee slot until the surface D rests on guard crossing, in which position screw E holds the jig back against the edge of hilt. The jig and bayonet are now set on the block B in the drill press and the hole is spotted, drilled and reamed using the bushing F for guiding the tools.

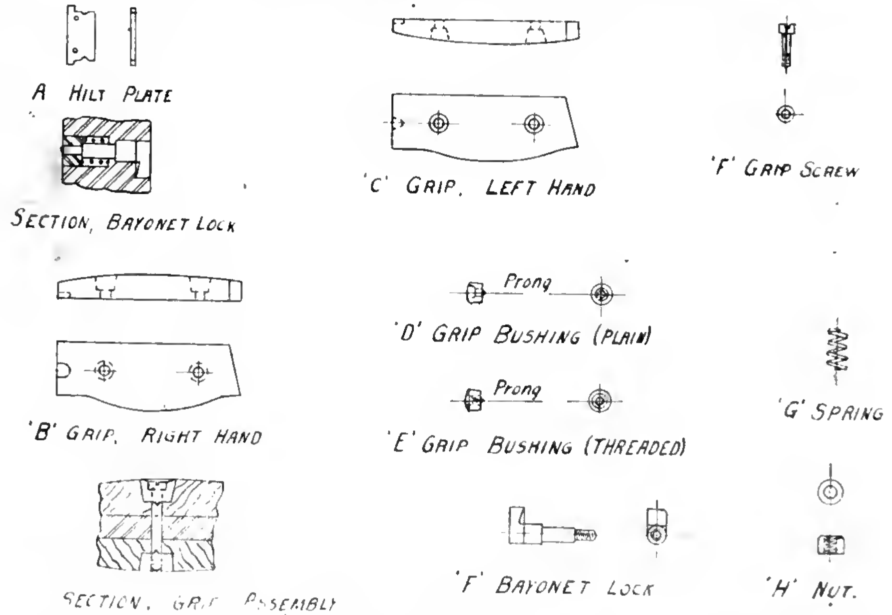

FIG. 21. DETAILS USED TO COMPLETE BAYONET CONSTRUCTION

The main parts of the bayonet being now taken care of it is only necessary to assemble the grips and bayonet lock.

Again referring to Fig. 21 for details of these parts, the grips, one right and one left hand, are next put in position

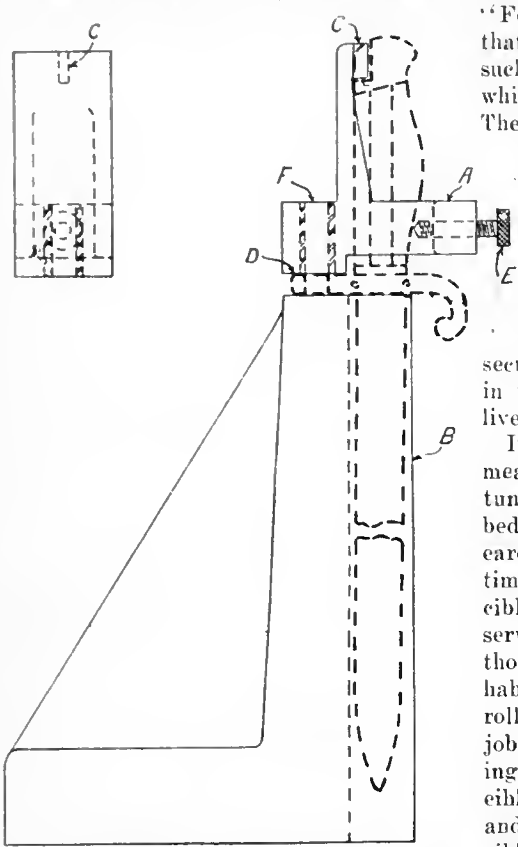

FIG. 24—JIG AND BLOCK FOR DRILLING HOLE WHICH GOES OVER RIFLE BARREL

and held in place with two of the screws shown, also one each of the bushings are used with each screw, a plain drilled bushing at the head end and a threaded bushing at the opposite side as shown by the section "grip assembly." It will be noticed that a short prong is made on each bushing so they will embed in the grips when the screw is tightened

The assembling of the lock is shown in section and the various details, locking bar, spring, and nut are assembled in the order named and require no special mention all of these small parts being made in the usual manner for screw machine parts.

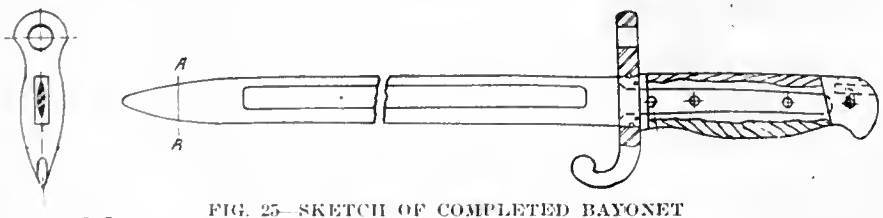

FIG. 25—SKETCH OF COMPLETED BAYONET

The assembled bayonet complete in detail is illustrated by Fig. 25, this result having been quickly and accurately obtained in a way which insures interchangeability of product between parts of the bayonet, and between the bayonet and rifle which is very desirable and in line with modern gun work.

CRUCIBLES

THE life of the Crucible Maker is not the halcyon, care-free existence that "Foundry Folk" possibly have in mind that it is. Leastways it has not been such for many, many weary months, which have been mostly dark nights. The proper clays and the securing of such in sufficient quantities is what has troubled the crucible maker. This, in fact, is "The Crucible Rock" upon which all their hopes and efforts have been wrecked. But at last the sky is clearing. Clays of more satisfactory sorts have been secured, and with their use better results in the foundry will be had and longer lived crucibles will result.

It rests, however, with the user, in a measure to improve the present unfortunate state of affairs and this can bedone in the following ways:—Greater care must be given in annealing—more time must be consumed, after the crucible is received, before it is put into service, and smaller crucibles used than those which the foundry has been in the habit of using. In past years all brass rolling mills, crucible steel casters and jobbing shops thought nothing of having six months or a year's stock of crucibles ahead of their wants—seasoning and drying. To-day, no sooner is a crucible received then it is put into active service.

The native clays now used by the crucible maker have made the crucible more frail and tender than were those made from foreign clays,—more likely to crack on sudden heating and cooling. Therefore, more than ordinary care must be used by the melters in the handling of American clay made crucibles.

Crucibles should not be cooled down too rapidly, any more than should the heating up be done too quickly. It is a good plan to return the crucible while it is still hot, after the day's work is done, to the furnace from which, of course, the coal has been dumped. By doing this, the strain in the cooling will not be as severe and the crucible will not crack so early in its life.

The smaller the crucible is the greater are the number of heats that can be secured. Therefore if a crucible of a size or two smaller than what is generally used is adapted, better values and less disappointments will be the results. For instance, if a foundry uses a No. 400 pot, let them adopt a No. 300 or a No. 225, or in a shop where No. 60's are the rule, let it be a No. 45 or a No. 50. In this way both caster and crucible maker will be relieved of the hundreds of annoyances and complaints that for the last few months have made their bed—one of roses, with the petals, buds and flowers all plucked off.

CONCERNING ANTIMONY

A BRITISH Consular report contains an interesting reference to the effect of the war upon the supplies of antimony:

The war, says the report, had not been long in progress before it became evident to all concerned in the manufacture of explosives that the Province of Hunan in China actually controlled the total visible supplies of antimony then existent, and in order to obtain this much-needed metal, Hunan prices would have to be paid for it. Before the war the value of antimony regulus on the London market was about $125 per ton. It had long been assessed by the Chinese Customs for the purpose of export duty at about $50 per ton. The price has now risen to over $500 per ton, but the Customs rate remains the same.

Previous to the outbreak of the war the whole output of the pure metal, as refined by the Hua Chang Co. of Changsha, which enjoyed a monopoly of the manufacture of regulus in Hunan province, was controlled and marketed in London by a British concern, under a time contract. In times of peace and normal prices, this arrangement offered many advantages to the Chinese manufacturers, but after the outbreak of the war their interests lay in quite another direction. Temporary banking difficulties having arisen with the war, the Chinese refiners of the metal seized the opportunity to denounce the contract.

Soon afterwards market quotations for standard metals were stopped in the United Kingdom, and the export of antimony prohibited. Owing to the use made of it for the manufacture of munitions of war, it was declared to be contraband, and its transport by land or sea closely watched and restricted. The area within which it was produced in France was invaded by the Germans, and thus cut off from the world at large, as was also the output from Austria-Hungary. The Bolivian and Mexican mines having closed down, only two or three minor sources of direct production remained as possible competitors to the one important producing area left, that is to say, the Chinese Province of Hunan. From both foreign and Chinese sources of information, the real state of affairs soon became known to all the Chinese interested in the trade, and when an urgent demand arose in Japan, Russia, America and the United Kingdom, the Chinese seized their opportunity, held up supplies and concerned the market

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

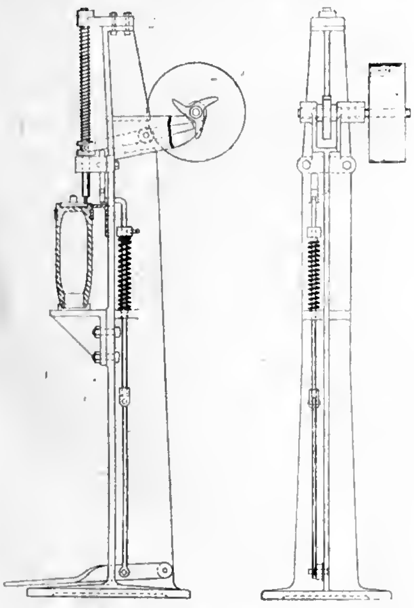
HOME-MADE RIVETER FOR SHELL PLUGS

By H. P. Hoag

THE riveting machine shown in the drawing was brought out to rivet gas plugs in 4.5 shells and owing to its simplicity and efficiency the writer believes it will be of interest to others on a similar line of work.

The action is as follows: The vertical spindle is lifted by the horizontal lever and the three-lobed cam on shaft at back and is allowed to fall by its own weight plus the pressure exerted by the spring on the upper end of spindle.

No countershaft is required as the cam shaft with pulley may run continuously by being belted direct to line shaft. The hammer is started simply by pressing down on the foot lever which releases the horizontal lever reaching from cam to vertical spindle. When the foot



HOME-MADE RIVETER FOR SHELL PLUGS.

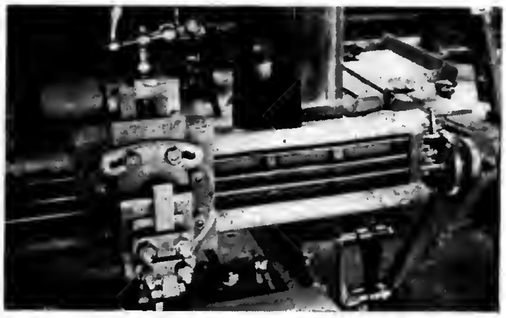
lever is up the horizontal lever is held out of action of the cam by a rod and stiff spring shown on drawing.

Speed of pulley is about 200 per min., giving 600 blows per min. The machine has an output of 100 shells per hour.

CROSS-CUTTING ON A PLANER

By D. A. Hampson.

THE photograph shows a rig for taking light cuts at right angles to the normal cut of a planer, i.e., across the table. This same arrangement would not work on another kind of planer drive, but with the machine being considered, it is ideal. The usual open and crossed belts drive pulleys that are connected to the first shaft by clutches giving the ordinary reverse, and a clutch on the shaft can be thrown out to cut out the table movement and apply power to the pulley raising the cross rail.



CROSS SLIDE ON PLANER ARRANGED FOR TRANSVERSE MACHINING.

By slipping off the power elevating belt, we had a reversible shaft in line with the cross-feed screw, and by putting a pulley on each and belting them up, we had a power cross-cut with sufficient power to take a chip ½ in. wide and 1/64 in. deep in cast iron.

Some of the work was surfacing cast iron plates that would just pass through the housing when bolted down the one way, but were too long to pass the other way. Slots were required across the castings in several places, and the power cross-cut was a means to do all the cutting at one setting, and avoided the use of an extension head, making a nice saving of time.

ELECTRIC FURNACES

RAPID progress is being made in the adoption of electric furnaces by metal manufacturing concerns in Britain, a number of units for ferrosilicon as well as steel having been recently installed by the Snyder Furnace Co., Chicago. During a recent visit by W. K. Booth, vice-president of company, four ferrosilicon furnaces were installed in a remodeled plant, having a power consumption of 1,800 k.w. and producing silicon with a purity of 97.25 per cent. Recent British purchasers of Snyder electric furnaces include: Thwaites Brothers, Bradford, two 12-ton basic furnaces; Thos. Summerson & Sons, Darlington, one ditto; Daimler Motor Car Co., Coventry, special grey iron furnace for automobile cylinder castings; National Steel Foundry Co., Leven, Fife, special 5-ton basic furnace.

QUESTIONS AND ANSWERS

Question.—When the centre of an arc is not available, as in a large fillet or broken wheel, how can the radius of arc or diameter of wheel be determined?

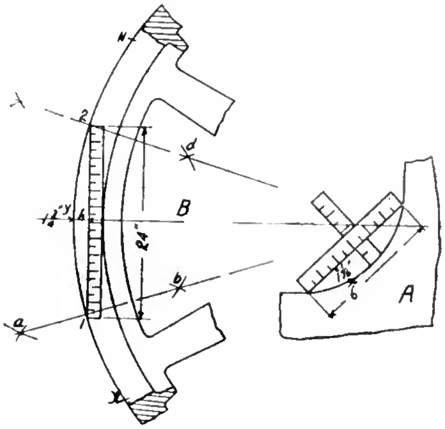
Answer.—A good rule to calculate the diameter of a fillet when only a section of the circumference is available is to divide the sum of the square of the height and the square of half the chord by the height. For example, in the sketch of the fillet shown at A a six-inch rule is laid across the fillet and the height of the opening is found to be 1 1-16 inches. From the above rule the diameter would be

$$\frac{3^2+1.0625^2}{1.0625} = \frac{10.129}{1.0625} = 9.533 \text{ inches.}$$

The same rule applied to the flywheel section shown at B would be

$$\frac{12^2+1.75^2}{1.75} = \frac{147.06}{1.75} = 84.04 \text{ inches.}$$

The centre of the arc can be determined graphically by selecting three points on the circumference, as x, y, z.



Bisecting these distances as shown, the intersection of the produced lines will be the centre of the arc or circle of the original wheel.

* * *

Question.—What is specific gravity, and how can it be used to calculate the weight of different substances?

Answer.—The specific gravity of a body is the ratio between its weight and the weight of a like volume of distilled water at a temperature of 39.2 deg. F. To find the weight of any liquid or solid, when its specific gravity is known, multiply the specific gravity by 62.5, the weight in pounds of a cubic foot of water. For example, if the specific gravity of cast iron is known to be 7.21, the weight of a cubic foot would be 7.21

$\times 62.5 = 450.6$ pounds; or weight per cu. inch would be $450.6 \div 1728 = .26$ pounds or 4.16 ounces.

* * *

Question.—What would be the weight of the metal forming the fillet in the right angle corner of an iron casting, radius of fillet being $1\frac{1}{2}$ inches and the total length $7\frac{1}{2}$ feet?

Answer.—The area of the cross section of the fillet would be one-fourth the difference between the areas of a 3-inch square and that of a circle 3 inches in diameter, or $\frac{1}{4}\ [9 - (3^2 \times .7854)] = .483$ inches. Volume of metal would be $7.5 \times 12 \times .483 = 43.47$ sq. in. Then weight would be $.26 \times 43.47 = 11.3$ lbs. .26 is the weight in pounds of one cubic inch of cast iron.

* * *

Question.—With a tensile strength of 60,000 lbs. per sq. inch, and a factor of safety of 5, what would be the limit of load on a ⅝ rod?

Answer.—With the above safety factor of 5, the limit of load would be 60,000 lbs. divided by 5, or 12,000 lbs. per sq. inch. For a ⅝ rod this would represent a load of $12{,}000 \times \frac{5}{8}^2 \times .7854 = 3684$ pounds.

* * *

Question.—With the cutting tool set level with the centre, what fraction of a turn would be required by the cross feed handle to remove 1-16 inch of stock on the diameter, cross feed screw having six threads per inch?

Answer.—To remove 1-16 inch of stock will require an advance of the cutting tool of 1-32 inch. As the pitch of the cross-feed screw is 1-6 inch, the fraction of a turn will be $1\text{-}32 \div 1\text{-}6 = 3\text{-}16$ of a revolution of the cross-feed screw.

* * *

Question.—When preparing dies for hardening it is often desirable to fill small holes with non-combustible material, to avoid loss by breakage. What is the best method to remove this filling from small threaded holes?

Answer.—In many cases it will be found that the hardening process has reduced the size of hole to a degree where it is difficult to clean the threads out with the tap. If the original tap is used, there is danger of breaking, and in any event it is not advisable to do this, as the hardened die will have a tendency to wear the tap, thus altering the size. An old worn tap may be used; or by taking the proper size screw and cutting a groove across the threads the tapped hole can be cleaned out very readily.

* * *

Question.—With a belt speed of 380 feet per minute on a 9-inch cone pulley, and a gear ratio of 8 to 1 between the cone and the spindle, what time would be required to travel over a $9\frac{1}{4}$-inch diameter shaft, 27 inches long, with 1-16-inch feed; and what would be the cutting speed in feed per minute?

Answer.—With a belt speed of 380 feet per minute the speed of the cone pulleys would be 380 divided by the circumference of the pulley in feet or $380 \div (\frac{9}{12} \times 3.1416) = 118.8$ rev. per min.

With a gear ratio of 8 to 1 the speed of work or lathe spindle would be $118.8 \div 8 = 14.85$ revolutions per min. The cutting speed would be number of revolutions multiplied by the circumference, or $14.85 \times \dfrac{9.25 \times 3.1416}{12} = 35.9$ ft. per minute.

Time required to travel over 27 inches of shaft will be the length divided by the feed, and again divided by the revolutions, or $\dfrac{27 \div 1\text{-}16}{14.85} = \dfrac{27 \times 16}{14.85} = 29.09$ min., practically one-half hour.

* * *

Question.—To lighten a large iron punch casting, which was giving trouble on the press, it was necessary to drill a number of holes to reduce the weight; 48 flat bottom holes, 1⅜ inches in diameter, were drilled to a depth of $1\frac{1}{4}$ inches. What weight of material was removed?

Answer.—The volume of each hole will be the diameter squared multiplied by .7854, multiplied by the depth, or $1.375^2 \times .7854 \times 1.25 = 1.86$ cu. in. Then volume of 48 holes will be $1.86 \times .48 = 89.28$ cu. in. With iron weighing 26 lbs. per cu. in., the weight removed would be $.26 \times 89.28 = 23.4$ pounds.

* * *

Question.—On a piece of shafting, 11 inches long, it is required to cut a groove having 16 complete turns; if the lead screw of the lathe is 4 threads per inch and the gears advance by 4 teeth, what gears are required to cut the desired groove?

Answer.—With 16 turns in 11 inches, the pitch of the groove will be $11 \div 16 = 11\text{-}16$ inch; or the number of threads per inch will be $16 \div 11 = 1\ 5\text{-}11$. With a lead screw of 4 threads per inch, the ratio between the work and the lead screw will be as 1 5-11 is to 4, or $1 : 2\frac{3}{4}$. Then the gear wheels must have the same ratio, and as they advance by fours, try 24 for the lead screw gear. This will give for the spindle gear one of $24 \times 2\frac{3}{4}$, or 66 teeth. However, as this is not divisible by 4, we will select 32 as the gear for the lead screw, which gives $32 \times 2\frac{3}{4}$, or 88. Then the wheels required are 88 on the spindle and 32 on the lead screw.

Proof—$88 \times 1\ 5\text{-}11$ should equal 32×4, then $88 \times 16\text{-}11 \div 32 \times 4 = \dfrac{88 \times 16}{32 \times 4 \times 11} = \dfrac{1408}{1408} = \dfrac{1}{1}$

* * *

Question.—When grinding twist drills, what are the chief points to be considered?

Answer.—For the successful operation of twist drills many details should be given attention; in fact, the proper grinding of twist drills is one of the essential details in machine shop practice. When possible gauges should be used to obtain the proper angle and length of each cutting edge. This angle should be about 59 degrees and the length of both cutting edges should be equal. In addition to this, the clearance should be equal on each side, and should be about 12 degrees. With an experienced drill operator these points are very accurately determined without the use of gauges, as the trained eye and hand performs the work almost perfectly.

* * *

Question.—What is the difference between the terms stress and strain?

Answer.—Stress is that force within a body which resists the action of an externally applied force; while the strain is the deformation, or change of shape, produced by the applied force, and is proportional to the stress within the elastic limit.

SUBSTITUTE FOR SULPHURIC ACID IN PICKLING

A CIRCULAR issued by the Research Mfg. Co., Philadelphia, points out that the elimination of sulphuric acid fumes is accomplished and many other advantages are attained in the pickling of metals for the removal of scale or oxide by the use of a compound which was perfected in the mills of the Ellwood Ivins' Tube Works, Philadelphia. It has been in use in the tube works for some time, but until recently was held as a shop secret. It has been named Edis Compound.

The compound is shipped in the form of dry cakes or lumps which are dissolved in water almost up to the boiling point. It is essential that the solution be very hot, and when being worked about 200 deg. should be maintained. To accomplish this end, the Research Mfg. Company suggests that the free end of a live steam pipe be inserted into the pickling tub, letting the steam condense in the solution. Where the tubs are very long the pipe may be tapped in several places. A piece of copper pipe should carry the steam into the solution.

It is also recommended that the tubs be covered, as this serves to keep the solution hotter, though this is entirely a measure for economy. It is pointed out that it is desirable to make the covers in sections to permit of easier handling. The solution is applicable to iron, steel, brass, copper, etc.

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

EVOLUTION OF THE CUTTING EDGE

In the course of a carefully prepared paper, contributed to the "Iron and Coal Trades Review," Albert Middleton traced the evolution of the cutting edge from the earliest times, and the various methods adopted to secure its efficiency.

Coming down to modern times, the author said that in an article published some time ago in the above periodical, he embodied the results of a research made on some Chinese native made tools. It was pointed out that in a certain crudely made native razor of about 0.70% carbon steel, the value of its cutting edge lay in the fact that, speaking from a micrographic point of view, the edge in the finished condition being composed of an unsaturated steel, not hardened and tempered at a very high temperature, presented minute alternations of ferrite and solid solution—or, in other words, uncarbonized and carbonized material—and these softer portions wearing down below the others, leave the harder portions outstanding as teeth.

Modern Research Revelations

Modern research, however, has revealed the fact that the finest type of razor edge is secured by the adoption of a supersaturated steel, say, 1.40 per cent. carbon, which, by the mechanical treatment it gets in the forging operation, at a temperature where the cementite begins to separate out progressively, has that cementite broken up by the hammer into finely disseminated granules, the result being that when care is exercised not to interfere with this structure in the subsequent hardening and tempering processes, the edge of the tool presents extremely hard, alternating areas of cementite and solid solution, which, on account of the different hardnesses of these constituents, wear down unequally in the subsequent sharpening processes, and present extremely minute outstanding teeth, or really a finely serrated edge. It will be seen from the above that if the razor were hardened at a temperature where all the cementite thus formed passed again into solid solution, this effect would be destroyed.

Whetting a Penknife

It is interesting to note the effect of whetting a fine penknife blade, as seen under the microscope. Before whetting, the edge presents irregularities due to the comparatively coarse abrasion received from the grindstone, and, moreover, shows no minute bevel towards the edge, being practically a plane surface from edge to back. The function of whetting on the beautifully smooth stones used for the purpose takes away this irregularity, and, what is more important, yields a very fine bevel on the edge itself, finishing off by a very delicate operation which the grindstone itself is too coarse to perform.

The appearance of a newly-whetted penknife blade under the microscope shows the bevel and also the fine lines of whetstone abrasion running in one direction. It is actually doing, on a small scale, what hollow and double-hollow grinding on razors effect on a larger scale, namely, by scooping out or otherwise taking away the superfluous material to present an ultimate edge the two sides of which meet at a more acute angle than would be otherwise possible. Sometimes too great elasticity is presented by these extremely thin blades, with the result that it is found that for heavy shaving a blade of the flat ground type is preferable.

Present Day Applications

The present-day modifications and applications of the cutting edge are legion. In addition to the combined knife and saw edges achieved in such implements as file-cut sickles, bread knives with undulating edges, file-cut spiral cutters as used in textile works for shearing the nap of velvet, carpets, etc., we have quite another type of edge in the machine shear blades used for cutting cold thick masses of steel and iron. In these monster tools the edge is necessarily almost at right angles with the blade, the blade itself being anything up to, say, 2 ins. thick. In these cases the shearing action is largely supplemented and reinforced by the crushing effect imposed upon the blade, which forces apart the material and overcomes its resistance by sheer weight.

It is quite obvious that the cutting principle here is different from that of a keen sharp edge severing fibrous material. Tenacity and consequent avoidance of brittleness are naturally an essential feature in the composition of such shear blades, and the carbon of the steel from which they are made is, therefore, purposely kept moderately low. The same principle is utilized in the high-class punches which are used for punching holes through thick, tough, nickel-steel plating. The tool, though really a punch, has its edges made at a slight angle, to secure a slight shearing effect, and a start having thus been made, the pressure behind the tool forces out the material with a report like a pistol shot.

A similar action also takes place with the circular hot saws used for cutting red hot metal. In this instance the combined ripping effect of the teeth, and the forcing by pressure of a tool of superior hardness through a medium of lesser hardness, produces the separation of the red hot metal. These complicated necessities of modern industry naturally throw an additional burden upon the steel maker, who has had to exercise his ingenuity to evolve materials that will cope with these excessive requirements, and in many cases the various alloyed steels have been used with remarkable success, this being where the expert knowledge of the steel metallurgist serves him in good stead.

Alloy Steels

These special adaptations of alloyed steels constitute quite a modern departure, for though alien metals have been found in steel from the earliest times, their occurrence has been of an accidental nature in most cases, the metal having emanated from the iron ore itself. This no doubt explains, at least in part, the special value attached to certain ancient steels; for example, nickel has been stated to have been found in old Toledo blades.

The scientific application of non-ferrous metals to steel, leading to an exact knowledge of their precise ultimate effect on the working capacities of various tools, and coupled with the application of the intricate heat treatments, has resulted in the production of such wonderful tools as the pneumatic chipping chisel, resisting shocks that would have been undreamt of in Huntsman's day, and those milling cutters of complicated section which the tap of a hammer would suffice to shatter, and yet which will worm their way through the toughest steel. These alloyed steels have finally culminated in that marvellous product of the present day—high-speed steel.

High-Speed Steel

It is, indeed, a far cry from the flint of the savage to the high-speed lathe tool of the modern engineer, not only in the amount of work performed, but in the manner in which the result is obtained, and were it not for the service rendered by the microscope, and the involved researches made by latter-day metallurgists amongst the varied fields and systems of heat treatment, we should still

be practically in the earbon steel age.

The discovery, however, that certain essential critical points of a high-speed steel occur in a much higher range of temperature than do those of carbon steels; and that, moreover, these points, instead of developing suddenly, as in the pearlite to solid solution calescence of a carbon steel within the limits of a very few degrees, only develop progressively over a very wide amplitude, make it possible for such a lathe tool to be put to work on a shaft, and to turn off material so heavily and rapidly that the nose will become red hot without detriment to its working capacity. This seeming paradox is due to the fact that the temperature obtained at a low red heat is under the actual temperature required to exceed the change point of the steel, and reduce it from the hardened to the unhardened condition.

In conclusion, it is interesting to note that the modern milled twist drill, that highly ingenious tool, with its delicate spiral, its beautifully accurate and carefully calculated cutting angle and backed-off edge, shaped with the utmost mathematical precision, is merely another adaptation from Nature of the methods of such creatures as the pholas, this small mollusc boring its way through rock by rotating its shell round a fixed point.

FAULTS OF THE SMALL ELECTRIC ARC FURNACE

by W. M. McKnight

THE small electric arc furnace is rapidly coming into favor for the production of small highly-refined steel castings, and its advent is welcomed by both the manufacturers of steel castings and the electric power companies. Without going into the merits of the electric furnace as a competitor of the crucible and open-hearth furnace as to the quality of the product or regarding it as a welcome load builder for power companies, I wish to point out some of the handicaps to its universal adoption and successful operation.

The furnaces that are now in operation in several sections of this continent, while differing in some respects in the mechanical construction and electrical demands, all refine the steel by the same chemical process—by raising the temperature of the bath to 2500 deg. C. or better, by boiling the metal to eliminate the impurities, and by the introduction of the necessary refining agents to bring it up to the fineness desired.

Construction and Efficiency

All small arc furnaces are constructed on certain general mechanical lines, as follows: The furnace consists of a steel shell mounted on trunnions for tilting to discharge the molten metal. This jacket is lined with a slightly refractory lining, sufficiently thick to retain the heat; the lining and shell, however, are pierced with port-holes for the purpose of charging the furnace with steel, adding the refining agents, discharging the refined metal, and for inserting the electrodes, and all these port-holes furnish avenues of escape for the heated gases. The electrodes are secured in place by the holders mounted on the tilting shell, and the holder raises or lowers the electrode by hand operation, by hydraulic control or by electric motor control.

In spite of the fact that the electric furnace, to-day, is turning out small castings of a better quality and at a lower cost than by other processes, nevertheless, the over-all efficiency of the best furnaces on the market is far from 100 per cent. There are three principal sources of loss:

Sources of Loss

Electrical.—In the improper delivery of the energy to the metal.

Mechanical.—In the improper design of the furnace shell and ports, to exclude cold air and retain the heat.

Chemical.—The improper combinations of refractory materials, that should be inexpensive in first cost, withstand the intense heat long enough to avoid delays through the interruption of the manufacturing process and not introduce any chemical combination with the metal. Also, there should be found an electrode that will not waste away too rapidly through oxidation, within and without the furnace, as it comes in contact with the air and gases.

Electrical conditions can be improved by supplying the proper current at the proper potential. Mechanical conditions can be improved by re-designing detail portions of the furnace. The chemical conditions can be improved only by exhaustive research and careful study.

Refractories are of two kinds: the heat-resisting linings and the heat-producing electrodes. The heat-resisting linings may be either acid or basic, depending on the degree of heat required for the quality of steel to be turned out. The heat-producing refractories may be either carbon or graphite.

Temperatures and Lining

Merely to melt down steel scrap and turn out castings of semi-steel and low-grade castings of unknown quality does not require a temperature of 2500 deg. C., and for a furnace for this class of work an acid lining of silica is successfully used. To refine the steel, however it is necessary to use a basic lining of magnesite, at least where it comes in contact with the bath, or where the heat would be intense enough to melt down the silica and cause it to run down into the bath and combine with the metal bath or slag and the basic lining thereby changing their character.

The furnace linings can be placed in two ways: Built up with brick work, the bricks made to conform to the shape of the shell and laid up in a basic paste or coal tar binder, or the material for the lining may be made up into a mass and rammed into the shell. The brick lining offers some advantages, inasmuch as it has passed through a glazing process that should prolong its heat-resisting qualities, but it is expensive, particularly if special sizes and shapes are desired, and if the source of supply is remote, and the delivery uncertain.

The rammed lining should be superior from the fact that it is, if properly put in, a monolithic mass, hence there should be little danger of the bath breaking through to the shell, with the resulting damage to the furnace and loss of the batch.

Electrodes and Their Loss

Electrodes are of two kinds—carbon and graphite. Each has its merits. The carbon electrode is the less costly, but has less electrical carrying capacity than graphite, and consequently must be greater in cross-section to deliver the same amount of energy. It therefore has a larger amount of radiating surface, and consequently the saving in first cost of the carbon is offset by the loss in energy dissipated in heat. Owing to the intense heat of the electrode, its surface both within and without the furnace shell loses carbon by its surface contact with the air and resulting oxidation.

The graphite electrode, by virtue of its greater carrying capacity, is smaller in diameter, and offers less surface for radiation of heat and oxidation. The electrode within the furnace shell is subject to further attack by the passage of the electric current through the heated gases to the lining, which, at a temperature of 2500 deg. C., itself becomes a very good conductor of electricity.

Electric steel castings may be better in quality than those turned out by skilled operators with fuel furnaces, but small electric steel castings can be made at a less cost under present conditions, which conditions could be improved, and then the furnaces will be limited only by the capacity of the source of the supply of electrical energy. The field has apparently no limitations, if the chemist can overcome the losses I have pointed out. Formulate a better refractory lining, an electrode that will not waste away except in heating the bath, and utilize the waste gases by manufacturing them into a by-product or by-products.

This certainly is the day for the chemist, and his greatest achievements will be in the electrochemical field. From a paper read at the Annual Meeting of The American Electro-Chemical Society, Washington, D.C.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

SHELL MACHINING EQUIPMENT

Two complete series of lathes for machining 18-pdr. and 4.5 in. high explosive shells have recently been designed by E. R. & F. Turner, Ipswich, England. The 18-pdr. series embraces fourteen machines, the power to drive same requiring a 15 h.p. motor. The 4.5 series comprises twenty-seven lathes, requiring a 35 h.p. motor.

4.5 Shell Equipment

In what follows there is described the operation of a 4.5 shell plant and the construction of the machines which Messrs. Turner supply. In such a plant there are twenty-seven lathes of four distinct types, and these (a) boring; (b) turning; (c) four types may be classified as thread-milling; and (d) wave-grooving machines. Figs. 1 to 4 represent the general construction of the four classes. It will be noticed that in many respects the boring and turning machines are similar, as are the thread-milling and wave-grooving machines. Such similarity naturally facilitates the rapid manufacture of the machines themselves.

Boring and Turning Lathes

The boring lathe, bed and headstock are combined in one iron casting. A large stepped hollow spindle provided with a ball thrust bearing sits within the headstock, and at the left hand end this has keyed to it a spur wheel. This wheel meshes with a pinion on a belt-driven countershaft fixed to the back of the lathe bed. The feed is derived from the spindle by chain and sprocket wheel, and is transmitted through a pair of gear wheels on to the feed shaft along the front of the bed. A dog clutch and hand wheel on this shaft permit the power feed to be interrupted and a hand feed applied. On the end of the feed shaft a dropping worm operated by a trip lever is keyed. This gears yith a worm wheel on a cross shaft carried in a pair of fixed bearings in the bed casting. A pinion on this shaft meshes with a central rack on the under side of the boring bar saddle. A star handle for rapid traverse of the saddle is provided on the cross shaft. Half the bearing for the bar end is formed in the saddle casting proper and the other half in a cap hinged to the saddle casting along its rear edge and pulled up by a bolt at front.

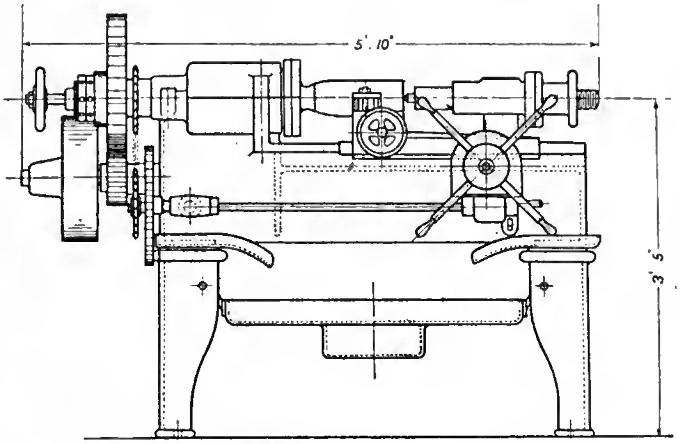


FIG. 2. TURNING LATHE FOR 4.5 IN. SHELLS.

The turning lathe, as will be seen from Fig. 2, is of very similar design to the above. It is modified in so far that the saddle is provided with a hand-fed cross-slide, while an overhung tailstock for the back centre is bolted to the rear face of the bed.

Thread-Milling Machine

The thread-milling machine, Fig. 3, is of radically different design. In this tool the work is fixed inside the hollow spindle of the headstock. This spindle is driven through a worm wheel, a dropping worm and a pair of bevel wheels from a pulley shaft at the back of the bed. The cutter is rotated by a separate belt drive from the overhead counter-shaft, and is mounted on a cross-slide carriage, which gives facilities for racking the cutter into position longitudinally and feeding it into the work to an indexed depth.

With the worm dropped so that the work is stationary, the cutter is racked longitudinally to a thread short of the full length to be threaded. It is then set rotating, and is fed into the metal to the indexed depth. There are thus cut in the metal a series of short parallel grooves, each of which will become the start of a separate thread. The work being started up, its speed of rotation is slow, and during its rotation it is slowly fed forward. Its total feed only amounts to one pitch of the thread being cut and its total rotation to one complete revolution. At the end of this mo-

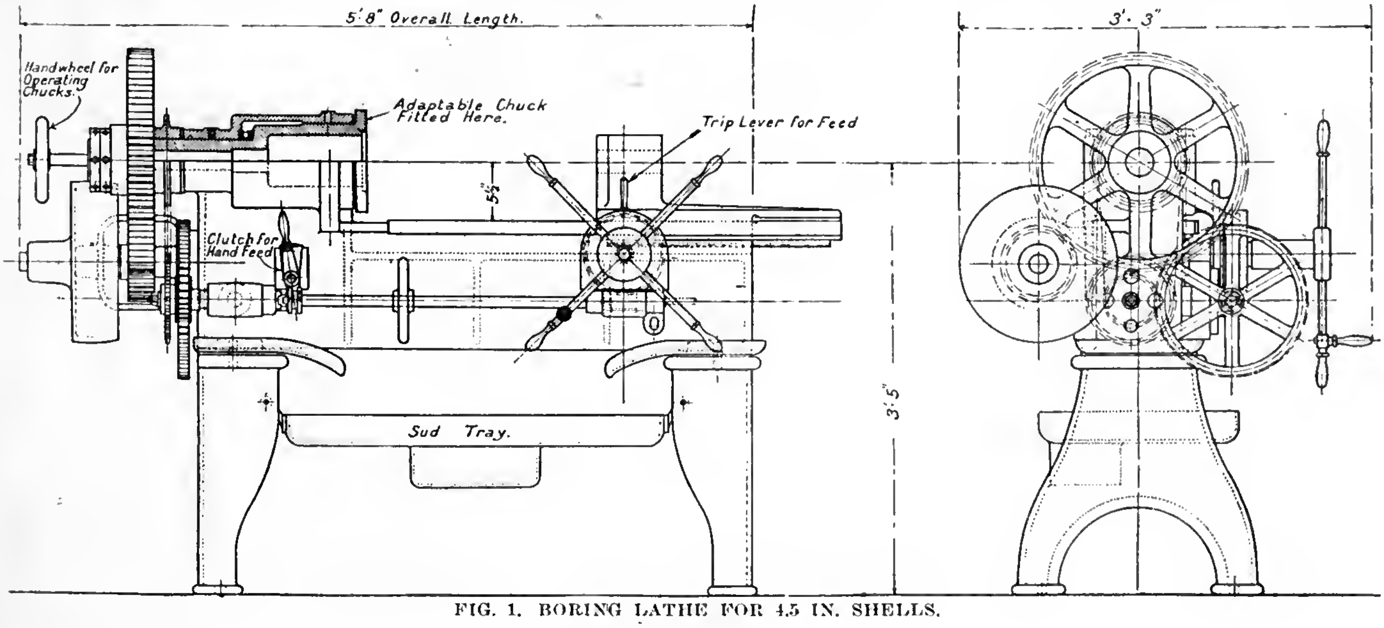

FIG. 1. BORING LATHE FOR 4.5 IN. SHELLS.

tion all the short parallel grooves have been extended round the circumference of the work and have been joined up into a continuous thread. The worm can now be dropped so as to stop the work. The cutter, until it is stopped, will not damage the thread, for it is rotating at that point of the circumference of the work at which it started.

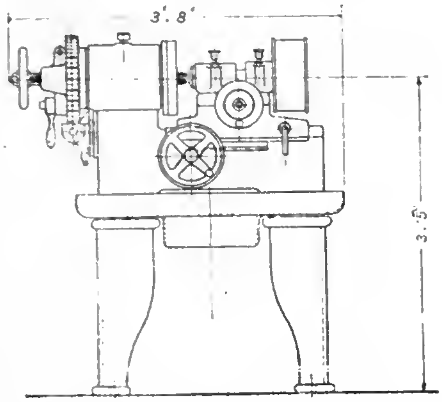

FIG. 3. THREAD MILLING MACHINE.

The advance of the work is obtained by the provision of a thread on the headstock spindle and of a fixed nut for this thread to work in. At the end of a job the headstock spindle can be readily moved back through the small distance it has advanced by dropping the worm and rotating the spindle backwards through one revolution. As the feed does not amount to more than say 1-16 in. the forward movement of the spindle does not upset the drive between the worm and the worm wheel.

The wave-grooving machine—Fig. 4—is somewhat similar to the thread-miller in general appearance. Its spindle, however, is driven directly by belt, while the cross-slide of the saddle carries a four-

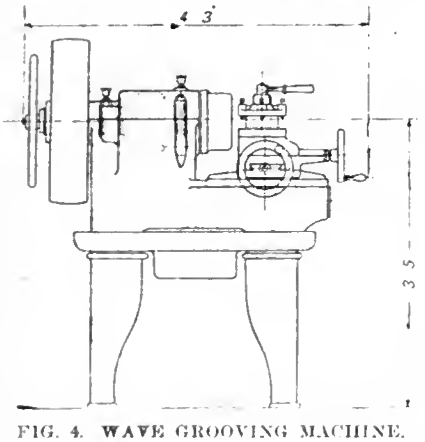

FIG. 4. WAVE GROOVING MACHINE.

tool turret. The tools on the turret are employed to undercut the edges of the groove for the copper driving band and to "wave" the bottom. When waving is being performed the headstock spindle, within which is the shell, is made to reciprocate in the required manner by means of a cam arrangement.

These four types of machine are used to perform all the cutting operations required on the shell body and the nose piece. Each distinct operation is performed on a separate machine, which is kept constantly set for that operation. Some of the operations absorb more time than others. For these the machines are duplicated or triplicated. Although the machines are divisible into four classes, the members of each class are not in general identical. The feat-

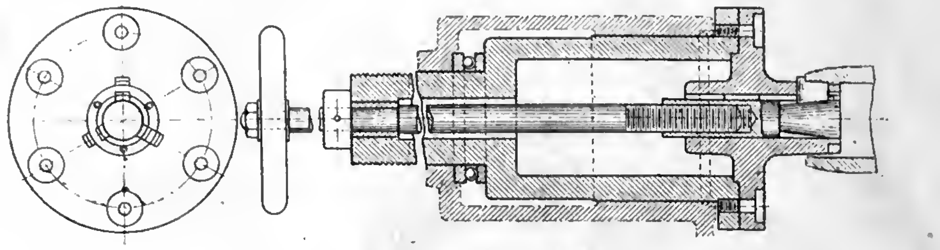

FIG. 6. CHUCK FOR TURNING.

ure of difference is the method adopted of holding the work in the machine. This method is in each case designed with a view to the stage which the work has reached and to the nature of the operation next to be performed on it.

Fig. 5 gives a "program of operations," showing the stages through which the shell and the nose piece pass, and indicating the manner in which the work is held in the lathe in each. The first two operations on the shell body are performed on machines of the turning lathe type. There is one machine for each operation. These latter, are first, cutting off the excess material at the closed end of the rough shell forging, and, secondly, cutting off the excess material at the open end to a gauged length. The third operation, that of forming the "centre" on the closed end, is performed on a 20 in. upright drilling machine. This tool is not supplied by Messrs. Turner, and is not counted in the total of twenty-seven required for the whole plant.

The fourth operation is the rough turning of the shell body. For this three machines of the turning lathe class are provided. The movement of the tool during this operation is controlled by a curved templet, against which a roller on the cross-slide is made to bear. In this way the open end is given an approach to its final curved taper form. The manner in which the work is held during this operation is illustrated in Fig. 6. To the end of the hollow headstock spindle a plate is bolted, through the boss of which there can slide on a key a short cylinder, one end of which is bored and tapped, while the other end is turned as a reversed cone. The tapped portion screws over the threaded end of a pull-up rod which, passing out at the left-hand end of the hollow spindle, is provided with a hand wheel. Three slots are cut radially through the boss surrounding the conical portion of the keyed cylinder, and within each of these a stepped gripping plate is placed. These plates, on the hand wheel being turned, are forced out by the cone against the bore of the shell mouth, and with the back centre establish a complete support for the shell. The gripping plates, on the removal of a finished shell, are held in place by means of a ring fixed to the nose of the boss.

The fifth operation is in three parts, namely, roughing the bore, roughing the bottom, and finishing the bore. To each of these sections two machines of the boring lathe class are allocated. The method of holding the shell in this case is illustrated in Fig. 7. A rod, as before, passes through the hollow spindle, but it does not go beyond the step in this spindle. Here it is threaded into a nut, while a "centre" is let into its end.

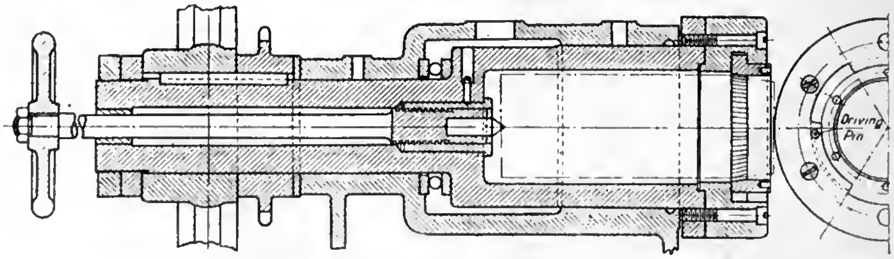

FIG. 7. CHUCK FOR BORING.

The shell, open end out, is inserted within the hollow spindle, and over its nose there is passed a collar, the bore of which is slightly conical and roughened. An outwardly extending flange on this collar is cut down over three alternating sectors. The three projecting pieces of flange thus left can be passed through three corresponding openings in a member bolted to the spindle end.

The collar is now turned through about 60 deg., so that it is held against translational movement by its three lugs.

The radial face of one of these lugs is caused to bear against a pin fixed across its passage in the bolted member, so that the reaction of the cut will not rotate the work relatively to the hollow spindle. With the collar thus fixed the nose of the work is tightened within the bore of the collar by screwing up the centre rod.

Operation six is to mill the thread for the reception of the nose piece. One machine of the thread-milling class is provided for this work. The method of holding the work is quite clearly shown in Fig. 5. The right-hand end of the hollow spindle is provided with a fixed plate bored conically to suit the taper on the shell nose. The shell is inserted from the left-hand end, the opening here being afterwards closed by a hinged breech-block, through which a "centre" is screwed. As shown in Fig. 5, a catch is provided to engage the teeth of the spur wheel on the hollow spindle. This pawl is thrown in when the thread is being started to prevent the work from rotating.

For operation seven — finishing the turned surface—two machines of the turning lathe class are provided, and for operation eight—cutting the closed end to length and forming the groove for the copper driving band—one such machine is installed. The method of holding the work in both cases is to screw the threaded nose of the shell over an easy-threaded arbor on the pull-up rod and to support the other end of the shell on the back centre.

One machine of the wave-grooving class is used for the ninth operation, which consists of waving and undercutting the groove formed in operation eight. The work is held in the hollow spindle by means of a collet chuck, which can be pulled up by an external hand wheel.

Operations ten and eleven are concerned with the roughing and finishing of the recess on the closed end of the shell. One machine of the lathe class is employed for each. The nose of the shell is held within a tapered bush inserted into the hollow spindle. The parallel body part of the shell is embraced by a cap, which is bolted to a suitable member attached to the mouth of the hollow spindle. Between the cap and the chuck member springs are inserted, so that half a turn of the bolt nuts applies or releases the pressure of the cap on the shell.

For operations twelve and thirteen, machines and appliances not supplied by Messrs. Turner are required. The former operation consists of inserting the base plate into the recess and riveting it therein by means of a pneumatic hammer. The latter operation covers the pressing on the copper driving band and its compression into the waved groove. Various methods of pressing on the copper band of a shell have been devised. In the illustration, a hydraulic one is indicated, the apparatus consisting of a hydraulic cylinder and four dies connected to toggle links so as to act simultaneously on the copper band when the ram of the cylinder is elevated.

A modified machine of the wave-grooving type is used for operations fourteen and fifteen. These operations consist of turning the exterior of the copper band to the correct form and of facing off the riveted-in base. One machine is employed for these two operations. The shell is gripped as in operation nine by means of a collet chuck, and the machine is otherwise identical in design with the wave-grooving and undercutting lathe except that the cam arrangement for reciprocating the work is not required.

The nose piece is now screwed on to the shell, when the whole is ready for the sixteenth and last operation. This consists of chamfering the edge of the fuse hole in the nose and of finishing the external form of the nose piece to the required curve and blending this curve into the curvature of the nose end of the shell body. One machine of the boring type is employed on this operation. The shell is held in the hollow spindle by means almost identical with those used in operation five. The chamfering and blending operations are conducted simultaneously. The chamfering is performed by a countersink tool held in the boring bar support. The blending is conducted with a tool in the form of a plate ground to the required curvature and carried in an L-shaped bracket, which is fixed to the boring bar support. — The Engineer.

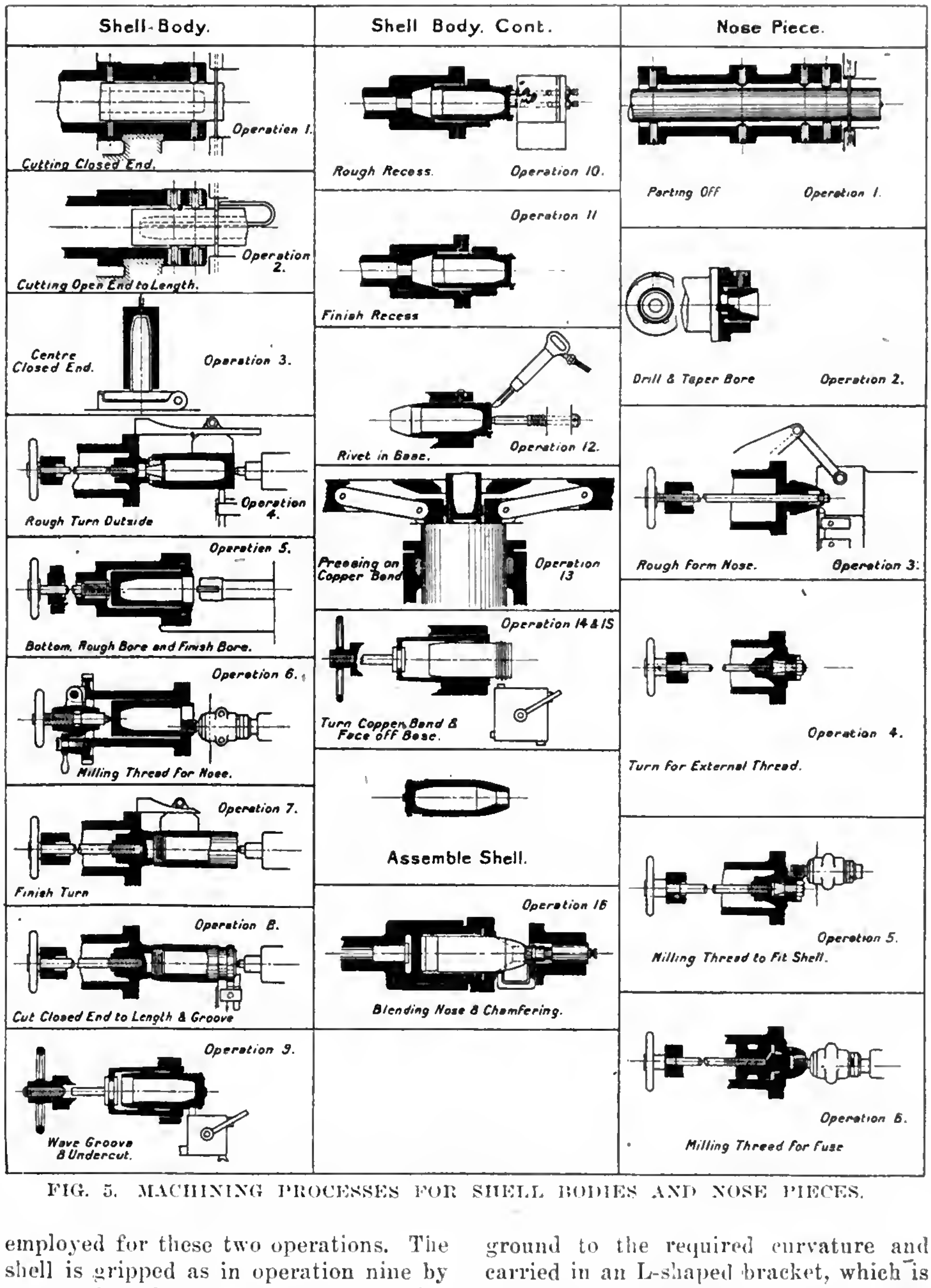

FIG. 5. MACHINING PROCESSES FOR SHELL BODIES AND NOSE PIECES.

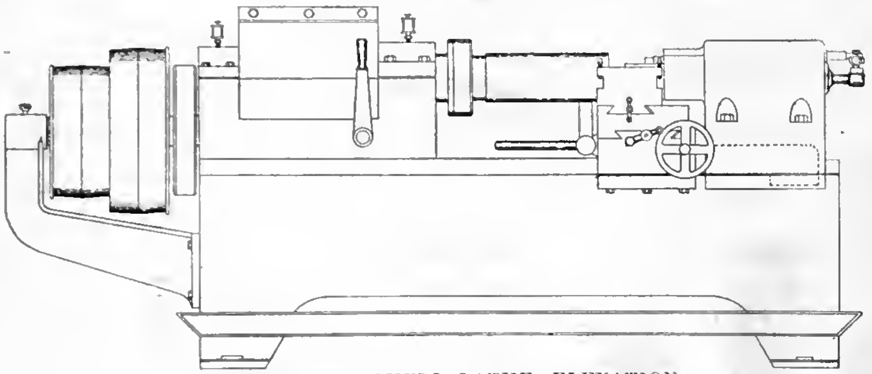
Welland, Ont.—A deputation from Stamford town and township councils will ask the Dominion Government to construct a navigable canal and turning basin at a point near Lundy's Lane, connecting with the Welland Ship Canal.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

THREE-SPINDLE SHELL LATHE

THE accompanying drawings illustrate a three-spindle shell turning lathe which has been developed by the Montreal Foundry & Machine Co., Montreal, with the object of facilitating rapid construction combined with maximum production capacity. Every effort has been made to obtain ample rigidity, ease of manipulation and rapidity of production on shells up to 6 in. diameter. This machine has a height of 40 in. from the floor to the centre of spindle, a length of 10 ft. 6 in. and a width of 48 in., with an approximate weight of 14,000 lbs.



THREE-SPINDLE SHELL LATHE—ELEVATION.

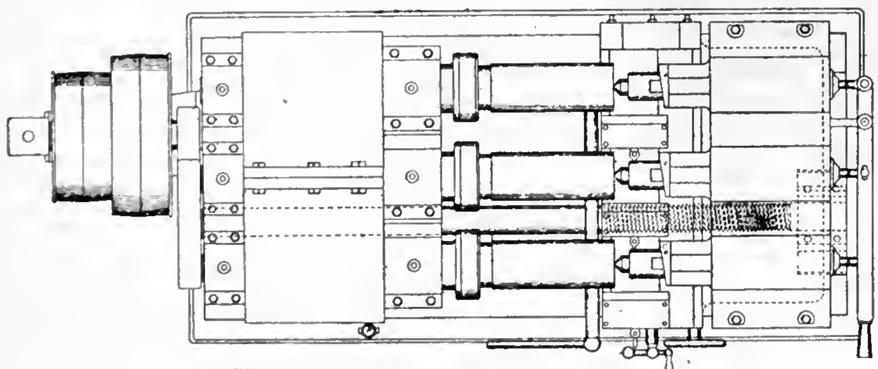
Four changes of spindle speed are provided, two from the counter shaft and two from the cone pulleys on the lathe. The three spindles are positively driven through a train of triple, semi-steel gearing: no idlers or frictions being used in the forward motion of the saddle. The return motion of the saddle, however, is accomplished by means of a friction clutch, located on the lead screw, below the headstock of the lathe. This clutch is operated by the lever, shown in front of the headstock. This lever also operates the quick change feeds. The arrangement of the mechanism is such that the change from one feed to another can be obtained while the lathe is in operation.

The drive is so arranged that the pulleys can be made to carry any width of belt suitable to the work for which the machine is constructed, the bracket being designed to suit the drive, which allows ample leeway for additional power. These machines can also be equipped with motor drive if required.

The main bearings for the spindle are made of bronze, with lengths of $7\frac{1}{2}$ and $5\frac{1}{2}$ inches, and diameters of $4\frac{3}{4}$ and $4\frac{1}{4}$ inches, for front and rear respectively. Each spindle is fitted with a special expanding driving chuck, which operates on the bore of the shell.

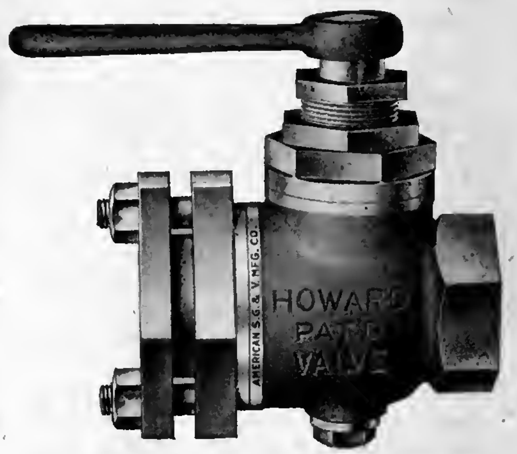
The tail stock is arranged so that the three centres can be operated rapidly and simultaneously, the design allowing for a variation of about $\frac{1}{4}$ inch in length in the work.

The carriage is of heavy design with a bearing length of 32 in., the front support so designed that the resultant thrust of the three operating tools comes at right angles to the direction of the thrust, thus reducing to a minimum any possibility of the saddle lifting. The carriage travel is obtained from the heavy coarse pitch buttress thread, lead screw L, located between the shears of the lathe and in a position as near as possible to the centre of the load, insuring a steady drive, and eliminating any undue strain upon the apron gearing.



THREE-SPINDLE SHELL LATHE—PLAN.

The driving nut is placed at the rear of the carriage, which prevents any cuttings falling on the lead screw thread. For traverse feeding by hand, the carriage is operated by means of the hand wheel which is connected by shafts and bevel gearing to the lead screw nut. The three tool posts can be adjusted separately to depth of cut, and operated simultaneously. If, at any time, it is necessary, through soft tools, hard shells, or other causes, a particular tool can be drawn back without stopping the whole machine, thus preventing unnecessary loss. Each tool post is of duplex type, or if desired any number of tools may be employed.



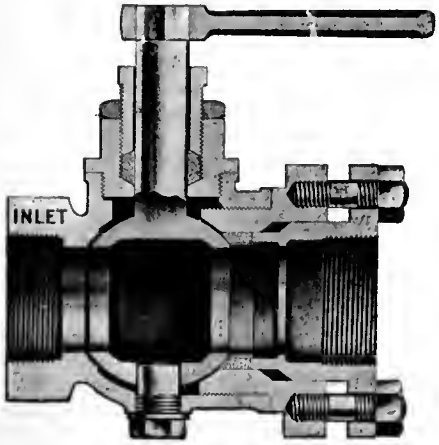
EXTERIOR VIEW OF BALL BLOW-OFF VALVE

IMPROVED BALL BLOW-OFF VALVE

AN improved Howard ball blow-off valve is shown in the accompanying cuts, being now manufactured by the American Steam Gauge & Valve Mfg. Co., Boston who have recently taken over its production and sale from the Howard Iron Works.

In its improved form the valve is provided with a one-piece ball and stem which completely overcomes former trouble with inserted stems becoming detached from the ball valve. Another improvement is the addition of a guide pin at the lower side of valve which retains the valve in position against the Bakelite packing. This maintains the stem in correct alignment with the stuffing box, while the packing material now

adopted possesses peculiar properties in regard to the surface of the ball, which keep the bearing surface smooth, polished, and in a state of maximum efficiency with little or no wear. A lock nut is also



SECTIONAL VIEW OF VALVE SHOWING IMPROVED CONSTRUCTION

provided to prevent unintentional slackening of the stuffing box gland on the valve stem during use.

THE TOOL-ROOM AND ITS EQUIPMENT

THE necessity for the establishment of a separate tool room as an adjunct to the machine shop is not always apparent, but all who are familiar with the methods of production demanded by modern conditions know that the tool room is an important unit in any manufacturing scheme, and that on its efficiency the profitable running of a plant is to a large extent dependent.

If the plant is composed purely of general purpose machines, such as engine lathes, drilling machines, planers, shapers, and slotters, the small tools and accessories which are required will consist almost entirely of standard articles like drills, taps, and reamers. These can be bought out, and, if supplemented by the necessary quantity of ordinary tools made by the blacksmith, will enable such a plant to be run with a fair measure of success.

A small tool equipment of this kind requires only to be kept in good working order and to be added to as occasion demands. In such cases, therefore, the work of the tool room is confined to storing the various small tools and accessories which are used in the machine shop, sharpening twist drills, cutting tools, etc., and attending to their distribution and collection.

It is obvious that work of this kind cannot be done properly unless a separate department—a tool stores rather than a tool room—is provided where it may be carried on without interference. In addition to the necessary storage racks and shelves the department should be equipped with the various machines—twist drill grinder, and wet tool grinder—which are used for maintaining the different cutting tools in good condition.

A machine shop as above described, in which the plant consists of general purpose machines, and provided with a tool store, may be quite efficient for repair or experimental work, but cannot undertake any real manufacturing with much hope of success when called upon to compete with others possessing a more suitable equipment.

To-day, every engineering establishment which aspires to be something more than an experimental or repair shop, includes in its plant a certain number of labour saving machines such as capstan and turret lathes, milling machines, and automatic screw machines. Machines of this kind cannot be run efficiently unless facilities are provided for supplying the special tools, jigs, and fixtures which they use. It is therefore essential that a tool room should be installed, having the plant necessary for the actual production of these articles, in addition to the accommodation and machinery which is required for their storage and maintenance.

Tool Room a Manufacturing Necessity

It may be argued that, provided plenty of spare cutters are ordered with the machines, a tool room, as distinct from a tool store, can be dispensed with; this assumption always proves to be a fallacy however attractive it may be to those who have to provide the money for purchasing plant. It frequently happens that, when machines are supplied, equipped with special tools for certain work, cutter breakages occur, due to careless handling, after they have been started up. The cutters are generally special so that the makers can hardly be expected to furnish replacements as quickly as the customer would like. The result is that, if the customer has no facilities for making the cutters himself, the machines stand idle, which is an unsatisfactory state of affairs for all concerned. Had the customer possessed a tool room the cutters could probably have been replaced without delay. The possibility of having high productive machines rendered unproductive or inefficient through lack of proper tools is in itself sufficient argument in favour of the provision of a tool room, which should be made one of the first considerations instead of the last. It is always advisable to be independent of outside supplies for, however carefully the probable demand is estimated and provided for, an unexpected sequence of accidents may cause some particular cutter to run out to stock.

Equipment Feature

We may now proceed to enumerate the machines with which a tool room should b equipped. It will be obvious that no hard and fast rules can be laid down, as the ideal equipment of a tool room cannot be the same in every case, but will be influenced by the character of the plant for which it has to cater. The entire subject is treated in an elementary manner, as will be noted, the intention being to offer suggestions to those who have not yet installed a tool room.

A convenient method of dealing with the question of what machines to instal will be to draw up a list of those which may be looked upon as essentials, indicating, in the less obvious cases, the kind of work on which they would be

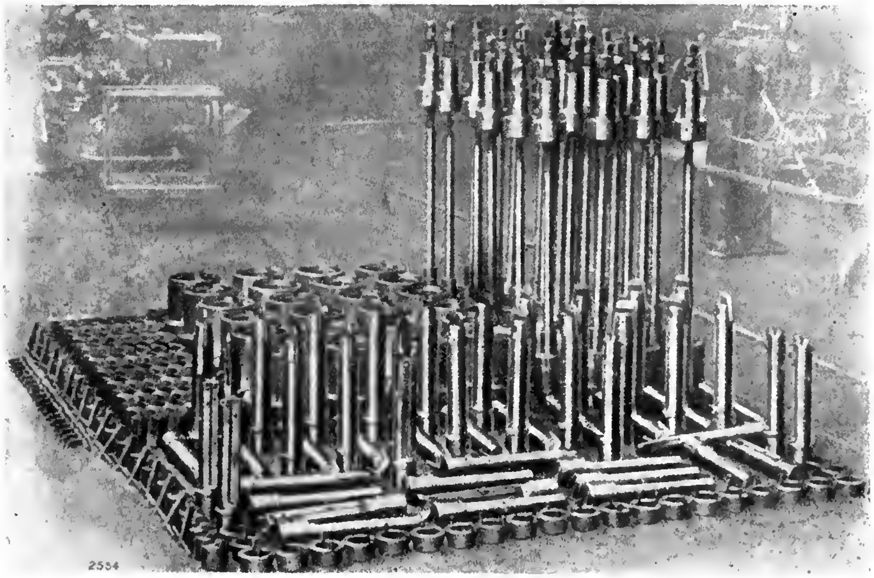


FIG. 1. SPECIAL TOOLS AND CHUCKS FOR BORING 60-PDR. HIGH EXPLOSIVE SHELLS ON ALFRED HERBERT NO. 3 HEXAGONT TURRET LATHES.

employed. The list is by no means exhaustive, but forms a nucleus which may be added to and modified as conditions demand.

1—A power hack saw for cutting off high speed steel bars. High speed steel is too expensive to permit the employment of any method of cutting off which involves the use of a wide cutter. Mild steel pieces may be requisitioned from the general cutting off department.

2.—A tool room lathe, say 7-in. centres, fitted with draw-in chuck, three-jaw and four-jaw chucks, taper attachment: a metric thread cutting attachment is also often very useful. This machine is used for making taps, dies, gauges, form-relieved milling cutters, and for all accurate turning.

4.—A gap lathe of good sturdy design about 9 in. centres, for rough turning boring bars, tool holders and milling boring bars, tool holders and milling cutters; also for occasional jobs requiring the large swing provided by the gap.

5.—A precision bench lathe with the usual attachments, including screw cutting; used for making small taps, dies and gauges.

6.—A universal milling machine, say 20-in. x 7-in. x 18-in. having automatic feeds in all directions, vertical milling attachment, and slotting attachment; for fluting milling cutters, reamers, special drills, cutting slots and keyways, and jig boring.

7.—A 6-in. slotting machine with circular table. If this machine is installed, the slotting attachment under item 6 can be omitted.

8.—A two spindle ball bearing drilling small machine with one geared spindle for drilling small holes, counterboring and facing.

9.—A heavy upright drilling machine, say 25-in. swing, with compound table; for large jig work.

10.—An 18-in. double geared shaper for roughing out form tools, tool holders and cutter blades.

11.—A 12-in. x 36-in. Universal grinding machine for all external and internal cylindrical work.

12.—A universal tool and cutter grinded with full complement of attachments, with the exception of those for external and internal grinding which are covered by Item 11.

13.—A surface grinder, for form tools, boring cutters and gauges; not perhaps required unless a large amount of surface grinding has to be done; otherwise this work is covered by Item 12.

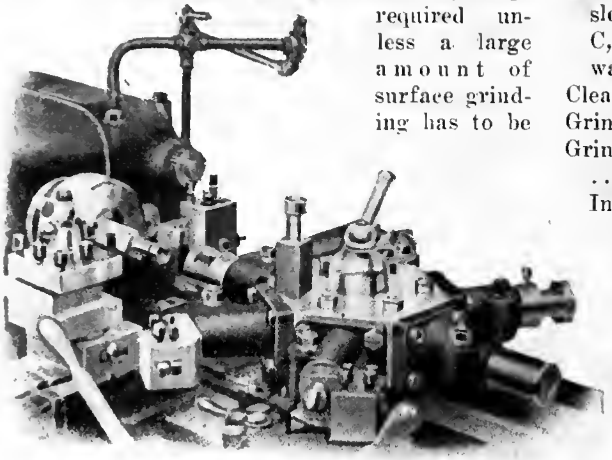

FIG. 2. TYPICAL OUTFIT OF CAPSTAN LATHE TOOLS.

14.—An oscillating tool grinder for making all kinds of lathe, planer, and shaper tools; also for roughing out form tools.

15.—A wet tool grinder for sharpening lathe tools and similar work.

16.—A twist drill grinder.

17.—A marking out table.

18.—An arbor press.

19.—A hardening furnace for high speed steel. This may, in some cases, be more conveniently placed with other furnaces in the general hardening department

It will be noted that no mention has been made of measuring machines, reference discs for checking gauges, and other precision tools of the like nature. If the character of the work done in the main shop necessitates the employment of such tools they must be included in the tool room equipment.

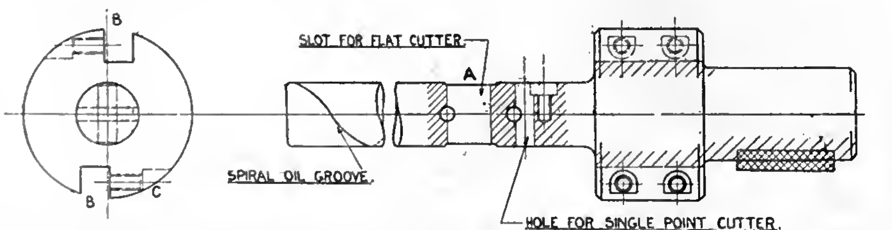

FIG. 3. BORING BAR FOR USE ON A CAPSTAN LATHE, HAVING SLOTS IN THE COLLAR FOR CARRYING TWO CUTTERS FOR COUNTERBORING OR END FACING

To show the utility of the machines included in the list, we will assume that the boring bar shown in Fig. 3 has to be made. The following is an outline of the operations, although not necessarily in the correct sequence, which would be required in producing this typical capstan lathe tool.

Operation.	**Machine Used**
Cut-off to length	Not in tool room
Centre the two ends	Item 2
Rough turn	Item 4
Mark out	Item 17
Drill and tap	Item 8
Mill slot A, flats on sides of slot A, slots B, counterbores C, spiral oil groove, and keyway	Item 6
Clean out corners of slot A	Item 7 or 6
Grind to finished size	Item 11
Grind flats on sides of slot A	Item 12 or 13

Indirectly, Items 15, 16, 18 and 19, are also used, thus bringing over 60 per cent. of the plant into operation on one piece of work. The remainder of the machines would nearly all be brought into use in providing the cutting tools. The list of machines given may at first sight seem a formidable one to those who are thinking of starting a tool room, but an examination will show that a large number of them are standard machine tools.

It does not follow that because a tool room is available it is advisable to make in it all the tools which are required by the shop; it is frequently more economical to buy the majority of these from firms who specialise in their manufacture. Standard twist drills, taps, reamers, and box tools must obviously be purchased from outside, leaving the tool room free to deal with special tools, jigs, and fixtures. Work of this kind should be brought into the proper department instead of being allowed to drift through the works impeding the regular output. If there happen to be, on large jigs or fixtures, some operation —planing for instance—which is outside the possibilities of the tool room plant, the machine shop may then come to the rescue; this should, however, be as far as possible avoided.

Whether a special drawing office staff is required depends entirely on the amount of tool work and on its character. Where replacements only have to be dealt with or new tools of a simple nature, all the necessary designing can in most cases be left to the foreman tool maker. Where new layouts of tools have to be made for the more complicated work of automatic screw machines and the like, a draughtsman is essential, for clearances are frequently cut fine, and alterations found necessary by trial are expensive to rectify.—Herberts' Monthly.

B. E. Barnhill, for many years divisional engineer on the Algoma Eastern Railway, has been appointed to a similar position with the Algoma Steel Corporation, Sault Ste. Marie, Ont.

THE INTERCHANGE OF DATA

THE subject of industrial research is receiving very considerable attention as a result of its influence on the development of the manufacture of certain products of vital importance to various branches of industry in different parts of the world.

That the co-ordination of effort in this direction is desirable from a national point of view goes without saying, but in all of the schemes and proposals now being advanced, and efforts being made, to give the subject due attention, a point arises, regarding which all future developments of the subject will take issue as being for or against.

The general impression of the man in the street seems to be that the results to be obtained by industrial research as a feature of future manufacturing activity will be a sort of panacea for our past troubles, and a reinforcement of our future efforts to maintain our position amongst the producing nations of the world. References are frequently made to the subject in a broad, sweeping manner, but always with a vagueness indicative of the wish being father to the thought, rather than being based on definite knowledge and experience.

As a matter of fact there is little or no mystery in the situation whatever. The lines along which industrial research must be carried on will be decided by manufacturers themselves, for however generously inclined a Government or administrative body might wish to be, it cannot be doubted but that little advantage is to be gained by publishing results broadcast to the world. The element of secrecy has been and always will be to some extent a factor in many industries which are not purely mechanical. Machinists' activities are always disclosed by results. Every piece of apparatus, equipment, jigs, tools, measuring instruments and methods are each the result of known principles, based on fixed mechanical laws, the value of which varies, however, with the ingenuity of application. They are concrete in form, and their action is visible to, and capable of comprehension by comparatively untrained minds. Just as soon, however, as the problem reaches phases which do not involve the use of mechanical appliances, and enters the regions of electricity, thermodynamics and chemistry, the field for research broadens out instantly.

The science of the conversion of heat into mechanical energy is equally well developed and understood in most countries; the broad principles of chemistry are being more widely known every year, and electricity is almost commonplace in its applications, yet it is not to the multitudes engaged in making or using these things that the world is indebted, although it more frequently rewards them.

The men to whom the world is indebted are the engine designer, naval architect, chemical manufacturer, metal producer—in a word, the men who perceive the applications of abstract knowledge to concrete results, who place processes and materials at the disposal of the engineer whereby work may be done for the benefit of mankind—more of it, better and cheaper.

The results of industrial research are the well from which civilization has sprung and while the humble machinist in performing his daily labor is a necessary factor in the distribution of such results, it does not follow that widespread research would benefit him individually. The full value of research is in its influence on one or other particular industry and under present conditions, limits those influences to certain countries. The day of broadcast industrial knowledge is still far distant. An exemplification of this is evidenced by the attitude of British engineers relative to the interchanges of data and ideas regarding the development of the Diesel engine, a peculiar reluctance to enter any discussion whatsoever of the subject being recently displayed by men who are known to be in possession of information regarding the design of this type of prime mover, the growing importance of which is commanding attention from engineers of all nationalities.

We feel, however, that circumstances, past and present, justify a closer surveillance of technical knowledge of this nature, and confidence in our manufacturers throughout the Empire at this time may well be worth while in anticipation of the advances that will materialize at a later date and concerning which we little reckon at the present moment.

CANADIAN SHIPBUILDING

THE launch of the icebreaker "J. D. Hazen," on May 15, from the yard of Canadian Vickers, Montreal, marks a new era in the development of shipbuilding and marine engineering within the confines of the Dominion of Canada. The event, as was to be expected, created unusual interest among citizens of all classes in our Canadian Metropolis, although to the commercial and manufacturing community the import of the occasion carried an even deeper significance.

Following closely on the eloquent plea made a few weeks ago by Col. Cantley, president of the Nova Scotia Steel & Coal Co., for systematic and effective Government recognition of the Canadian shipbuilding industry, particularly on our ocean waterways and ocean shores, and being graced by the presence of many members of the Federal Cabinet, including the Prime Minister, there is little doubt but that the above function will give the additional and perhaps just the remaining stimulus necessary to put steel shipbuilding on a basis whereby it may both meantime meet competition from outside, and ultimately become self-supporting as has our steel industry.

Canadian Vickers, in their administrative, management and constructional organizations are to be congratulated on the achievement of building the "J. D. Hazen," and we may be pardoned for prophesying that each succeeding year will see others like her, together with those of a more strictly commercial type maintain and enhance the now established reputation.

SELECTED MARKET QUOTATIONS

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, May 15, 1916.—The scarcity of labor continues to be a serious question, and this will become more pronounced as the good weather approaches. The carters' strike has been settled, the men accepting an increase of 10 cents per day. This will result in some relief to the freight situation, as the various roads were compelled to place a temporary embargo on goods coming to Montreal.

Pig Iron

Little can be said regarding the pig iron situation, with the exception that foundry iron is very quiet, and the capacity of the furnaces is being taxed to supply the requirements of the steel-making industries.

Steel

Inquiry and demand for shell steel, both for home and export, continues very heavy, and the fact that much of this supply is to be delivered before the end of the year indicates that the capacity of some of the mills must be very elastic, as it was generally supposed that this year's output of many of these large mills had been booked months ago.

Few price changes are noted this week; certain interests have added $1 to $2 per ton on light black sheets. Plate mills are still unable to book orders under two or three months' delivery, and those who are in a position to run off small tonnage between their contracted output are able to demand a good premium. Blue annealed and deep drawing sheets are still in great demand, with mills unable to supply the requirements of the trade. Wire and wire products are very active, but the high prices are affecting domestic consumption, with the result that many mills are taking on additional export business. Boiler tubes are in exceptionally heavy demand, with the probability of further advances on present price lists.

Metals

The general tone of the market is one of exceptional quietness. Little activity is shown in any of the metals, and prices are inclined to be easier. The position in copper is very uncertain, and some large orders which were supposed to be pending have not materialized. Consumers of tin appear to be well covered at present, and the market is weaker. The supply of spelter, coupled with poor demand, has resulted in reduced prices. Lead is very dull, but the market is firm on a better outlook. The recent arrivals of antimony have exceeded the demand, and a weaker market has developed.

Copper.—The situation at present is rather peculiar in respect to buying and selling of metal. Reports are current that prompt and nearby metal is required, while on the contrary sellers in some instances appear unable to dispose of copper on hand. Under these conditions the market is hard to define. However, while the present market is quiet, there is further inquiry for export metal, but closed orders have not yet been recorded. London reports a strong market on advancing prices; this week's quotation shows an advance of £4 on standard and electro spot, and £5 on standard futures. Current prices are £141 for spot and £135 for future standard, with electro quoted at £154. New York is firm, with the exception of electrolytic, which has declined ½c, present price being 30½c. Local conditions are unchanged, with prices firm.

Tin.—The market is dull, with comparatively little business being done. In the absence of spot metal, ten days' delivery is offered at slightly shaded prices on the nominal figure. The general tone is easier, and further decline may be looked for, but owing to lack of definite information it is difficult to state to what extent the reaction will extend. When buyers become attracted by the declining prices, the effect will be to again strengthen the market.

The London market has weakened, and quotations have declined £3 on standard spot and £2 on futures, with a drop of £3 on spot Straits, the present prices being £198, £197 15s. and £198 respectively.

Following a dull market, New York is quoting 49c, a decline on the week of 1½c per pound. Dealers here are asking 49c on a quiet market.

Spelter.—Reports from dealers indicate a very quiet market, and, while export demand is fair, the inquiry for domestic requirements is comparatively light. The needs of the brass producers, and also the galvanizers, are not very heavy, as is evidenced by the fitful buying of these interests. London prices are firm, while New York has declined ¾c per pound, nominal quotation being 16.8 per pound. The general situation elsewhere is reflected here by a quiet market on declining quotations, present price of 21½ indicating a drop of ½c on the week.

Lead—The market is quiet, with an undertone of increasing activity, owing to a better demand from foreign sources. While prices are unchanged, the situation seems brighter, as dealings in lead are showing a little more life, following a period of relative dullness. London reports a good market with higher prices, an advance of 2s. 6d. bringing spot up to £34 5s., and a 5s. advance on futures makes the current price £34.

New York is quiet, with prices firm, and dealers here report unchanged conditions, with quotations firm at 9½c per pound.

Antimony.—A plentiful supply of both American and Eastern antimony has created the tendency of holders to unload, fearing a further decline. Any excessive selling movement on the present market would result in a still further decline. The possibilities are that the market will become steadier in a short time. A decline of 2½c leaves the New York quotation at 35c per pound. Dealers here report a very quiet market on a decline of 1c, this week's price being 44c.

Aluminum.—With the exception of some heavy Russian buying, the market is unchanged and prices are firm at 68c per pound.

Machine Tools and Supplies

Recent disturbances, affecting the machine tool industry throughout the East and Central States, have somewhat subsided, and conditions are gradually righting themselves, and, while certain trades are still inconvenienced to some extent, the general situation is constantly improving. It is anticipated that any dissatisfaction now existing will be shortly adjusted, with possibly a few exceptions. Many of the shut-downs reported last week in the Pittsburg district have been settled by the men voluntary returning to work. The demand for machine tools in the meantime is comparatively quiet, but builders are still kept busy filling long-placed orders. Inquiries for special equipment is fair, and domestic demand is good. The recent decision of the Government regarding their policy toward railway interests is expected to result in additional equipment for railway purposes. A steady demand continues for all supplies, and prices are constantly advancing.

Old Materials

The majority of scrap metals have been fairly active, and considerable business is reported by dealers in heavy melting steel scrap and old copper. Old lead is easier, and the poor demand for scrap zinc has lowered prices. All coppers are quoted ¼c easier, and quotations range from 18c for light to 21¾c for heavy. No. 1 composition turnings show a decline of ¼c, being quoted at 14¾c per pound. With a reduction of ½c, scrap zinc is now 14½c.

Toronto, May 16. — There is little change to note in the industrial situation. The volume of business generally is increasing steadily and the outlook is satisfactory. War orders are keeping our industrial plants operating at capacity and indications point to continued activity for a considerable time thus enabling the companies concerned to accumulate sufficient reserves of capital to put them in good shape and permit of expansion when desirable. The expenditure on munitions is much greater than in any other industry and consequently the machine shops and engineering plants generally are benefiting in a proportionate degree. These departments are exceedingly prosperous and were never in better shape either financially or in the efficiency of the various plants making munitions or machine tools for their manufacture. The motor car trade is also very prosperous, the sales so far this season being far ahead of the corresponding period last year.

The tendency for higher prices is still in evidence and there is no indication at present of any halt in the upward movement. Raw materials are becoming more difficult to obtain and the shortage of labour is also affecting the situation very materially. Manufacturers are therefore seriously handicapped and their output is being considerably curtailed. The freight situation has improved following the settlement of the teamster's strike in Montreal and the opening of navigation. The movement of goods both to the East and West is heavier and the congestion in the railway yards is gradually being relieved. Railway earnings are showing big gains indicating a considerable increase in the volume of freight being moved.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel Market

The situation in the steel trade is generally much the same as last week. Prices have still an upward tendency although the market is steadier and changes are less frequent than formerly. The shortage of steel is more pronounced and there is little hope of any improvement this year as the mills are booked up until the first quarter of 1917 and they are getting further behind on deliveries. The export demand continues heavy and would absorb practically the entire outlet of the mills if the steel companies were in favor of this policy. The demand however for steel for shells is also very heavy and must take precedence over other business.

The advances this week include 25c on boiler and structural rivets, making the new prices $4.85 and $4.75 per 100 lbs., respectively. Pressed steel spikes ⅝ diam., are up 15c, and are now quoted at $3.90 per 100 lbs. A new discount of 25 per cent. on iron plate washers has been announced. Prices on wrought iron pipe are very strong and it is intimated that they will be higher in the near future. Most manufacturers are unwilling to quote on pipe for extensive undertakings because of the uncertainty of the future situation for skelp which is both scarce and high in price. The demand for boiler tubes is very heavy in the primary market and deliveries are now running into the fourth quarter. Prices are strong and are likely to be higher within a short time. The market for cold rolled shafting is also very strong and higher prices are looked for in the near future. All shafting makers have their output sold up practically through the third quarter, and have taken contracts for delivery in the fourth quarter. Prices of all wire products are very firm at the recent advance and higher prices on some lines, particularly wire nails are anticipated.

The sheet market is very firm and prices are unchanged. On blue annealed sheets the mills have very little to offer for delivery inside of five or six months although deliveries on black sheets are not so backward. Some mills are operating only at part capacity as they are unable to get sufficient sheet bars. There is no improvement in the galvanized sheet situation some mills are operating their galvanizing departments at only about 25 per cent. capacity. Prices on galvanized sheets are firm and unchanged.

Heavy contracts are still being placed in the United States for steel by the

Allies and the mills continue operating at capacity. The unfilled tonnage of the United States Corporation for April totalled 9,829,551 tons being an increase of 498,550 tons over the previous month March. The market is much steadier and there is a decided sentiment against a further advance in prices of finished materials. Prices are however very firm, steel bars being quoted at 3c; plates 3.75c, and shapes 2.60c, f.o.b. Pittsburgh. A leading railroad in the U.S. recently placed an order for 1000 wooden underframe box cars with the American Car & Foundry Co. This is a phase of the steel situation which is of considerable significance.

Old Materials

The market is quiet, and prices are generally unchanged although firm for most scrap materials with the exception of lead and zinc which are weaker. Wrought iron pipe is higher and is now quoted at $10; being the only change of any particular importance to note.

Machine Tools

The market is steady with a fair demand for tools for munition plants principally for single purpose lathes for machining the larger calibre shells. Delivery on this class of equipment is good but standard tools particularly millers, planers and grinders are hard to get inside four to five months. The Grand Trunk Railroad is in the market for considerable number of tools for the various repair shops throughout the system. The list includes lathes, drill presses, slotters, shapers and planers, etc.

Supplies

Prices of machine shop supplies continue to advance and further changes have been made during the week, Malleable and cast iron pipe fittings have advanced about 5 per cent. A new list of discounts on carbon drills and reamers has been issued, standard drills up to 1½ in. being now 45 per cent. Leather belting has advanced the new discount on extra heavy being 40 per cent. as against 40 and 10 per cent. formerly. Both linseed oil and turpentine are weaker and lower prices are being quoted. Turpentine is now 70c per gallon while linseed oil is 89c for raw and 92c for boiled oil. Starrett's mechanics tools have recently been adjusted in price to cover an increase of about 10 per cent.

Metal Markets

The copper market continues strong and the situation interesting. Prices are unchanged for all metals with the exception of antimony which is lower. The tin market is steadier with a firmer undertone. The lead market which was weak has recovered and the outside market is a shade higher this week although the 'Trust' price is unchanged Spelter is very weak with little business doing. Aluminum is unchanged and the market featureless.

Copper.—A good demand for copper is still in evidence both for export and domestic consumption. So far as the big producers are concerned there is now no metal available for sale before September. Heavy sales of September delivery are reported from New York at 29c per lb., and the fact that there is but a limited quantity of September copper left, indicates an early advance in this position. Quotations in London have advanced far beyond previous records and are still tending upwards. The local market is firm and unchanged at 32c per pound.

Tin.—There is a better feeling in the market as it is anticipated that shipments of tin will come forward from England in better volume that has hitherto been the case. Prices have been declining steadily, chiefly on spot tin, owing to lack of demand but there is now a firmer feeling and the market is steadier and unchanged at 54c per pound.

Spelter. — The market is dull and weak. A lack of demand from brass producers is in evidence as well as only hand-to-mouth buying by the galvanizers. The local market is weak and unchanged at 22c per pound.

Lead.—The situation in the lead market has improved considerably in New York on account of an increase in the export demand. The outside market has recovered and is higher, but the "Trust" is unchanged at 7.50c, New York. The local market is firmer and unchanged at 9½c per pound.

Antimony.—The continued lack of demand for antimony has caused prices to sag and the market is unsettled. Local prices are lower and nominal at 45c per pound.

Aluminum. — The demand continues dull and the market featureless. Quotations are unchanged and nominal at 60c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

CANADIAN RAILWAY CLUB ANNUAL

THE fourteenth annual meeting of the Canadian Railway Club took place on Tuesday evening last at the Windsor, Montreal. R. M. Hannaford occupying the chair. The secretary's report went to show that the past year had been a fairly good one. Allusion was made to the fact that the president, L. O. Ord, had enlisted and gone overseas, his place being filled by R. M. Hannaford, first vice-president. Some twenty-three of the members had gone to serve their King and country, and two of them, Messrs, W. C. Rutherford and L. Curry, had fallen on the field of honor. The following officials were elected, the president being re-elected.

President R. M. Hannaford, assistant chief engineer, Montreal Tramways Co., Montreal; first vice-president, G. E. Smart, master car builder, Canadian Government Railways, Moncton, N.B.; second vice-president, Prof. Keay, professor railway transportation, McGill University, Montreal. Executive committee—Messrs. T. C. Hudson, master mechanic, Canadian Northern Quebec Ry., Joliette, Que.; E. E. Lloyd, auditor of stores and mechanical accounts, Canadian Pacific Ry., Montreal; J. Hendry, master car builder, Grand Trunk Ry., Montreal; C. Manning, secretary to superintendent of motive power, G.T.R., Montreal; C. W. Van Buren, general master car builder, C.P.R., Montreal; W. H. Winterrowd, assistant to chief mechanical engineer, C.P.R., Montreal. Audit committee—Messrs. F. A. Purdy, Canadian manager, Chicago Car Heating Company, Montreal; A. Crumpton, assistant valuation engineer, G.T.R. Montreal; A. G. Mitchel, chief clerk, office of master car builder, G.T.R. Montreal. Secretary, James Powell, chief draughtsman, motive power department, G.T.R., Montreal. Treasurer, W. H. Stewart, assistant superintendent, C.P.R., temporarily with the Imperial Munitions Board, Ottawa.

WELLAND SHIP CANAL PROGRESS

THAT, notwithstanding the war, most satisfactory progress has been made on the four sections of the Welland ship canal which have already been contracted for, and that three at least of these sections will be finished within the four-year schedule, the work having been

started in 1913, was the statement of Chief Engineer J. L. Weller, who planned and is in charge of this undertaking, which will cost Canada $60,000,000 or $70,000,000. Fifty per cent. of the contracts on Nos. 1 and 2 sections are completed.

On No. 3 section, at Thorold, which is the largest section, having three double locks, and which contract costs the sum of $10,000,000, only about 25 per cent. of the work is finished. This section, Mr. Weller says, will not be finished on schedule time, but will run along into 1918 at least. The work there is proving very heavy, it being necessary to blast through the solid rock down 80 feet. The blasting is about finished for the first pair of locks, which will be bigger than those of the Panama Canal. It was on this section that the strike occurred recently, but the majority of the men are back at work.

Section 4, between Allanburg and Thorold, has not yet been let, but section 5, at Allanburg, is half completed.

MAKING FRENCH HELMETS

IN turning out one of the plain steel helmets worn by French soldiers, 64 distinct operations are necessary. The first step in stamping out discs from large sheets of steel, a special machine being used for the purpose, exerting a pressure of 150 tons, and capable of cutting out 5,000 steel discs a day. Each disc is placed under a shaping machine, which presses the disc into the form of a helmet with a broad rim. Polishing and cutting machines remove all irregularities in the helmet, after which holes are punched in the crown, some for ventilation purposes, others for fastening on the regimental crest. Each helmet is cleaned and dipped in a special mixture, which makes it a dull, inconspicuous bluish gray. A lining and leather chin strap are then fastened on, and the helmet is complete. Since the French army has been protected with the helmet, the number of deaths due to wounds in the head has decreased to a remarkable extent.

Electro-Platers' Convention.—The Annual Convention of the American Electro-Platers' Society, which was to have been held at Toronto, Ont., this year, will on account of the war, be held in Cleveland, instead, with headquarters at the Hotel Statler, on July 6, 7 and 8. A large number of interesting papers on plating and non-ferrous metallurgy will be presented. The Cleveland branch of the society is arranging a suitable entertainment program.

New Trade Commission.—The following have been named as the commission of six Canadians who will go to Europe to examine opportunities for the extension of Canadian trade among the allied nations: James W. Woods, Toronto; Theo. H. Wardlworth and Frank Pauze, Montreal; H. Edmond Dupre, Quebec; W. Frank Hatheway, St. John, and George W. Allan, Winnipeg. The commissioners will proceed to Europe shortly and they will visit Great Britain, France, Belgium and Italy.

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Winnipeg, Man.—The Breen Motor Co. will build a garage on Broadway, 116 ft. by 50 ft.

Montreal, Que.—Darling Bros., engineers, are building a $30,000 addition to their factory.

Simcoe, Ont. — Lampman's Pump Works on Peel street, were totally destroyed by fire on May 11.

Farnham, Que.—The Dominion Safe & Vault Co., are removing their plant to Niagara Falls, Ont.

Niagara-on-the-Lake, Ont.—It is proposed to install electrically driven pumps in the water works plant here.

Hamilton, Ont.—The Hamilton Bridge Works, will build a steel and concrete addition to its plant at a cost of $7,500.

Renfrew, Ont.—The Renfrew Machinery Co., will have work commenced at once on the erection of a factory to cost $8,000.

Vancouver, B.C.—Efforts are being made by the Chamber of Mines to secure the establishment of an iron smelter near here.

Mount Forest, Ont.—J. R. Baird, is in the market for an air compressor, complete with motor or gasoline engine for a garage.

Three Rivers, Que.—The Wayagamack Pulp & Paper Co., will build an extension to their paper mill here to cost about $11,000.

Meaford, Ont.—The Meaford Wheelbarrow Co., is in the market for a tinsmith's brake 6 ft. long, to bend 16-gage sheet iron.

Toronto, Ont.—The Martin Pump & Machine Co. propose erecting a factory at Wilton and Broadview avenues, estimated to cost $10,000.

Timmins, Ont.—The Hollinger Gold Mines, are building an addition to their mill, estimated to cost $750,000. Mining machinery will be required.

Toronto, Ont.—The Wilson Munitions have taken out a permit for a one-storey brick moulding shop in 438 Dufferin street to cost $1800.

Berlin, Ont.—The Consolidated Felt Co., is in the market for a hydraulic pump of 2000 lb. per sq. in. pressure for a 16-in. diameter cylinder press.

Glenwood, Ont.—The Dominion Natural Gas Co. will probably install a duplicate gas purification plant here. Mr. Thom is manager of the company.

Redcliffe, Alta.—The Canadian Western Steel Co., which recently purchased the Redcliffe Rolling Mill, will establish a plant here for making nuts and bolts.

Galt, Ont.—The Goldie & McCulloch Co., manufacturer of boilers, condensers, etc., will commence at once the erection of an addition to its plant to cost $100,000.

Berlin, Ont.—Bids will soon be asked on large addition to the boiler house and plant of the Gas & Electric Co., Gaukel street, Mr. McIntyre is superintendent of the plant.

Timmins, Ont.—The Hollinger Gold Mines will shortly start work on an addition to their mill. Estimated cost, $750,000. Secretary-treasurer, David A. Dunlap, 85 Bay Street, Toronto.

Montreal, Que.—W. Duquette, has received a permit for the erection of a reinforced concrete, four-story garage to be constructed at the corner of Laurier Avenue and Durocher Street, Outremont, at a cost of $50,000.

Montreal, Que.—J. D. Lachapelle & Co., engineers, Montreal, are laying out and doing the purchasing of electrical equipment for the new plant which is being installed at Montmagny, Que., for the General Car & Machinery Co.

Toronto, Ont.—T. A. Russell, representing the Russell Motor Co., has made application to the York Township Council for a fixed assessment for 20 years on 30 acres of land and a factory, which it is proposed to build near Weston. The first cost of the buildings will be $100,000.

G. T. R. BUYING MACHINE TOOLS

The Grand Trunk Railway is in the market for machine tools for the various repair shops throughout the system, embracing Battle Creek, Mich.; Pontiac, Mich.; Stratford, Ont.; Allandale, Ont.; Island Pond, Vt.; Toronto, Ont., and Montreal, Que. The equipment required includes drill presses, lathes, millers, planers, shapers, slotters, flanging presses, etc. Full particulars may be obtained from G. W. Caye, general purchasing agent, G. T. R. offices. McGill Street, Montreal.

SAW-MILL MACHINERY REQUIRED IN RUSSIA

Makers of saw-mill machinery will learn with interest that Russia now occupies first place among the nations of the world in the extent of its timber resources. The total area of the Empire is about one-seventh of the land surface of the globe, and 39 per cent. if it is under forests.. Those in European Russia cover an area of 474,000,000 acres; in Finland, 50,500,000 acres; in Poland, 6,700,000 acres; and in Caucasus 18,600,000 acres; a total of 549,800,000 acres, exclusive of Siberia. The Russian Forestry Department places the total timber land in Siberia at 810,000,000 acres, of which two-thirds can be successfully placed on the market.

Electrical

Fredericton, N.B.—The city council contemplate installing a modern fire alarm system.

St. Foye, Que.—The town council are considering the installation of an electric lighting system, estimated to cost $15,000.

Stratford, Ont.—The town council are considering extensions and improvements to the electrical system, estimated to cost $33,000.

Toronto, Ont. — The Scarborough township council have opened negotiations regarding the lighting of the Kingston Road, Scarborough Junction and Agincourt.

Uxbridge, Ont.—The Hydro Commission have written the town clerk stating that an engineer would be in Uxbridge in the near future to report on the possibility of furnishing the town with electric power.

Welland, Ont.—The Stamford council has approved of the purchase of the Ontario Distributing Co. system. A bond issue for $30,000 will be raised to cover the cost of the transaction, part of the money to be used to cover the cost of extensions to the distributing system.

Municipal

Elmira, Ont.—It is proposed to loan $15,000 to the Colonial Knitting Co.

Vancouver, B.C.—The City Council are in the market for a centrifugal pump and motor.

Sutherland, Sask.—An expenditure of $36,000 on waterworks and street improvements is contemplated.

Stratford, Ont.—A bylaw will be voted on to provide $30,000 for improvements to electric distribution plant.

Dundas, Ont.—The by-law to provide $55,995 for the construction of sewage disposal works, etc., has been defeated by the ratepayers.

Sherbrooke, Que.—It is proposed to spend $300,000 on the development of power at Westbury Basin. A by-law will be submitted on June 19.

Elmira, Ont.—The ratepayers on May 9 voted in favor of a by-law to grant a loan of $6,000 to the Ardiel Shoe Co. Two other industrial by-laws are to be voted on next week. The Ardiel Co. is in operation here now, but will extend the plant with the $6,000 afforded them by the by-law.

St. Catharines, Ont.—The City Council has passed a by-law to issue debentures to the amount of $84,000 for extensions to the hydro-electric system.

Hull, Que.—A by-law will be voted on by the ratepayers on May 22 to raise $146,000 for improvements to the waterworks, electric light and fire alarm system.

Preston, Ont.—A by-law to vote a loan to the Electrical Fittings & Foundry Co. was carried by a large majority on May 8. The new concern will occupy the large building that was erected for the Anchor Bedding Co., but which was never used.

QUEENSLAND GOVERNMENT RAILWAYS, BRISBANE

The following indent was recently despatched by the Queensland Government Railways, Brisbane, to the Agent-General for Queensland, Marble Hall, 410 The Strand, London, England:—

		Estimated Cost. £	s.	d.
1	set turbo generator set, 300 kilowatt capacity	3,800	0	0
2	centrifugal pumps, with motors complete	500	0	0
2	water tube boilers to supply turbo generator	4,000	0	0
1	coal and ash handling plant—steam driven	2,800	0	0
1	electrically driven two stage intercooled air compressor	1,500	0	0
1	switchboard, instruments, etc.	600	0	0
1	one Pond wheel lathe, motor driven	1,800	0	0
1	two table 36-inch boring mill, belt driven	830	0	0
1	profile milling machine, motor driven	900	0	0
1	plain milling machine, belt driven	300	0	0
1	slotting machine, belt driven	200	0	0
1	slide bar grinding machine, belt driven	220	0	0
1	one 14-inch x 50-inch plain grinding machine, belt driven	400	0	0
1	one 4' 2" radius high speed, motor driven, radial boring tapping and studding machine	350	0	0
1	light drilling machine, belt driven	45	0	0
1	power hacksaw 6-inch, belt driven	50	0	0
1	24-inch heavy duty shaping machine, belt driven	145	0	0
1	12-inch surfacing and screw-cutting lathe, motor driven	400	0	0
1	Gridley automatic turret lathe, 2¼ bar size, motor driven	500	0	0
1	two head screwing machine, belt driven	250	0	0
1	one hydraulic crank pin press	125	0	0
1	Lumsden tool grinder (oscillating), belt driven	210	0	0
1	small 6-inch lathe for tool work, belt driven	120	0	0
1	universal milling machine, belt driven	200	0	0
1	tool hardening furnace and pyrometer, gas and air	50	0	0
1	15 cwt. hammer	600	0	0
1	10 cwt. steam hammer	500	0	0
2	"Acme" root blower, motor driven, complete for fifty fires	500	0	0
3	additional motors	300	0	0
1	40 ton overhead traversing girder crane, electric driven	2,000	0	0
1	automatic knife grinder, 30-inch	45	0	0
1	small jig saw	30	0	0
1	saw sharpening and gulloting machine, mill web or circular saw	30	0	0
1	emery grinder for general tool work	20	0	0
1	double spindle shaper, capacity 6" x 6" with grooved table for fixtures	60	0	0
1	chain mortising machine, with chain and grinding attachments	70	0	0
1	planing and smoothing machine, motor driven	250	0	0
1	moulding machine, 4 head capacity, 18" x 16" motor driven	375	0	0
1	horizontal square chisel mortiser, 18" x 18" timber with boring attach't., motor driven	325	0	0
1	heavy rip-saw, colonial type bench, 6' x 3' x 9", maximum, saw 48"—motor driven	150	0	0
1	small tenoning machine	60	0	0
1	wood-working machine with cutters, motor driven	400	0	0
	Additional cutters for machines	200	0	0
3	additional motors	640	0	0
	Total	£26,850	0	0

Campbellford, Ont.—A by-law will be submitted to the ratepayers on May 22 to authorize a loan of $30,000 to the Northumberland Paper & Electric Co.

Westport, Ont.—The ratepayers will vote on May 31 to give Westport Electric Light & Milling Co., a ten-year franchise for installing an electric lighting system.

Belleville, Ont.—The City Council is contemplating the making of a number of additions to the waterworks plant, including a new pump to be installed at the pumping station.

St. Thomas, Ont.—At a special meeting of the City Council on May 10, it was decided to issue debentures for the purpose of building a hydro-electric substation on St. Catharine Street.

Medicine Hat, Alta.—The City Council contemplate the construction of another pipe line from the waterworks plant to the city. The total cost will be about $25,000, including $16,000 for pipe.

General Industrial

Preston, Ont.—The Solid Leather Shoe Co., are building an addition to their factory.

Montreal, Que.—The Columbus Rubber Co., Maisonneuve, are making an extension to their factory.

Sackville, N.S.—The factory of the A. E. Wry Standard Co., which was destroyed by fire some months ago is being rebuilt.

Port Arthur, Ont.—It is reported that an industry is to be established in this neighborhood for the manufacture of pine tar products.

Camrose, Alta.—The elevator at New Norway near here belonging to Jas. Richardson & Son, of Calgary, was destroyed by fire recently. The loss is fully covered by insurance.

Sarnia, Ont.—The cost of building the new flax mill here, which is to commence shortly, is estimated at $15,000. The promoters of the company are completing arrangements for its construction.

Markham, Ont.—A new milling company is being formed here with a capitalization of $75,000. It is proposed to erect a mill of the latest type, valued at $60,000, a short distance from Markham station. A. Ward Milne, of this town is interested in the company.

Winnipeg, Man.—The Stovel Co. will replace the building recently destroyed by fire with premises estimated to cost $250,000. The building will be located on the site on Bannatyne avenue, which is partly occupied by the plant established there some time ago. John Woodman, of Winnipeg, is the architect.

Personal

Charles L. Marble has been appointed manager of the Wayne Oil Tank & Pump Co., of Woodstock, Ont.

W. S. Robertson, general manager of the Electric Power Co., has sent in his resignation to take effect at the end of the present month.

R. J. Gordon, D.L.S., is returning to Lethbridge, Alta., as resident engineer for the provincial government. He formerly held that position here.

LOGGING MACHINERY FOR BURMAH

In a communication to the Departmest of Trade and Commerce, H. R. MacMillan, Special Trade Commissioner, states that an opening exists in Burmah for Canadian machinery used in logging operations. Authority has just been granted by the Government for the purchase of one logging engine, to haul logs up to a maximum of 3 tons weight, a distance of 3,000 feet over smooth ground, and although previous machines have been of American construction, a Canadian machine would now be preferred. If this order were satisfactorily executed, it is stated that further business could undoubtedly be secured as forest development is only in its initial stages in Burmah. Canadian manufacturers should communicate immediately with the Conservator of Forests (whose name and address will be supplied on application to the Department. Refer File No. A-2017) and forward catalogues, price lists, and complete description of types of engines.

Wilford Philips, manager of the Winnipeg Electric company, has returned to Winnipeg after a sojourn of five months in California, for the benefit of his health.

J. E. Hargan, superintendent of the John Morrow Screw & Nut Co. plant, Ingersoll, Ont., was recently presented with a writing desk, chair and club bag by the employees.

Augustin Frigon, C.E., has resigned from the firm of Surveyer & Frigon, consulting engineers, Montreal, to become engineering manager of the Canadian Siegwart Beam Co.

William Angus for many years manager of the Royal Pulp & Paper Co., died at Montreal on May 12 aged 81. The deceased was born in Glasgow, Scotland and came to Canada 63 years ago.

Frederick Wells Avery, of Ottawa, millionaire lumberman, died on May 11 at the General Hospital, Montreal, following an operation. He was born in New York in 1852, and came to Canada in 1878.

F. Chandler, who has been the superintendent of the shell department in the Frost & Wood Co.'s works, Smith's Falls, Ont., for some time past, has resigned to accept a similar position in Toronto.

Roy Campbell, of Montreal, secretary of the Canadian Manufacturers' Association, has been chosen as secretary of the Trade Commission recently appointed by Sir George Foster to go to Europe and investigate possible trade openings among the allies.

R. B. Watson, general manager of La Rose Consolidated Mines for a number of years past, has resigned, and **G. C. Bateman,** who has been identified with the Canadian Mining & Exploration Co. will take his place. Mr. Watson will devote his attention to his private mining interests.

L. G. Ireland, who for the past three years has been general manager of the Brantford Hydro-Electric Commission and Municipal Railway Commission, has resigned. He has been appointed chief engineer of new hydro development in Eastern Ontario. He was for five years connected with construction work here.

Lieut.-Col. B. J. McCormick has completed arrangements for raising his new command, the 213th Battalion. Col. McCormick recently returned from Flanders. While there he was attached to headquarters, 4th Brigade, under Brig.-Gen. Rennie. He is a native of Port Huron, Mich., but held the position of Industrial Commissioner in Welland, Ont., for eight years prior to the war.

Trade Gossip

St. Boniface, Man.—The Rice Malting Co. of Canada will rebuild their plant, recently destroyed by fire. Manager, P. H. Rice.

The Canadian Locomotive Co., of Kingston, Ont., has received a contract for thirty locomotives from the Canadian Government.

Montreal, Que.—It is reported here that A. B. Mackay, of Hamilton, has acquired a controlling interest in the Montreal Transportation Co.

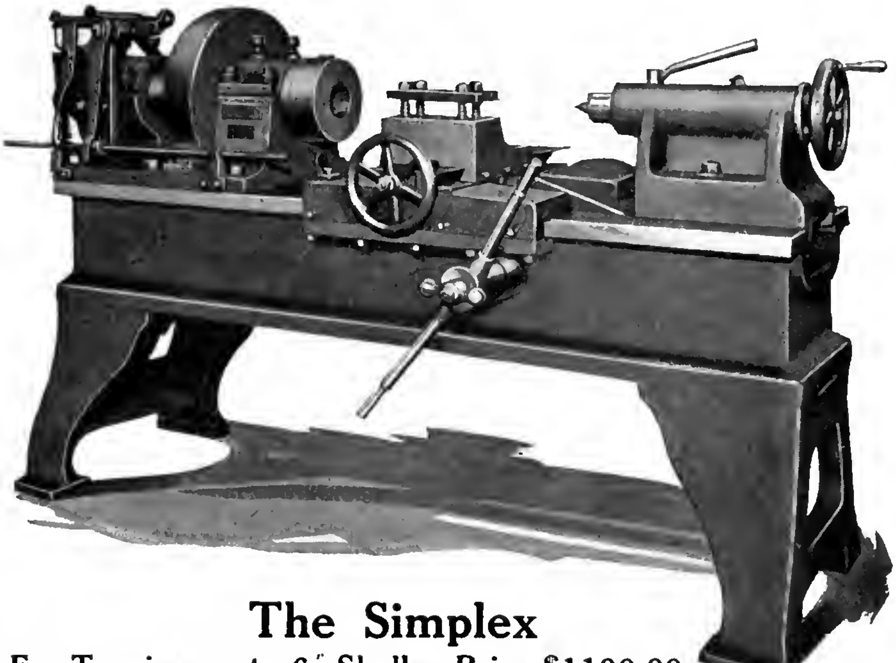
Williams Heavy Duty Projectile Turning Lathe

Shell Perfection! You are certain of that if you have the right machine, but how you dread an inspection if you are equipped with inferior machines. Illustrated here we show one of the most perfect machines for doing rough work, it does it well, it does it perfectly, which is just the machine you want. ACCURACY and SIMPLICITY are the qualities which have featured this machine.

SPECIFICATIONS

Length of Bed ....8′ 6″
Width of Bed ....19½″
Depth of Bed ....13″
Front Bearing of Spindle (4.5″ Shells) 6½″ dia. x 7½″......Bored 4 19-32″ dia.
Front Bearing of Spindle (6″ Shells) 8 13-16″ dia. x 7½″......Bored 6⅛″ dia.
Rear Bearing of Spindle..............5¾″ x 7½″
Flange on Front of Spindle..............12″ dia.
Size of Driving Pulley ....Dia. 13″ x 8″ face
Swings over Bed ....19″
Takes between Centres ....4′ 2″
Dia. of Turret (6 holes for bars 3″ to 2¾″ dia.) ....20″
Length of Saddle ....34½″
Feeds ....1-16″, ⅛″, 3-16″
Pilot Wheels geared 4 to 1. Ball thrusts throughout.
Shipping Dimensions (Boxed) 10′ 0″ x 4′ 0″ x 5′ 3″
Net Weight ....4,800 lbs.
Shipping Weight (For Export).........5,000 lbs.

Oil Pan is always supplied



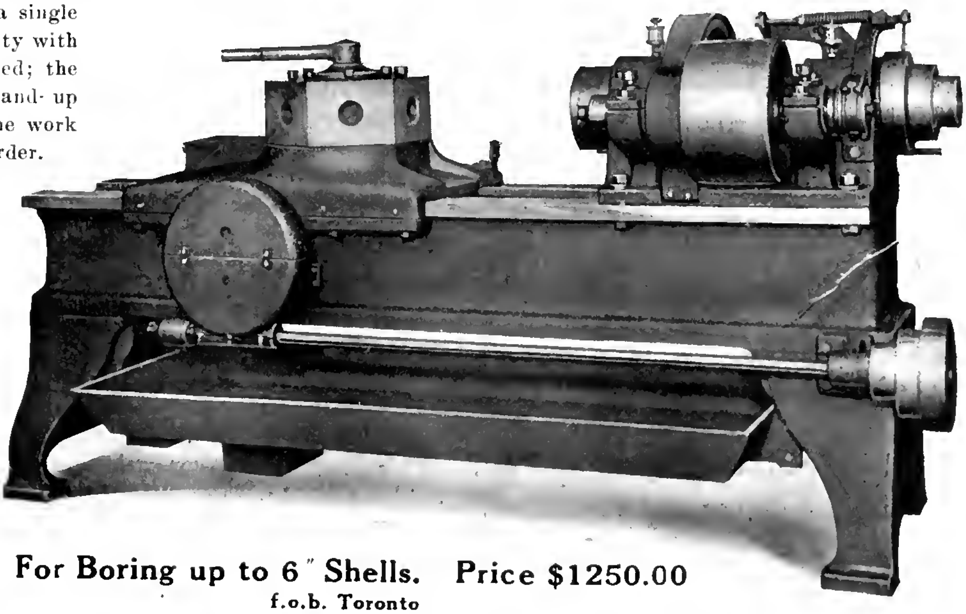
The Simplex
For Turning up to 6″ Shells. Price $1100.00
f.o.b. Toronto

Williams Shell Boring Lathe—Simplex Type

A tower of strength—this is proved by a single glance at the illustration. Note the solidity with which the head stock is bolted to the bed; the hexagon turret is built especially to stand up perfectly under the heaviest cuts, and the work it produces—it is of the most finished order.

All machines we exhibit have been subjected to a most severe test, just to see if they are as good as we think they are; the fact that we are advertising them is conclusive proof that they have stood the test. The large diameter spindle, fitted into bronze bushings, is provided with large collar on front end instead of threaded nose and chucks. The carriage and feed are of good length and securely gibbed to the bed. The feed is transmitted by belt from spindle to worm.

Profiling taper and other attachments can be supplied at extra cost, but must be ordered with the machine.



For Boring up to 6″ Shells. Price $1250.00
f.o.b. Toronto

THE A. R. WILLIAMS MACHINERY CO., LTD.
ST. JOHN, N.B. TORONTO WINNIPEG VANCOUVER
Canada's Leading Machinery House

Tungsten Ore in U.S.—The production of tungsten ores in the United States during 1915 broke all records. It was equivalent to about 2,165 short tons of concentrates, carrying 60 per cent. of tungsten trioxide, and was valued at more than $2,000,000.

The Paper Industry.—The growth of the export paper industry is one of the most striking factors in the recent industrial history of Canada. The great bulk of this trade is with the United States, which took about 14 million dollars out of about 16 million of exported news print paper in the 11 months of the fiscal year to February 28. Most of the small remainder goes to British Dominions.

The "Vancouver Island Marine," has been incorporated with a capital of $250,000, and head offices at Victoria, B. C. The company propose to engage in shipbuilding operations and to proceed with the construction of one or more vessels at the port of Victoria for the off-shore lumber trade. Charles J. V. Spratt, manager of the Victoria Machinery Depot, is the promoter of the Vancouver Island Marine.

Montreal, Que.—It is officially announced that the Cunard Co. have taken over the steamers owned and controlled by the C. N. R. The steamers in question are those which, before the war, were running to Avonmouth and Rotterdam, and the services will be maintained between Canada and ports in the United Kingdom and on the continent. Steamship services on the Pacific Ocean are also in contemplation.

Quebec, Que.—The St. Maurice Mines Co., with a capital of $400,000, has been incorporated to prospect and exploit mines in the counties of Montcalm, Pontiac and in the Temiscamingue, and also in the Abitibi region. The promoters of the company are Messrs Albert Edward Turner of London, England; W. E. Simpson, of Grantown-on-Spey, Scotland, engineer; Daniel E. Moran, of New York City, engineer; A. Doucet, C.E., and George Belleau, bank inspector of Quebec. The head offices of the company will be in Quebec City.

Machinery for Russian Government.—C. F. Just, the Canadian Trade Commissioner in Petrograd, cables that a large number of road rollers and other machinery will be wanted by the Russian Government in connection with the Empire roads construction programme. A number of 12-ton steam road rollers are required at once. The cable says the Russian Government also wants tenders on five locomotive cranes; working parts for ten ladder dredges, comprising buckets, chains, drums, steam engines, capacity 150 to 250 cubic metres per hour, total working depth five metres commencing frim water level. Firms tendering, to supply working drawings for remaining necessary plant, including pontoon constructed in Russia; early delivery essential; quotations f.o.b. New York.

Large Order For Locomotives.—It is announced that the New South Wales Railway Commissioners have let a contract for the supply of locomotives approximating in value to $5,000,000. The contract is for 300 engines, to be supplied by the Clyde Engineering Co. of Sydney, during a period of five years. This is understood to be the largest order for locomotives that has been given in the Commonwealth, and it represents the policy of the Government of making the State self-contained industrially. This order may be of interest to Canadian manufacturers of locomotive supplies, as a considerable proportion of the materials and fittings used in the construction of the engines will, as heretofore, likely be imported from oversea.

Newcastle, N.S.W., Steel Works.—Since the industry was started, over $7,500,000 has been expended on the Newcastle Steel Works, and additional plant is being installed to cope with the active Australian demand for iron and steel products. Arrangements have been made for the erection of four more open-hearth furnaces (making seven in all) and the first of these is nearly completed. The demand for pig iron has been much larger than anticipated, while the demand for steel products is considerably in excess of the present productive capacity of the works. The production of steel at a time when freights are abnormally high and imported steel scarce is invaluable to manufacturers in Australia.

Tenders

Charlottetown, P.E.I.—Tenders will be received by the engineers, R. S. & W. S. Lea, Montreal, until May 20, for the erection of a pumping station and installation of a one-million-gallon pump at Charlottetown.

Toronto, Ont.—Tenders will be received addressed to the chairman, Board of Control, City Hall, up to May 23, 1916, for the complete construction of a steel frame, brick-faced tile addition, including heating plant, to the St. Clair avenue car barn, Christie street. Specifications and forms of tenders may be obtained upon application at Room No. 311, Department of Works, City Hall.

Toronto, Ont.—Tenders addressed to the secretary-treasurer of the Board of Education will be received until May 23, 1916, for science apparatus, chemicals, etc., for Collegiate Institutes and High Schools. Specifications may be seen and all information obtained at the office of the clerk of supplies, Room 308, City Hall.

Toronto, Ont.—Tenders will be received by the chairman Board of Control, City Hall, up to May 23, 1916, for the supply and delivery of: One single truck, double end, street car, completely equipped; one car body, double end, single truck; equipment for one single truck car, electrical equipment; equipment for one single truck car. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Contracts Awarded

Winnipeg, Man. — The Dominion Bridge Co., has been awarded the contract for a bridge between Winnipeg and St. Boniface to cost $360,000.

Fredericton, N.B. — The Provincial Government has awarded a contract for the construction of the Aroostook River Mouth Bridge to Engineers & Contractors, the price being $20,000.

Rosetown, Sask.—The contract for the construction of the Rosetown Northern Telephone Co. system has been awarded to the Northwestern Construction Co., of Saskatoon. The contract calls for the construction of forty-eight miles of telephone line.

Hamilton, Ont.—The Board of Control's recommendation that the Gutta Percha & Rubber Co., be awarded the contract for 1,000 feet of 2½-inch hose was amended to read 500 feet. The Goodyear Rubber Co. was awarded the contract for the other 500 feet.

New Incorporations

Harry Tolton, has been incorporated to manufacture machinery at Berlin, Ont., with a capital stock of $150,000. The provisional directors are Edwin P. Clement, E. W. Clement, Wm. Clement, of Berlin.

The St. Charles Chemical Co., has been incorporated at Ottawa with a capital of $100,000 to manufacture all kinds of chemicals at St. Charles Barromee, Que. Incorporators, J. A. Guibault and H. Trudeau of Joliette, Que.

The Parker Shoe Co.has been incorporated at Ottawa with a capital of $49,000 to manufacture boots and shoes, leather goods, etc., at Preston, Ont. The incorporators are: S. H. Parker, G. Fink, and W. S. Hadson, all of Preston, Ont.

Winning the Buyer's Favor

The best possible buyer is not made an actual buyer at a single step.

It is one thing to win the buyer's favor for an article and another to make adjustments incident to closing the sale. Winning the buyer's favor is the work of trade paper advertising.

Under ordinary conditions it should not be expected to do more.

Catalogues

The York Mfg. Co., York, Pa., have issued a bulletin dealing with the "York" enclosed refrigerating machine which is well adapted for markets, dairies, ice cream factories, etc. The bulletin is illustrated and the important features of the machine are briefly described.

The Bayer Steam Soot Blower for Torizontal Fire-Tube Boilers, is the title of a new 16-page bulletin just published by the Bayer Steam Soot Blower Co., St. Louis. The bulletin shows details of construction and operation and contains the experience of users and manufacturers. A free copy will be sent to engineers on request.

Fittings.—The Detroit Valve & Fittings Co., Detroit, Mich., have issued catalogue No. 3 to the trade. The piece list on straight size fittings has been revised and a piece list added on all reducing sizes. These lists are based on the estimated average weights of the fittings and so figured that piece fittings take a uniform discount. This list includes malleable iron fittings for steam, gas and water, drainage fittings and specialties also malleable and grey iron castings. The price lists are very complete and the catalogues fully illustrated.

The Prevention of Scale Formation is the title of a bulletin issued by the Buckeye Skimmer Co., Toledo, Ohio. The basis of the bulletin is a short talk on scale, and its removal from steam boilers by using the "Buckeye" boiler skimmer. The formation of scale in boilers and its removal is dealt with in a general way followed by a description of the "Buckeye" skimmer and its method of operation. The claims made for this apparatus are dealt with at length accompanied by illustrations showing it installed in various types of boilers.

Electric Pyrometers.—Catalogue No. 1,400 deals with an interesting range of electric pyrometers made by the Wm. H. Bristol Co., Waterbury, Conn. The development of the "Bristol" pyrometer and general advantages of the thermo-electric systems are dealt with followed by a partial list of important applications. The various types of pyrometers, indicating switchboards, and scales are illustrated and described accompanied by price lists of all sizes and types. Particulars are given of therm-o couples with illustrations showing the method of application. The catalogue concludes with a partial list of users and illustrations showing a great variety of temperature measuring instruments manufactured by the company.

Book Review

The Motor Car, by Duncan McMillan. 157 pages, 7¼ in. x 4¾ in., 136 illustrations. Published by Longmans, Green & Co., London, Eng. Price 90 cents net. This book is the latest addition to the Longmans' Technical Handicraft Series of publications. It is written in a clear and comprehensive manner and deals with the construction and operation of the modern motor car in such a way as to be readily understood by those who do not necessarily possess an extensive knowledge of mechanics. The author's idea has been to take a straight course through the typical modern motor car, beginning at the engine and finishing at the road wheels. The principles underlying the various parts of the car are explained and illustrated by means of simplified diagrams, these being followed by illustrations from drawings and photographs of the actual parts. All variations from the main types have been excluded and no special attempt has been made to deal with the details of the latest designs. The book contains fifteen chapters devoted to the following subjects. Horse power and rating, general arrangement of a car, the engine, carburetors, ignitions of various types, clutches, the gear box, the differential bearings and brakes, steerings and controls, care of the car and tires, the two-stroke engine, and sleeve and rotary valve engines. The book is printed in bold type and the drawings, etc., from which the illustrations have been taken have been carefully prepared. It contains a lot of valuable information for both the car owner and mechanic set forth in a clear and concise manner.

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Five cents each insertion when box number is required. Each figure counts as one word. Display rates on application.

FOR SALE

SIX-FOOT METAL PLANER FOR SALE—practically new. Apply A. Graham Boyd, 100 Front St. E., Toronto. (14)

TWO FOX TURRET LATHES FOR SALE—splendid condition. Ideal Foundry, 960 Gerrard St. East, Toronto. Phone Gerrard 1055. (15)

FOR SALE — ONE NEW FORD SMITH Grinder for Shrapnel. A short time ago we purchased five, find four will take care of our work. The National Manufacturing Co., Brockville, Ont.

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

FOR SALE — ONE (1) PLAIN LANDIS Grinder, 10" x 30"; In good working condition. Price reasonable. Apply Canada Forge Co., Welland, Ont. (20)

FOR SALE—2—16 x 2 POWER FEED TURrets; 1—16 x 1½ Turret with threading attachments; 1—16 x 2 Turret; 1—16 x 8 Engine Lathe; 1—12 x 8 Tool Lathe; 1 Speed Drill. Apply J. A. Harvey, 16 Pearl St. (21)

FOR SALE—GARAGE IN GOOD WHEAT district. Snap for a good, practical man. About forty cars in vicinity. Will sell cheap if taken at once. Address Box 74, Hanley, Sask. (13)

FOR SALE—ELECTRIC GENERATOR TO run 80 lamps, 110 volts, 300 r.p.m., including switchboard and indicator; in good condition. Richards-Wilcox Canadian Company, London, Ont.

AUTOMATIC SCREW MACHINES

Three (3) Gridley, single spindle, 2⅛" cap., motor drive, including motors, each $1500

Five (5) No. 2 Brown & Sharpe, each $500

Hartford, 2¼" cap. $850

Hartford, 1½" cap. $750

THE CO-OPERATIVE USED MACHINERY COMPANY

50 Church Street - - New York

Suite 482 Telephone Cortlandt 665

FOR SALE

FOUNDRY AND MACHINE SHOP WITH stove patterns and stock. Splendid opening. Apply Mrs. Thomas Johnston, Kemptville, Ont. (23)

1—C.G.E. TYPE 10—20 H.P. INDUCTION Motor—60 cycles, 220 volts, 45 amps.—1200 R.P.M., complete with Auto Starter. Pulley on Motor 12" Diam. x 10" Face. Cummer-Dowswell, Ltd., Hamilton, Ont.

FOR SALE—ONE NEVER-USED WESTINGhouse Motor, Type CCL, 5 H.P., 200 Volts, 16 Amperes, 3 Phase, 3000 Alts., 700 R.P.M., full load, equipped with starting compensator and frame and 6" pulley with 5" face. Canadian Machinery, Box 189. (16)

FOR SALE — TWO GOLDIE-McCULLOCH Wheelock Engines—cylinders 16" diameter, 38" stroke; both engines now running, but will be replaced with Hydro-Electric. Engines guaranteed to be in perfect condition, and will be sold complete with belt wheels, one 14' x 35" face and one 12' diameter with 24" face, also belting if required. Canadian Consolidated Felt Co., Berlin, Canada. (19)

FOR SALE OR RENT—MACHINE SHOP AND foundry, with garage. Good machinery, good locality. Lots of cars and boats. Power and rent very cheap. Box 334, Carleton Place, Ont. (21)

FOR SALE — COMPLETE LUMBER AND lath mill machinery, daily capacity seventy-five thousand feet, consisting of gang, single and double bandsaws, engine, boilers, etc. Fully equipped blacksmith and machine shops. Silsby fire engine, 2 streams of 2½ inch; good order. Log loader, capacity fifty thousand feet, ten hours; almost new. Exceptional manufacturing site bargains. Address The Rathbun Company, Deseronto, Ont. (18)

ELECTRODES — THE PROPRIETORS OF letters patent No. 127080, relating to "Process of manufacturing iron for use in alkaline accumulators," and No. 127081, relating to "Active masses for positive electrodes of electric elements, etc.," desire to dispose of the patents or to grant licenses to interested parties at reasonable terms, with a view to the adequate working of the patents in Canada. Inquiries to be addressed to the actual proprietors, Svenska Ackumulator Aktiebolaget Jungner, Stockholm, Sweden. (13)

SITUATIONS WANTED

CHIEF ENGINEER — 26 YEARS' EXPERIence. Factory and Central Station, Alternating and Direct Current, Gas or Steam Engines, efficiency guaranteed, own instruments, best of references. Box 181, Canadian Machinery. (12)

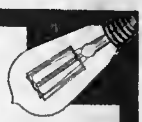
AS MAINTENANCE ENGINEER OF FACTory, power or lighting plant, where economy is a factor, wide experience, best of references. Box 180, Canadian Machinery. (12)

FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY
970 Queen St. West, Toronto (15)

WANTED



Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN LAMP FACTORY
ST. CATHARINES, ONTARIO

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

SITUATIONS VACANT

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month. Box 184, Canadian Machinery.

WANTED—FIRST-CLASS BOILER MAN TO take charge of battery of water tube boilers, 1200 H.P., which will be increased. Should be familiar with steam engine and air compressor. Reply, giving particulars of experience and salary expected. Box 191, Canadian Machinery. (19)

MECHANICAL SUPERINTENDENT WANTed—for plant of the Starr Manufacturing Co., Limited, Dartmouth, Nova Scotia (near Halifax), operating one 10-inch and one 18-inch train of rolls, producing merchant bar iron. Manufacturers of ice skates and bolts and nuts. Address the company direct, stating age, experience, salary required, giving references, also when services will be available. The Starr Manufacturing Co., Limited, Dartmouth, N.S. (22)

WANTED

WANTED BERTRAM WAVING ATTACHment for 4.5 Shells, with or without Lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson Limited. (R.T.F.)

WANTED—HYDRAULIC PUMP, GOOD FOR 2,000 lbs. pressure capacity for 16" diameter cylinder press; belt-driven preferred. Canadian Consolidated Felt Co., Ltd., Berlin, Canada. (18)

ENGINEER WANTS AGENCIES FOR MONTreal and district. Side line or specialties, on commission basis. X.Y.Z., Canadian Machinery, Montreal. (19)

WANTED — BERTRAM WAVING ATTACHment for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

BOILERS WANTED—TWO SECOND-HAND, about 150 H.P.; at least 80 pounds working pressure under Ontario Government Boiler Regulations. Give full particulars, Box 198, Canadian Machinery. (19)

AND MANUFACTURING NEWS

A weekly newspaper devoted to the machinery and manufacturing interests.

Vol. XV. TORONTO, MAY 25, 1916 No. 21

EDITORIAL CONTENTS

THE MACLEAN PUBLISHING COMPANY, LIMITED

JOHN BAYNE MACLEAN, President. H. T. HUNTER, Vice-president.

H. V. TYRRELL, General Manager

Publishers of Hardware and Metal, The Financial Post, MacLean's Magazine, Farmer's Magazine, Canadian Grocer, Dry Goods Review, Men's Wear Review, Printer and Publisher, Bookseller and Stationer, Canadian Machinery and Manufacturing News, The Power House, The Sanitary Engineer, Canadian Foundryman, Marine Engineering of Canada.

Cable Address: Macpubco, Toronto; Atabek, London, Eng.

ESTABLISHED 1887.

CANADIAN MACHINERY AND MANUFACTURING NEWS

PETER BAIN, M.E., Editor. B. G. NEWTON, Manager.

Associate Editors,

A. G. WEBSTER, J. M. WILSON, J. H. RODGERS.

CHIEF OFFICES:

CANADA—Montreal, 701-702 Eastern Townships Building; Toronto, 143-153 University Ave., Telephone Main 7324; Winnipeg, 22 Royal Bank Building, Telephone Garry 2313.
GREAT BRITAIN—LONDON, The MacLean Company of Great Britain, Limited, 88 Fleet Street, E.C., E. J. Dodd, Director. Telephone Central 12960. Cable Address: Atabek, London, England.
UNITED STATES—New York, R. B. Huestis, 115 Broadway, N.Y., Telephone Rector 8971; Boston, C. L. Morton, Room 733, Old South Building, Telephone Main 1024. A. H. Byrne, 1101-5-6-7 Fort Dearborn Bldg., 105 W. Monroe St., Chicago, Telephone Randolph 3234.
SUBSCRIPTION PRICE—Canada, Great Britain, South Africa and the West Indies, $2 a year; United States, $2.50 a year; other countries, $3 a year; Single Copies, 10 cents. Invariably in advance.

Export and Trade Expansion Number

May 25th 1916

SECTION OF THE HARBOR OF MONTREAL, QUE., LOOKING SEAWARD.

Data Relative to Foreign Trade, Commerce and Transport

Compiled and Selected

When we consider the number and variety of metal-working plants that have either sprung into existence or have been materially extended as a result of war orders more or less varied and large, and when thought is given to the certain eventuality that this business will one day sooner or later cease, nothing is more natural than that the minds of those responsible for the maintenance and development of our commercial and manufacturing activities, should be exercised in the endeavor to seek new opportunities while simultaneously cultivating more intensely the old. It may be said that the latter is quite normal with respect to the former.

A PERUSAL of these editorial pages will convince the most skeptical that the foundations of a great industrial future for Canada have been well and truly laid. As in the past, and more than likely for all time to come, our agricultural achievement will, however, figure largely in our rate of progress towards a foremost place among the commercial nations of the world. The reclamation of our mineral wealth and the judicious conservation of our forest resources will each contribute their no insignificant quota in the direction indicated.

Canadian manufacturers have, so to speak, found their feet, as a result of war-made opportunities right to their hand, by which we mean that they have become alive to their capacity for doing things, and, in consequence, have developed an expertness that was aforetime believed non-existent, and still much less appreciated as being simply latent. Their business sense has been quickened and their outlook broadened, being just comprehensive enough now to manufacture competitive lines of commodities here in Canada to meet the requirement of any or every corner of the globe; distance being no drawback.

Such an attitude is "catching," but meantime intensely so, hence we find live municipalities within our borders awake to the new opportunities for plant establishment and location which manufacturing production to export or foreign order will create. It is a sign, further, that our citizens individually and as a whole are equally enthusiastic in the matter of our commercial and industrial development as are our manufacturers.

The Russian Feature

No attempt has been made in these pages to give undue prominence, much less to glorify the prospects of export business between Canada and any particular country, unless exception be made as to Russia, yet, in her case, the data given will be found to embody little more than a statement of conditions existent, which have been verified over and over again from the most trustworthy sources. Russia of all countries of the world has, of her own initiative, and seconded by the efforts of people well informed as to her requirements, made her trade opportunities more widely known to her nation friends than has any other Allied or neutral country in which German commercial influence predominated, and through which German manufactured products found a ready market. As a result, agency and enterprise have undoubtedly been directed more towards her than to others.

Not only, then, have we an organization whose activities are concerned wholly with war-created export demands from all quarters, and who are represented in Russia by one of her native-born sons who has been resident in Canada for a number of years and who has travelled abroad extensively, but we have had in addition the benefit of the activities of the staff of our Department of Trade and Commerce at Ottawa. Our business men have further been privileged to hear Russia's commercial possibilities discussed in a straightforward and comprehensive way by exporting and shipping representatives who in the past have been and are now in the closest possible touch with the Russian commercial situation. In a word, the needs of Russia are perhaps best known, and, therefore, the opportunities for Canadian manufacturers are perhaps the best available just at the particular moment.

From an industrial standpoint the descriptive articles in this issue covering our mineral and lumber resources, our

steel production, and our manufactures of steel and wood commodities therefrom; our harbor, port and navigation facilities and aids, indicate clearly that we possess natural material and locational advantages. The enterprises featured are, however, but representative of many others of a like kind and of an even more varied nature. In the realm of steel-making, mention may be made of the Steel Company of Canada, with its plants at Hamilton, Fort William, Belleville, Brantford, Gananoque and London, Ont., and at Montreal and Lachine, Que.; also of the Dominion Steel Corporation, Sydney, N.S., with which is incorporated the Dominion Coal Co., etc.; and of the Algoma Steel Co., at Sault Ste. Marie, Ont.

Shipbuilding

In the sphere of shipbuilding and marine engineering, in addition to Canadian Vickers plant on the St. Lawrence, we have the Davie Drydock and Shipbuilding Co. at Levis, Que., while on Lake Ontario we have the Kingston Drydock and Shipbuilding Co., the Polson Iron Works, Toronto, the shipyards and drydocks of Muir & Sons, and M. Beatty & Sons at Port Dalhousie and Welland, Ont., respectively. On our Upper Lakes—Superior and Georgian Bay, the shipbuilding plants of the Western Drydock & Shipbuilding Co., and of the Collingwood Shipbuilding Co., have the distinction of being capable of building the largest lake vessels afloat. On our Pacific Coast, shipbuilding and ship repair plants of varied capacity are to be found, while, as a result of the new conditions arising out of the war and the projected service to be afforded by the Panama Canal, steps are being taken to secure a further increase in establishment, as well as a Federal Government subsidy for the substantial support of the whole.

General Engineering

Other directions in which Canadian industrial and manufacturing enterprise has made special headway are those of freight car and locomotive building, heavy marine and other purpose steel casting and forging production, heavy and powerful hydro-electric and its kindred mechanical equipment, electrical instrument and specialty work, machine tool and accessory apparatus, also steam power plant main and auxiliary engines, boilers and contributory mechanisms, agricultural machinery of wide and varied application, etc. In view of the foregoing it will be noted that Canada is particularly well equipped to develop now an export trade on a competitive basis with all or any of the older manufacturing countries who in times past have catered to the requirements of those less favored in the matter of industrial resources and facilities.

A considerable export business has already been established between Canada and different countries abroad through the activities and enterprise of individual firms and corporations, and through the medium of the Export Association of Canada. This has consisted of locomotives, freight cars, raw, semi-finished and finished materials of construction and general engineering, embracing wire nails, belting, twist drills, wire rods, barbed wire, marine forgings, machine tools, steel billets, lumber, textile products and numerous miscellaneous products for general and domestic utility.

It has not been possible within the scope of the space available to us, to feature as comprehensively as we had desired, the various considerations to be accounted by our manufacturers in prosecuting an export campaign, or the variety procedure to be followed in the conduct of an export business. Sufficient has been said in these directions to serve as a guide, however, meantime. It cannot be too strongly emphasized that success in creating a market for our products, is wholly dependent on our attitude to the prospective consumer. The success of Germany in appropriating so much of the world's trade in the past was due to her all-consuming desire to give each national unit not only what it wanted at a price, but in the way it was wanted. By making this maxim or series of maxims the basis of their operations, there is little fear of failure in such efforts as our manufacturers may put forth to mix freely in a world-wide commerce. A knowledge of the language of the particular country to which export effort is directed, is also a very essential feature, which leads us to suggest that wherever possible the export manufacturer should have at least one member of his staff a more or less expert linguist.

We are indebted to the Montreal Harbor Commission for the cuts and data forming the article on Canada's Port Facilities, etc., and to the Exporters' Encyclopedia for the concise statements covering prevailing export and shipping customs and practices.

WEIGHTS AND MEASURES IN INTERNATIONAL TRADE

FUTURE developments in foreign trade will involve a wider use of the metric system of weights and measures, which is in almost universal use in all countries outside of the British and Russian Empires. The necessity of using systems other than avoirdupois, imparts more than a passing interest to data of this nature, especially at this time.

So far as all ordinary commercial purposes are concerned, the United States and British measures of length and weight, of the same denomination may be considered as equal, but the liquid and dry measures of similar denominations vary widely in the two countries.

Theoretically, the standard measure of length of both countries is the length of a pendulum vibrating at intervals of one second, at sea level in the latitude of London, suspended in a vacuum and at a temperature of 62 deg. Fahr. The length of such a pendulum is supposed to be divided in 39.1393 equal parts, called inches, 36 of these inches forming the standard yard of both countries. However, when the Parliamentary standard was destroyed by fire in 1834, attempts to restore it by measuring a pendulum proved futile.

Yard and Meter

The present British Imperial yard, as determined at a temperature of 62 deg. Fahr. by the standard preserved in the Houses of Parliament, is recognized as standard throughout the country and in the government departments of the United States, although not so declared by Act of Congress.

The meter, which is the unit of length of the metric system was intended to be one ten-millionth part of the earth's quadrant or the distance from either pole to the equator. This length was measured, and a set of standards prepared which rest in the archives at Paris. Although errors in the original calculations for determining the length have been discovered, the standards remain as originally prepared.

BRITISH AND METRIC EQUIVALENTS

Measures of Length

1 metre=39.37 in. or 3.28083 ft.
.3048 metre=1 ft.
1 centimetre=.3937 in.
2.54 centimetres=1 in.
1 millimetre=.03937 in. or 1-25 in. nearly.
25.4 millimetres=1 inch.
1 kilometre=1093.61 yds. or .62137 mile.

Measures of Weight

1 gram=15.432.
.0648 gram=1 grain.
28.35 gram=1 ounce avoirdupois.
1 kilogram=2.2046 pounds.
.4536 kilogram=1 pound.
1 tonne or metric ton=
.9842 ton of 2240 pounds
1000 kilograms
2204.6 pounds
1.016 metric tons=
1016 kilograms=
1 ton of 2240 pounds.

RUSSIAN WEIGHTS AND MEASURES AND THEIR ENGLISH EQUIVALENTS

Weights

1 dolya=0.6856 grain.
1 zolotnik (96 dolyas)=0.15 oz.
1 lot (3 zolotniks)=0.45 oz.
1 funt (96 zolotniks)=0.9 pound.
1 pood (40 funts)=36 pounds.
1 berkovetz (10 poods)=360 pounds.
1 oz.=6.65 zolotniks.
1 pound=1.108 funt.
1 ton=62.02 poods.

Measures of Length

1 vershok=1.75 in.
1 arshine (16 vershoks)=2 ft. 4 in.
1 sazhen (3 arshine)=7 ft.
1 verst (500 sazhens)=3,500 ft.
1 English yard=
0.4286 sazhen
1.286 arshines
1 English mile=
1.509 versts.
754.29 sazhens.

MARINE INSURANCE

THE shipper can arrange to have his insurance to attach from the time his goods are receipted for by the vessel — either sail or steam — or her agents, and to continue the risk after discharge at port of destination until delivered to the consignee; but this arrangement must be specially made, because the ordinary policy of insurance covers the risk only when the goods are actually laden, and terminates with discharge of the goods at port of destination. Should the vessel on which the goods are shipped be diverted from her voyage to an extent that the voyage is considerably extended (as, for instance, through the closing of the Panama or Suez Canals), shippers should make certain that their shipments are covered by their marine insurance policies for the extended voyage. Exceptional risks which are not incorporated in the policy may be provided for; this also must be a matter of special agreement when making the insurance.

It is assumed that, unless specified to the contrary, all goods are shipped "under" deck; therefore, when goods are shipped "on" deck, it must be so stated in the application for insurance. Goods laden on deck are insured free of claim for damage arising from exposure to the elements.

The ordinary policy of insurance excludes claims for damages or what is termed "particular average" on certain classes of goods, such as grain, etc. When it is desired to insure such goods subject to "particular average" it must be specially provided for in the application for insurance.

Free of "particular average" under 5 per cent. means that no claim for partial loss or damage will be allowed by the insurance company unless the actual loss or damage amounts to 5 per cent. or more of the amount for which the shipment has been insured, as set forth in the policy.

In marine insurance, the amounts recoverable as a total loss if not declared, i.e., under an open policy, are: For "merchandise," the prime cost, including the expense of shipment and the premium and charges of insurance; for the ship, its value at the outset of the voyage, including the outfit, stores, and provisions for the crew, their advance wages, and the premium and charges of insurance; for freight, the gross amount of freight expected, together with the premium and charges for insurance. As a claim for total loss cannot extend beyond the full amount insured in the policy, the documents required to substantiate such a claim must be supplied to the underwriters free of charge. These documents are:—(a)—protest; (b)—set of bills of lading (endorsed, if necessary, so as to be available to the underwriters); (c)—policy or certificate of insurance (endorsed, if necessary); (d)—assignment of interest to the underwriters. This last document is of considerable value in the event of salvage refunds in the case of salved goods, as any claim for salvage expenses will be sent direct to the underwriters.

DISTANCES IN NAUTICAL MILES

THE distances given in nautical miles indicate the shortest practicable routes when steaming from New York (the Battery), and are those furnished by the Hydrographic Office, Washington, D.C.

SIGNIFICANT!

RICHARD MARTENS, vice-president and managing director of the shipping and engineering firm of R. Martens & Co., Inc., sailed from New York, May 15, on the Anchor Liner California for Petrograd. During his six months' stay in the United States he has completed the organization of his American Company, has studied the manufacturing situation and has addressed gatherings of prominent merchants and manufacturers in important trade centres. A number of American engineers will join Mr. Martens in Petrograd in June for a conference, after which they will tour Russia and ascertain in what form consumers will be able to use American products. These engineers, in the past six months have visited important plants and have prepared reports indicating what American manufacturers are now ready to sell to Russian buyers.

RE-OPENING OF THE PANAMA CANAL

WHILE the re-opening of the Panama Canal to vessels drawing up to 30 feet of water has just been announced, there is every indication, says the New York "Journal of Commerce," owing to the difficulties experienced by shipping when the waterway was closed to traffic last fall, that the use of the canal will not be resumed on a normal basis for some months to come.

The confidence which was once felt in the canal was destroyed by that experience, and with the services of vessels at their present high value, representatives of steamship companies say that they are naturally hesitant to place themselves in a position where a repetition of the delays with attendant money losses, even if traffic were only temporarily suspended, would be possible. The consequence is that those companies which depended for the maintenance of their service on the Panama Canal will not resume immediately, but will wait until the canal has been tested.

Lines which will send their ships through the canal at once are those maintaining services where the use of the canal means merely a shortening of the voyage. In this class are companies operating vessels from Atlantic ports of the United States to the west coast of South America. The temporary suspension of traffic would work great hardship on these lines, because of the delay in taking the longer course and the necessity to provision ships differently unless the canal is used, but the saving in expense is such as to warrant running the risk.

SUPPLY OF CREOSOTE

THE supply of creosote, because of its use in preserving railroad ties, telegraph poles, and other timber employed on railways is a matter of considerable moment. It will, therefore, be of interest to know that, according to statistics published by the Bureau of Foreign and Domestic Commerce, the amount of creosote imported into the United States fell from 48,839,020 gallons in 1914 to 34,432,028 gallons in 1915, a decrease of 34 per cent. Owing to the average value per gallon having increased from 6.2 cents to 7.8 cents, the imports only decreased 11 per cent. in value. In 1914 33,873,173 gallons came from the United Kingdom, 9,861,996 from Germany, 3,868,786 from Belgium, 777,662 from the Netherlands 3,000 from Sweden, and 454,430 from Canada. In 1915 only four countries were concerned in the supply —the United Kingdom with 31,695,587 gallons, Germany 5,527 gallons, Canada 2,680,809 and Japan 50,105.

ITALY AND THE METRIC SYSTEM

AT a meeting of the London, England, Chamber of Commerce recently, Baron Qaaranta Bernardo di San Severino, a well-known commercial man from Italy, discussed some phases of the commercial relations between the United Kingdom and Italy. Without hesitation he criticized quite frankly the antiquated methods of British commerce, which unfortunately had driven the Italians against their will, to take advantage of the modern and enterprising system of German commercial penetration in Italy.

Lord Southwark, who presided, said that trade after the war with Italy would be of the greatest importance to both countries. When this terrible war was over it was their wish that the United Kingdom and Italy should remain life-long commercial friends. Since the war had commenced the London Chamber of Commerce had done much to bring buyers and sellers together in the two countries. In past years a great deal of Italian trade had slipped past England, and that was really due to the fact that they had no good trading banks. He believed, however, that a new arrangement between Lloyds' Bank and the London County and Westminster Bank was going to meet the difficulty in that respect.

Frank Criticism

The Baron said that he thought English goods were even too much sought after these days in Italy. There was a positive craze for everything English; and yet English goods were steadily disappearing from the Italian market, and German and Austrian goods had inundated the whole country. One of the first reasons for that was the low price of German goods. Another difficulty was the way in which England continued to employ its antiquated system of weights and measures, while Germany used the metric system. British firms also made the mistake of using the English language in their communications.

Another trouble, said the Baron, is that English exporting firms obstinately insist upon selling in Italy not what the Italians want, whether what they ask for be pretty or ugly, in good taste or in bad taste, but "what the English consider the Italians ought to want." The Germans, on the other hand, having made a long and profound study of our habits and customs, and of our needs, which are constantly increasing in proportion with the increasing prosperity of our country, not only provide us with what we want, but keep in constant touch with even our most eccentric caprices, which they are ready to satisfy no matter what strange forms those caprices may take.

The English, on the contrary, who have never troubled themselves to study our markets, have never been able to free themselves from their traditional conservatism, which is so injurious to their commerce. They insist upon imposing their own will and tastes on the purchaser, invariably forgetting that it is, after all, the buyer and not the seller who is the sole arbitrer of the situation, and they rigidly oppose, therefore, any suggestion of modification, however slight, in the articles of which they presumably wish to dispose. Italy is now set upon putting an end to the inoculation of Pan-Germanism; and a decree has been issued only a month ago in Italy with the object of putting an end to all German commerce in Italy. The moment has arrived when a great impetus ought to be given to British exports to Italy.

H. L. Symonds, who proposed a vote of thanks to the Baron, said that all British commercial men felt how absurd it was to retain the old system of weights and measures for modern business. At the same time, British business had not proved so bad in the past. In fact it had financed the whole war.

A. Barton Kent, in seconding, thought that Germany got her hold on Italy by penetrating the country with the German banking system, which showed more sympathy and support for traders than the British system. He referred to the scheme of a channel tunnel, of which he had always been a strong advocate; a scheme which would greatly help British and Italian trade, and which would, he thought, have been of immense use to us if it had been completed before the war.

E. R. Bartley Denniss, M.P., Liverpool, said that in Great Britain, where a population of forty-six millions had to be kept alive, foreign trade was of the first importance. The coming conference at Paris would discuss the best way of keeping that foreign trade going, but he did not believe the delegates had yet formulated any plan, or that the cabinet knew what its representatives were going for. It was their duty to urge upon the Government some common policy for after the war trade between the Allied Powers, and they ought to act on that at once. After the war they ought to be in a position to finance Italy as Germany had done, and take the place which Germany had occupied. Such a plan would be very much to the advantage and profit of British traders.

MACHINERY MARKET IN ARGENTINA

THE Bureau of Foreign and Domestic Commerce, Washington, D.C., have published the report prepared by Special Agent J. A. Massel relating to the markets for machinery and machine tools in Argentina. Mr. Massel discusses the predominant position secured in the past by certain of European nations, especially Germany, and sets forth the causes that gave rise to that condition. He points out specially the methods that have been effectual in this field, and, with those as a basis, he formulates what he regards as a practical and desirable plan for increasing American trade. The monograph contains many descriptions of machines and tools actually in use in the countries mentioned.

BUSINESS WITH HONG KONG.

THE following statement is from the London and China Telegraph:—Hong Kong is affected by the order prohibiting Manchester and other places from continuing to supply goods to German firms in China. These goods, remarks the Colonial Gazette, are sold with a German trade mark or "chop," and the natives have got used to them. The position is that the articles have to a very large extent been made in Great Britain, but have been handled by German firms—an arrangement which has been to the benefit of both parties. Unless the British firms can now step in and establish direct connections, the Germans will no doubt obtain some goods from neutral sources and continue to mark them with their brands, but it will not be easy to do so, and very high prices will have to be paid. The breaking up of the old combination will create a new situation, and it is to be hoped that British merchants in Hongkong will use it energetically in their own interests and those of British trade.

LIABILITY OF STEAMSHIP COMPANIES

THE liabilities of a steamship company are defined by special Act in force, as a rule, in most commercial and industrial countries. In general, this Act declares, among other things, that "if the owner of any vessel transporting merchandise or property to or from any port in the country to which the Act applies, shall

exercise due diligence to make his vessel in all respects seaworthy and properly manned, equipped and supplied, neither the vessel, her owner or owners, agent or charterers, shall become or be held responsible for damage or loss resulting from faults or errors in navigation or in the management of said vessel; nor shall the vessel, her owner or owners, charterers, agent or master be held liable for losses arising from damages of the sea or other navigable waters, acts of God or public enemies, or the inherent defect, quality of vice of the thing carried, or from insufficiency of package, or seizure under legal process, or for loss resulting from any act or omission of the shipper, or owner of the goods, his agent or representative, or from saving, or attempting to save, life or property at sea, or from any deviation in rendering such service."

The statute applies to coastwise shipping as well as to shipping between domestic and foreign ports. The carrier is still liable for damage arising from negligence in loading, stowage or the proper delivery of the cargo. As to other matters, it is bound simply to supply a seaworthy boat and officers and crew chosen with reasonable care. For negligence of officers and crew in navigating the vessel the owners are not liable.

TRADE INQUIRIES

THE following inquiries relating to Canadian trade have been received by the Department of Trade and Commerce, Ottawa. The names of the firms making these inquiries, with their addresses, can be obtained on application.

398—Iron and Steel Bars and Steel Plates.—A Glasgow firm desires quotations, c.i.f. Glasgow.

401—Mild Steel Billets and Blooms for Rerolling.—Quotations wanted, c.i.f. Glasgow, for shipment May and June.

402—Annealed Wire—A Glasgow firm are in the market to purchase annealed wire, baling and other qualities. Quotations c.i.f. Glasgow, for shipment May and June.

403—Bars, Plates, Sheets.—A firm in Glasgow wishes to receive quotations from Canadian exporters of iron and steel-finished materials, such as bars, plates and sheets, etc.

404—Bars, Sheets, Plates, etc.—A Glasgow firm asks to be put in touch with Canadian exporters of finished iron and steel in bars, sheets, plates, hoops, wire, etc.

405—Bolts, Nuts, Rivets, etc.—A Glasgow house desires to hear from Canadian manufacturers of iron and steel manufacturers, such as bolts, nuts, rivets, nails, etc., c.i.f. Glasgow.

407—Wire Nails.—A Glasgow house wishes to receive quotations from Canadian firms.

DELIVERY OF GOODS

ALL goods should be delivered to the steamer in the name or for account of the shipper who has contracted for the freight room, or in whose name the shipping permit has been arranged. The said permit should be presented either with the goods, or to the steamship company's clerk at the receiving pier before delivery is made. Goods that are to be shipped "in bond" should not be delivered until the steamer on which they are to be shipped is at her loading berth.

SHIPPING THROUGH FORWARDING AGENTS

DURING the war in Europe the services of the forwarding agent and freight broker are invaluable. Being right on the spot and in constant touch with the steamship companies, they are able to obtain for shippers the current freight rates (which are liable to sudden fluctuations); to arrange for freight room on outgoing steamers, prepare the bills of lading, consular invoices and other documents for a nominal charge, and attend to the details connected with transferring the shipments from railroad cars to alongside steamer or dock. The Exporters' Encyclopedia, published by the Exporters' Encyclopedia Co., Maritime Exchange Building, 78 Broad Street, New York, will enable the shipper to check the routing, consular charges and other expenses with which he is billed, thus insuring him against errors. The forwarder occupies a very responsible position toward the shipper, and great care should be used in the selection of responsible concerns.

Manufacturers who consign their goods to a forwarding agent or a steamship company for shipment must comply strictly with the regulations of the country for which the shipment is destined, as to marking, weighing, packing, etc., and should advise their agent as to the number and character of the packages forwarded, the marks and numbers (if any) on same; the weights, both gross and net (in pounds or kilos, as the regulations may state), the nature of the contents of every package and the value of the different kinds of goods; whether to consign "direct" or "to order"; whether to affect insurance (stating the amount); whether or not to prepay freight and change (if optional); also what disposition to make of the bills of lading and consular invoices (if any), when issued.

The shipper should always send to his forwarding agent the "original" railroad bill of lading, as otherwise the latter may not be able to identify the goods when notified of their arrival by the railroad company, thus incurring delay in shipment and, possibly, storage charges.

PRICES OF COKE, BAR IRON AND STEEL IN BRITAIN

THE British Ministry of Munitions has issued the accompanying list of maximum prices on coke, bar iron and steel to be adhered to by producers in Great Britain:

Coke.

	Per ton net f.o.t. Makers' Ovens £	s.	d.
Durham:			
Blast-furnace coke	1	8	0
Special blast-furnace coke, guaranteed under 0.008 of phosphorus	1	10	6
Foundry	1	10	6
South Yorkshire, West Yorkshire, North Staffordshire, North Derbyshire, South Wales	1	4	0
Blast-furnace coke	1	10	0

Maximum Prices of Steel.

	Per ton f.o.t. Makers' Works £	s.	d.
Angles, ordinary sizes	11	2	6
Joists	11	2	6
Ship-plates	11	10	0
Boiler-plates	12	10	0
Rails (railway)	10	17	6
Sheet and tin-plate bars	10	7	6
Billets, ordinary mild steel	10	7	6
Billets, special	11	0	0

All plus usual standard extras.

Dar Iron.

	Per ton net f.o.t. Makers' Works £	s.	d.
South Staffs:			
Standard quality, ordinary sizes and merchants lengths	13	15	0
Marked bars (less 2½%)	15	0	0
South Yorkshire:			
Standard quality, ordinary sizes and merchants lengths	13	15	0
North of England:			
Standard quality, ordinary sizes and merchants lengths	13	15	0
Lancashire:			
Standard quality, ordinary sizes and merchants lengths	13	15	0
Scotch Bar Iron:			
Standard quality, ordinary sizes and merchants lengths	13	15	0

All subject to the usual extras for special sizes and qualities.

These prices are not intended to apply to sections rolled by manufacturers who do not make their own steel or puddled bars, and have to purchase blooms, billets, or puddled bars from other sources.

High-Speed Tool Steel

The maximum prices for high-speed tool-steel have been fixed as follows:—Finished bars, 14 per cent, tungsten, 2s. 10d. per lb. basis; ditto, 18 per cent.

tungsten, 3s. 10d. per lb. basis; usual trade extras for special sizes, etc. These prices are net delivered buyers' works.

The fixed prices for scrap, which must be returned to steel-makers' works, are as follows:—Millings and turnings, 5d. per lb. net, delivered steel-makers' works: bar ends, 6d. per lb. net, delivered steel-makers' works.

It should be added that these maximum prices have been fixed until June 30, 1916, and thereafter until further notice, and further, that the makers may sell for delivery after June 30, 1916, on the understanding that the fixed maximum prices ruling on the first day of any month during the period of the contract will apply to all deliveries made during that month. Those maximum prices are based upon the abnormal costs and conditions now prevailing, and must not be assumed to be indicative of any difference in relative values which may have obtained in the several districts before the war, and may obtain again after the war. This intimation must not be taken to authorize any sale or purchase or other dealing prohibited under the Defence of the Realm Regulations.

EXPLANATION OF COMMERCIAL TERMS

C. F. OR C. A. F. (Cost and Freight), means that the seller furnishes the goods and pays the freight—no other expenses, to place of delivery as agreed, all risks while goods are in transit being for account of the buyer.

C. i. f. (Cost, Insurance and Freight), means that the seller furnishes the goods, pays the freight and insurance to point of delivery, all other risks while goods are in transit being for account of the buyer.

F. o. b. destination, means that the seller pays all costs and assumes all risks until the goods reach the place of delivery as agreed.

F.o.b. steamer, means that the seller is to deliver the goods aboard the steamer in proper shipping condition, all subsequent risks and expenses being for account of the buyer.

F. a. s. steamer, means that the seller is to deliver the goods alongside steamer on lighter, or on the receiving pier of the steamship company in proper shipping condition, all subsequent risks and expenses are for account of the buyer.

TARIFFS INSUFFICIENT TO MEET TRADE COMPETITION

PREFERENTIAL tariffs, technical education, recruiting methods and preparedness for industrial progress by Canada after the war were the chief topics discussed at the recent annual meeting in the Board of Trade building of the Toronto branch of the Canadian Manufacturers' Association. W. C. Coulter, the retiring Chairman, in his address declared the complete and final suppression of the German menace will be achieved only when it is placed beyond the power of Germany to recover the trade temporarily lost. The products of the Central powers should be subject to such surtax and other disabilities as would effectively restrict their competition with the markets of the Allies. He also alluded to the system of taking eligible men for the colors regardless of the part they play in the economic field, and maintained that a national register was the only proper method, no matter from what viewpoint regarded.

More Efficiency Needed

S. R. Parsons of the British Imperial Oil Co., also favored the Allied Nations working hand in hand in a commercial way, but stated that while they might talk about preferential tariffs, if they relied on tariffs only they would rely on a broken reed. These things were well and good, but he thought they should fit themselves to take their places in the world of industry by the efficiency of their methods. Technical training was important in this respect. As regards the demands of recruiting he said he did not think they would mind that so much if they felt the right kind of men were taken, but they did not want to see the experts taken and the loafers left about town. He believed there should be more businesslike methods in regard to recruiting.

J. P. Murray remarked that reference had been made to protection against German competition. He thought the incoming Executive might give their attention to what might be expected from the United States, who were right at Canada's door, and would leave no stone unturned to get all the trade they could.

Twenty-Two Firms Quit

The report of H. Macdonald, Acting Secretary, stated that twenty-two firms in the membership went out of business mainly owing to unusual trade conditions. The Toronto branch membership now stands at 713 firms and corporations, a reduction of twenty-four, which might be explained by a membership campaign having had to be temporarily postponed owing to other work demanding the attention of the executive staff. The expenditures from the general revenue of the Association for branch purposes during the year amounted to $1,658, a decrease of $120 over the corresponding period of last year. The classification of membership indicates a revenue receivable from the territory allotted to the branch of $13,760, being a decrease of $140 on the previous year.

SHIPPERS' DRAFTS—FINANCING OF EXPORTS

WHEN a shipper is to draw on consignee for value with documents, he should consign the goods on both the "bills of lading" and the consular invoices (when such are required), to "order" and having endorsed the full set of both documents, "in blank" they should be presented with his draft (arranged in duplicate) and certificate of insurance to the banker through whom collection is to be made. When the foreign buyer has no open credit, the shipper should fix prices in foreign currency. Drafts on Europe should be made out in the currency of the country on which drawn. The banker through whom a draft is to be collected should always be instructed under what conditions the documents are to be surrendered—that is, whether they are to be delivered upon "acceptance of draft" or only after "payment of draft." Unless instructed to the contrary, unpaid or unaccepted drafts will not be "protested."

Despite the lack of Canadian banks abroad it is not so difficult to arrange foreign credits as many manufacturers suppose. The agencies of foreign banks here are in a position to collect money against consignments in most countries of the world. The endorsement of the bank with which a Canadian manufacturer does business will enable the latter to obtain practically the same accommodation from these foreign bank agencies as is granted to the manufacturers in Europe.

Until Canadian banks are established abroad it will be necessary to transact the business through these foreign bank agencies, and it would be to the advantage of the Canadian manufacturer to become better acquainted with the facilities that now exist.

BILLS OF LADING

THESE should be arranged on the steamship company's blanks and the description of the goods should correspond exactly with the receipts issued by the company to the shipper. These receipts should be attached to the "bills of lading" when the latter are presented to the company for signature. The "bills of lading" should be made out in exact accordance with the requirements of the steamship company. Bills of lading will not be signed until the prescribed form of "Shippers Export Declaration" is in the hands of the steamship company. "War tax" stamps are not required on ocean bills of lading.

HEAVY PACKAGES

UNLESS otherwise stated it is understood that the freight rates quoted by steamship companies apply to packages not exceeding 2 tons weight. When packages exceed this weight provision must be made by the shipper either to put the pieces aboard the steamer through direct arrangement with a hoisting company or to arrange with the steamship company for freight rates to include the hoisting charges. Similar extra charges are liable to be made at the post of destination or at transshipping points, so that shippers should be careful to find out when shipping heavy pieces just what the freight rate covers.

PACKAGES MARKED "FRAGILE"

SHIPPERS should appreciate that it is quite useless to mark in English only, such expressions as "handle with care," "this side up," etc., on packages intended for foreign countries where English is not spoken or understood by those who will handle the freight. If any such instructions are necessary, they should be stated in the language of the country for which they are destined, as well as in English.

FREIGHT RATES

CONTINUAL fluctuations make it impossible to indicate any standard freight rates. Some shipping companies issue freight tariffs, showing rates for different classes of freight to their ports of call, but as these tariffs are always subject to change without any notification, it is advisable to apply directly to the companies or to responsible freight bookers for rates at time of shipment, always indicating the weights, cubic measurement, and character of the merchandise. During the war in Europe, freight rates are liable to violent fluctuations, owing to the scarcity of neutral tonnage, liability to seizure, etc.

While the freight rate on ordinary cargo is based on either weight or measurement, what is called "special cargo," such as revolvers, jewellry, boots and shoes, and goods of an unusual value according to bulk, have always to pay an 'Extra Rate', based on a small percentage of the value, in addition to the regular freight rate. This extra change is made because of the necessity of special storage for its protection. In some cases cargo of this character is delivered specially to the Captain personally, and is placed under the care of the purser or some other responsible officer of the ship. The extra rate may vary anywhere from one per cent. to three and one-half per cent. of the value of the shipment. Sometimes, the extra charge is made on the basis of so much extra per 40 cubic feet, and sometimes on the basis of so much ad valorem, whichever produces the most revenue for the steamship company.

INAUGURATION OF NEW ELEVATOR EXTENSION

IMMEDIATELY following the successful launch of the new ice-breaker "J. D. Hazen," from the shipyard of Canadian-Vickers at Longue Point, on the afternoon of May 15, and graced by the presence of the same distinguished party of invited guests, the $800,000 addition to Montreal Harbor Commissioners' Elevator No. 1, was formally opened. The ceremony took place on the mezzanine or sacking floor, Lady Borden giving the signal which set the machinery in motion and opened a bin valve, thereby permitting a continuous stream of wheat to fall on the moving conveyor belt underneath. In so doing she inaugurated the full activity of what is now the largest seaport elevator in the world, the new addition giving elevator No. 1 a total capacity of 4,000,000 bushels.

Starting-up Function

The machinery was started by means of two small flags, of which the staffs were covered with insulated copper. By crossing these and thus connecting the copper ends Lady Borden established a current which gave a signal down in the power room. The power room immediately answered by clanging a gong, and men stationed at the proper points through the building threw in the machinery clutches. Lady Borden then opened the bin valve and the elevator was in operation. Those present next walked over to the huge dray elevator near Shed 3, and were lifted to the second floor, where an enjoyable collation awaited them.

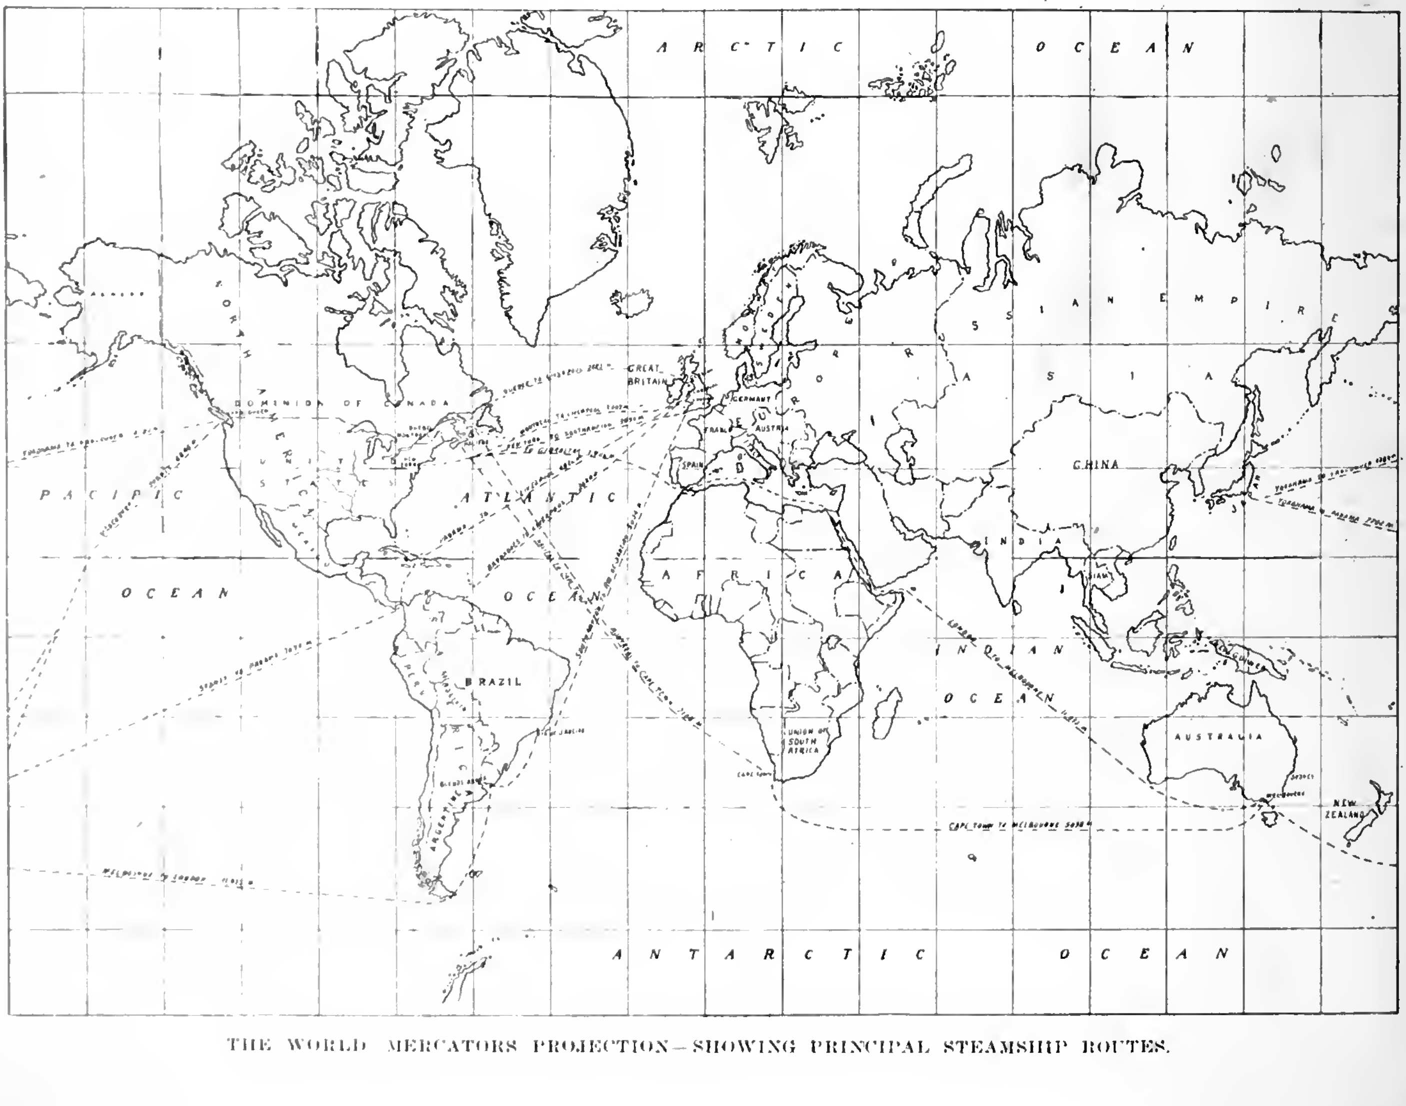
Presentation to Lady Borden

Here W. G. Ross, chairman of the Montreal Harbor Commission, addressed Sir Robert and Lady Borden, Lieutenant-Governor LeBlanc and Mrs. LeBlanc and the other guests. At the end of his address the occasion was signalized by the presentation to Lady Borden, by Mrs. W. G. Ross, of a magnificent silver tray with a striking representation of the new elevator engraved on it, together with the following statement:—"Presented to the Right Honorable Sir Robert Laird Borden, P.C., K.C.M.G., K.C., LL.D., Prime Minister of Canada, and Lady Borden, on the occasion of the opening of the extensions to Grain Elevator No. 1, Harbor of Montreal, Fifteenth May, 1916, by the Harbor Commissioners of Montreal, William G. Ross, President Farquhar Robertson, Brig.-General A. E. Labelle."

Mr. Ross stated in his address that the building would stand as one of the many monuments to business industry through the country. The contract for the extension, called for completion on July 15 next, but it had been completed two months ahead of time and at a cost about ten per cent. under the estimates. Grain from the elevator could be poured into the hold of any ship at its own berth in the greater portion of the harbor, and it could unload the largest lake steamer in 3½ hours after its arrival. It could fill the largest grain ocean-carrier in seven hours.

The harbor facilities had developed very quickly from the time 10 years ago when half a million bushels made almost the total amount of grain handled. In 1914 Montreal handled more grain than any other seaport of North America, and already this year before navigation opened 5,000,000 bushels were dealt with, most of it being bagged and shipped by cars to St. John and Halifax. During the winter 41,152 cars were handled on Harbor Commissioners' railway, twice the number of any previous winter.

After Mrs. Ross had presented Lady Borden with the silver tray for the Harbor Commissioners, His Honor the Lieutenant-Governor of Quebec, expressed his



THE WORLD MERCATORS PROJECTION—SHOWING PRINCIPAL STEAMSHIP ROUTES.

pride and pleasure at being present on the important and historic occasion.

Transportation Problems

Sir Robert Borden expressed his pleasure at seeing such development in the Port of Montreal as he had witnessed on his trip to the Canadian Vickers, to be present at the launching of the new ice-breaker. In connection with the launching he had been speaking of the industrial development of Canada, but the basic industry of Canada was agriculture, and the prosperity of Canada had to be built upon it. Her agricultural production could be immeasurably increased yet. Only one-tenth of the available fertile area of the West had been scratched, and the possibilities of expansion there confronted the Government with the pressing need of adequate transportation for the crops by water and by land, so that the grain would be taken in the most economical and efficient manner to the markets of the world.

Canals and railways were needed, and last, but not least, the development of the great national ports of Canada. He was pleased to be present at the opening of the greatest tidewater elevator in the world, and to see what he had seen. He prophesied a phenomenal development for the port in the next quarter century and he promised the cooperation of the Government of Canada for every reasonable purpose to secure the development needed. In Montreal what had been done was only the beginning of the great work intended in the future.

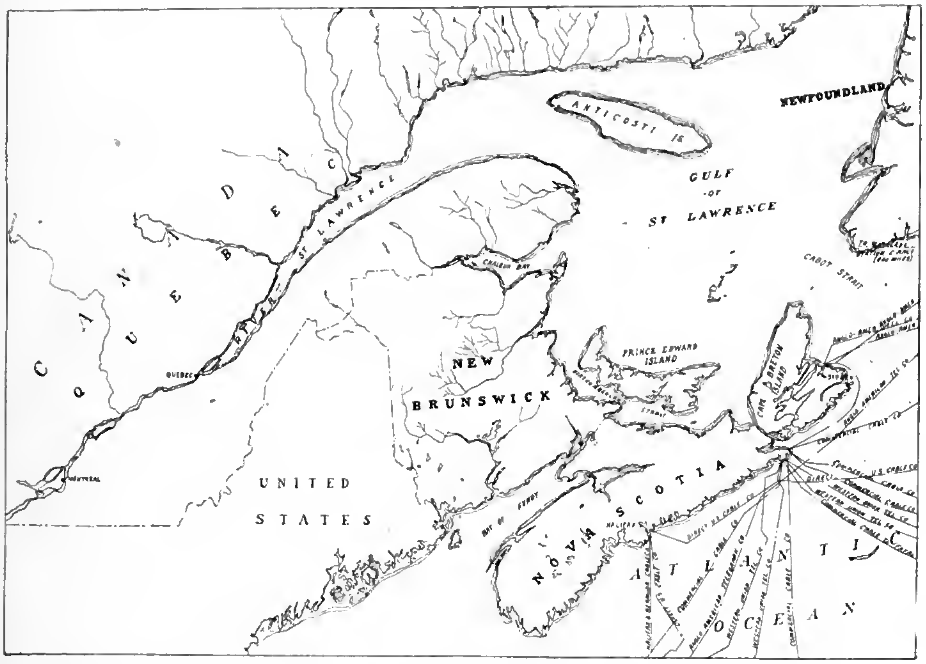


DIAGRAM SHOWING OCEAN CABLE STATIONS IN MARITIME PROVINCES.

OCEAN FREIGHT RATES

OCEAN rates are basel on prompt acceptance, usually by wire, and unless so answered are void as to contract, except by special agreement. As steamship agents always base their calculations on cubic contents, be careful in asking rates on bulky or measurement goods, like machinery of all kinds, to be explicit as to weights and measurements. Mark and number each package, and be sure the invoice tallies with the shipment. If you desire shipment insured, say so in your advice to the steamship company or forwarder, otherwise it is taken for granted that these details have been attended to by the shipper or his representative.

Send your advice to the steamship company or forwarder promptly, so they can have the necessary time between arrival of shipment at port of exportation and departure of steamship to complete details.

Ocean rates are quoted as a rule in sterling with primage to be added. The following table shows in what space the usual export commodities stow:—

Gross Ton	Stowage Cubic ft.
Apples	90
Bacon	65
Beef	50
Butter	70
Cotton, pressed	130
Cotton, unpressed	200
Cheese	70
Flour in sacks	55
Wheat in bulk	48
Peas	45
Corn in bulk	50
Hops	260
Lard	65
Leather	120
Oilcake	46
Oats	72
Oil	60
Ore	18
Pork	50
Resin	60
Syrup	44
Tallow	65
Machinery	65 to 250

SHIPPING RECEIPTS

WHEN steamship companies require any special form of receipt, blank forms should be obtained from them. If no special receipt is required, any ordinary form of receipt is sufficient. The marks and numbers (if numbered) on the packages should appear on the receipts, which should be arranged in duplicate, and the contents of the packages should be correctly described. The word "merchandise" should not be used. All receipts must be arranged in the name of, or be endorsed to, the party to whom the "bills of lading" are to be issued, and are returnable to the steamship company when "bills of lading" are issued.

DONALDSON LINE SS. "ATHENIA," TYPICAL OF CANADIAN OCEAN SERVICE.

Shipping Facilities at Canada's Principal Ocean Ports

Staff Article

Events of the past two years have amply demonstrated the ability of this country to contribute largely to the world's trade in manufactures as well as produce. Had the war not intervened, the marine activity of various ports would have materialized to a much greater extent than they have, but the present rate of development of industry and agriculture promise to tax even all projected developments to their full capacity in a few years.

DURING the season 1915 there arrived in the port of Montreal 815 sea-going vessels, with a tonnage of 2,261,374 tons. In view of the conditions prevailing in regard to maritime commerce such an amount of shipping must be considered very satisfactory, as, despite the requisition and retention by the British Admiralty of large portions of fleets regularly plying to this seaport, the tonnage mentioned is but 14 per cent. less than in 1914, which was 2,755,518, while a number of vessels dropped 101 from 916, or about 11 per cent.

This reduction in tonnage was doubly unfortunate for Montreal, as the phenomenal grain crop of that season, most of which would under normal conditions have passed through this port, was diverted to other channels. Such an occurrence is recognized as being due entirely to the existing state of hostilities in various parts of the world, and in due course the port of Montreal will again resume its consistent growth as the premier seaport of the Dominion of Canada.

VIEW OF HARBOR OF MONTREAL AS IT APPEARED IN THE YEAR 1830.

Early Development

From 1865, when the ship channel between Montreal and Quebec was deepered from 16½ ft. to 20 ft., until 1888, when a depth of 27½ ft. had been attained, the burden of the waterway had been carried by the Montreal Harbor Commission, who had paid the interest on the entire capital cost out of the harbor revenues. At this stage the policy was adopted of classing the ship channel with canals and other navigational works, resulting in the channel with all its dredging plant and staff being taken over by the Department of Public Works of the Dominion.

Since that time the energies of the Harbor Commission have been devoted to the perfecting of facilities in the way of plant, equipment, trackage, warehouse and dock accommodation, with results which have had no small influence on the development of Canadian overseas trade.

Grain Elevators

Chief amongst the many interesting features of the port is the elevator accommodation. Prior to 1910 the export grain handling equipment in Montreal harbor consisted of a 1,000,000-bushel elevator owned and operated by the Montreal Warehousing Company ;two obsolete wooden elevators owned by the Canadian Pacific Railway, since torn down; and a fleet of floating transfer elevators of miscellaneous construction and varying age and efficiency.

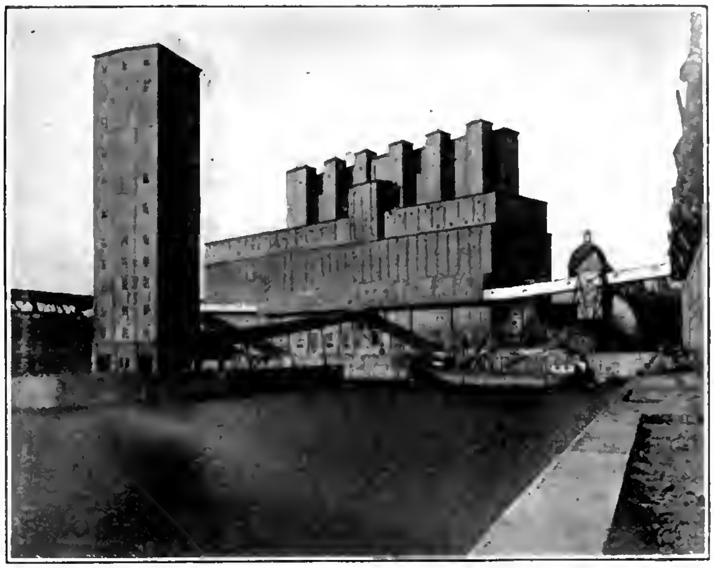
VIEW OF HARBOR OF MONTREAL IN 1872 SHOWING SAILING VESSELS.

Early in 1910 the Harbor Commissioners of Montreal determined to erect a new grain elevator of the highest class and most modern type, to have a capacity of 1,772,000 bushels, but in 1911 it was found that this extra storage room would be still insufficient to meet the needs of the port, and an extension was begun. The entire plant, known as Elevator No. 2, with a total capacity of 2,622,000 bushels, was put in operation in 1912.

The grain business increased so much as a result of the additional equipment that the construction of a 1,500,000-bushel addition to No. 1 Elevator was commenced in the spring of 1913, and was in operation at the beginning of 1915 season. Still another addition to No. 1 Elevator was required, and construction was started early last year on the completion of which the total capacity of the port will be:

No. 1 Elevator	4,000,000	bushels.
No. 2 Elevator	2,622,000	"
Grand Trunk Elevator	2,150,000	"

The full significance of such accommodation and the necessary equipment is realized from the following facts:



GRAIN ELEVATOR NO. 2 AND MARINE TOWER JETTY.

OCEAN GRAIN VESSELS LOADING AND WAITING FOR BERTHS. WINDMILL POINT.

Grain can be received from lake vessels and barges at the rate of 40,000 bushels per hour.

Grain can be received from cars at the rate of 36 cars per hour.

Grain can be delivered to ocean vessels at the rate of 75,000 bushels per hour.

Harbor Railway Terminals

The operation of the railway terminals has proved to be one of the most important and successful features of the development of the port of Montreal. These terminals extend from Victoria Bridge to Longue Pointe, a distance of seven miles, extending through the adjoining cities of Montreal and Maisonneuve, with a total track mileage of 44.9 miles. The matter of providing through railway connection from all parts of the harbor to all the trunk lines of the country began to receive attention in 1914, since when there has been remarkable development in the industrial business between manufacturing establishments on the water front, and the Canadian railways. As a result of the Commissioners' policy, coal, raw materials, supplies and manufactured goods are shunted into the industries, while manufactured goods and completed articles are shipped out to all points of the country on to the steamships in the harbor.

The rates charged for this service are so moderate, and the results so satisfactory, that an urgent demand has sprung up for immediate extension of the harbor terminals to new sites, and to the industrial wharves which are being specially constructed.

Shipbuilding and Repairing Facilities

Perhaps the most important factor in the development of the port, next to harbor accommodation, has been the provision of shipyard facilities for the prompt and efficient performance of repairs to either hull or engine. After a considerable amount of construction work, a site was prepared, which includes thirty acres of filled land for shipyard purposes with about six acres additional right-of-way for harbor tracks and roadway. The shipyard site is owned and operated by Canadian Vickers.

A prominent feature of the equipment is the "Duke of Connaught" floating

dry dock, which was built at the Barrow works of Vickers, and towed across the Atlantic in September, 1912. The maximum capacity of the dock, which is in three sections, is sufficient for docking ships up to 25,000 tons displacement, and up to 700 ft. in length. The value of such a unit as part of the port equipment is being increasingly recognized each year, a total of twenty-four vessels being docked and repaired during season 1915.

The shipbuilding berth is 500 ft. long, with a clear width of 116 ft. It is entirely enclosed so that work may be carried on continuously, despite the rigors of a Canadian winter. Engine and boiler shops, electrical construction department, with brass and iron foundries, enable repairs of any magnitude to be performed on vessels of all sizes and propelling machinery of any existing type, be it turbine, reciprocating, or internal combustion engines.

Safety and Insurance Aspects

Any reference to the port of Montreal would be incomplete did it not contain mention of the efforts made to insure the safety of navigation on the River St. Lawrence. While certain reductions have occurred since 1900, when the basis of rates at present in force was fixed, they still remain at a figure which is unduly high, having regard to the adequate dry dock accommodation in the river, the provision of which removed the last substantial argument against low insurance rates.

MONTREAL HARBOR, SHOWING SHEDS NO. 24 AND 25, ALSO RAILWAY TERMINALS JUST COMPLETED.

In November last an important conference was held between the Commissioners and representatives of British marine insurance companies, the discussion touching upon the great works of improvement accomplished by the Canadian Government through the Department of Marine and Fisheries, in deepening and widening the channel and establishing magnificent aids to navigation, and operating the signal service system, and all other means whereby the hazards of navigation in the St. Lawrence have been greatly lessened in the last few years. The degree to which such efforts have been carried will be understood from the fact that since 1900 Canada has spent $70,000,000 on the St. Lawrence route, the results showing up very clearly in the steady decrease in losses and accidents. The value of the St. Lawrence route to Canada's deep inland water connection with interior points was demonstrated during last season, when about 30,000 tons of nitrate of soda from Chile were transhipped at Montreal en route to the Western States, this being the only break in continuity over the entire distance of 10,500 miles. Among other features of note in the grain trade of Montreal during 1915 were the following: The shipment of 100,000 bushels of grain to New Zealand—the bagging of 2,800,540 bushels of grain at Elevator No. 2—the receipt of the first car of grain over the new Canadian Northern Transcontinental line, on Nov. 18, 1915—the receipt of the first car of grain over the Grand Trunk Pacific, the National Transcontinental Railway, and the Grand Trunk System on Nov. 25, 1915. These facts alone justify Montreal's claim to be considered the premier port of Canada.

DRY DOCK AND SHIP REPAIRING PLANT, CANADIAN VICKERS, LTD.

VANCOUVER, B.C.

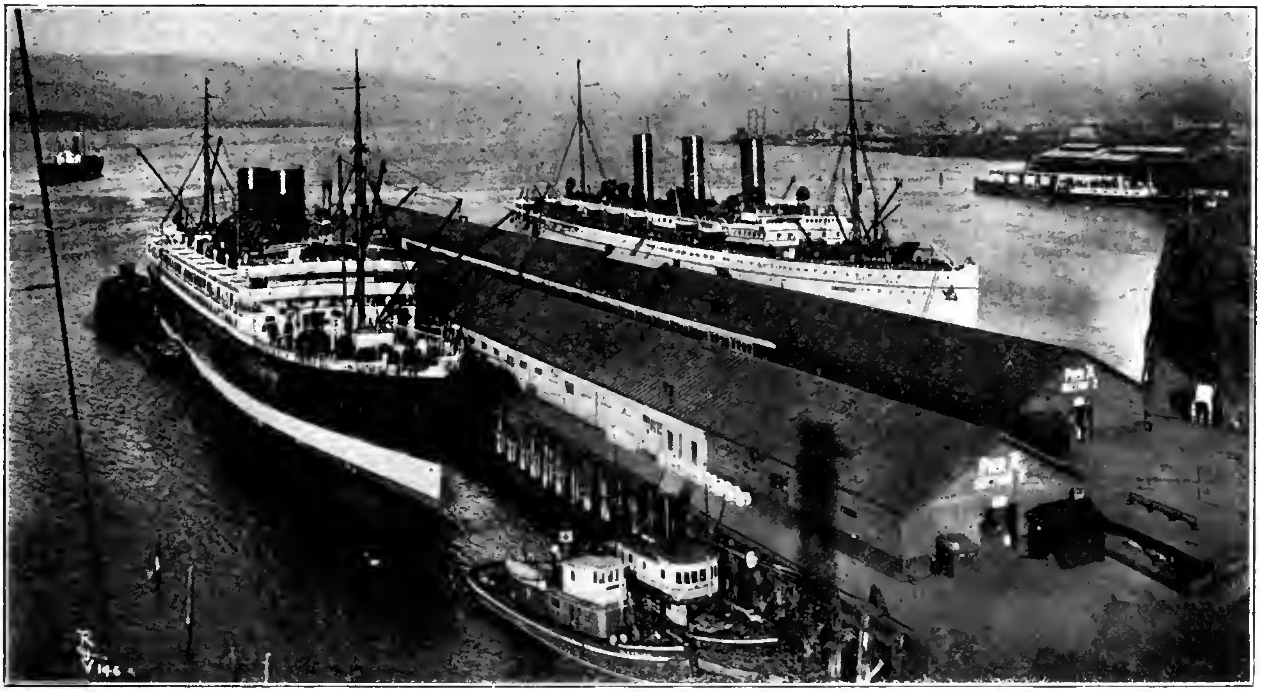
IN olden days, the harbor of Vancouver was described as the finest great harbor that indents the coast of British Columbia. Vancouver is the principal port of Canada on the Pacific coast and in addition to being the western terminus of the Canadian Pacific Railway is also served by the Great Northern line from Washington State, and the Canadian Northern Railway which recently completed its transcontinental line. Steamboat connection is provided by the Grand Trunk Pacific with Prince Rupert, the terminus of that railroad and the Pacific Great Eastern line of steamships also operates to the harbor.

The harbor is administered by a harbor commission with three members, empowered by an Act of Parliament, of May, 1913, and consists of an outer, central and industrial harbor. These are located a few miles northeast of the mouth of the Fraser River, the outer harbor stretching east and west a distance of six miles, by five miles wide, and connecting with the central harbor through the First Narrows which are from 35 to 72 feet deep at low water and about 500 feet wide. The central harbor is five miles long with a maximum width of two and a half miles, and is connected with the industrial harbor by the Second Narrows, 450 feet wide.

From the Second Narrows to Port Moody is a distance of about nine miles, the entire foreshore and navigable water forming part of the harbor of Vancouver. Already many industries are established on both shores, the location being conveniently situated with regard to shipping facilities, and adequate transportation facilities insure its future as Vancouver's manufacturing centre.

Some idea of Vancouver's potentiality as a port may be gathered from the fact that there are 98 miles of water front, nearly all of which is suitable for industrial and commercial purposes, with deep water and an almost entire absence of submerged rocks, shoals and other

VANCOUVER HARBOR, LOOKING UP, WITH C.P.R. NEW DEPOT IN FOREGROUND.



VANCOUVER HARBOR, SHOWING AUSTRALIAN AND ORIENTAL BOATS AT PIER "A."

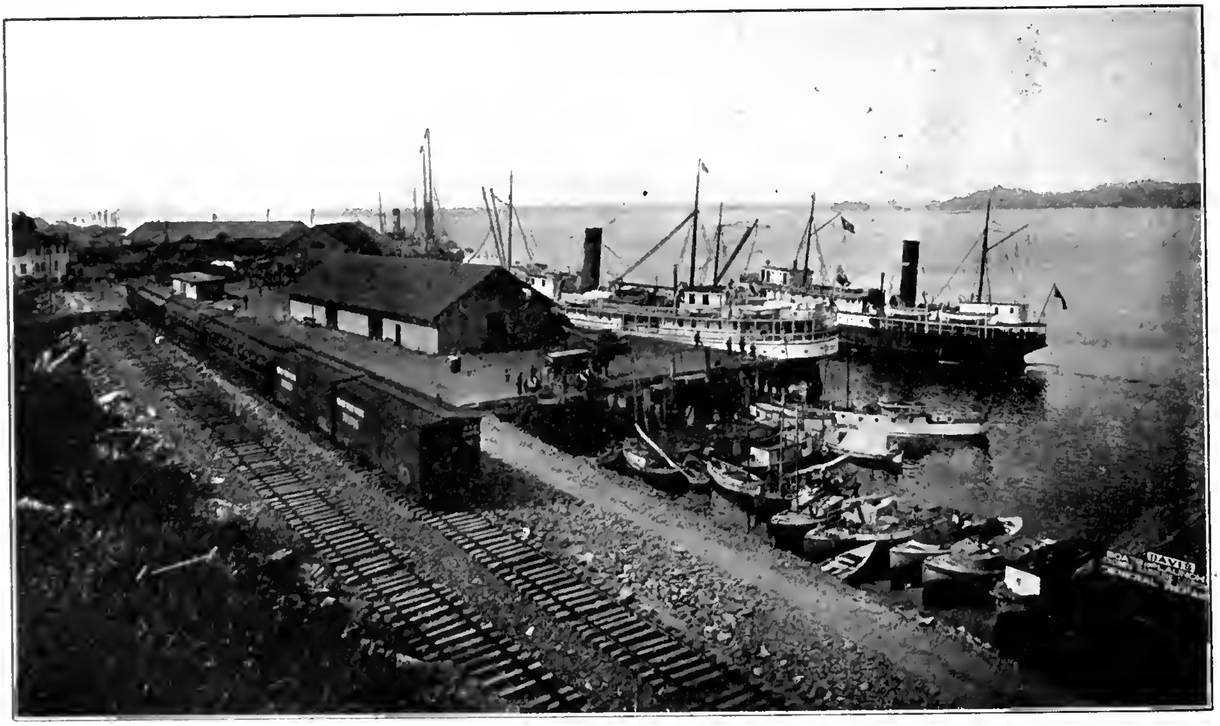
dangers to interfere with navigation.

Trade Capacity

Exports for the year ending March 31, 1915, amounted to 795,908 tons, consisting principally of lumber, fish and minerals. The shipping operations involved shipping arrivals totalling 7,668 coastwise vessels aggregating 3,305,458 tons and 1,463 foreign vessels aggregating 1,692,314 tons.

In normal times shipping facilities are of an ample nature; the Royal Mail steamers of the Canadian-Australian Line carry passengers and freight to and from the Antipodes on a 21-day schedule, the Blue Funnel boats, the largest freighters afloat, ply around the world, and a fleet of big vessels of the Andrew Weir Line, maintain a regular schedule between Vancouver and the Orient. Freight communication is provided between New York and Vancouver by a line of British vessels, and the Harrison Line, and a service to Antwerp places Vancouver in direct touch with the ports of Europe. The East Asiatic Co., the American Hawaiian Steamship Co., the Canadian-Mexican Pacific Steamship Co., the Pacific Coast Steamship Co., and many smaller shipping concerns are engaged in trans-pacific and coasting trade.

PRINCE RUPERT, SHOWING G.T.P. DRY DOCK AND SHIPBUILDING PLANT.



PRINCE RUPERT, SHOWING GENERAL VIEW OF HARBOR.

Future Developments

Provision for the future is under consideration, as is evidenced by the acquisition of an 80-acre site for a dry dock by a company subsidized by the Government. Among other improvements being carried out by the Govern-

ment is a reinforced concrete wharf, 800 ft. long with a frontage of 300 ft., and a depth of 35 ft. at low water. This wharf will be equipped with two sheds 800ft. long by 80 ft. wide, of the most modern type, and with up-to-date appliances for loading and discharging purposes, the operation of the plant being expected to devolve on the Harbor Commissioners.

A grain elevator recently completed has a total capacity of 1,250,000 bushels, receiving at 20,000 bushels per hour, and loading at 60,000 bushels per hour.

PRINCE RUPERT, B.C.

TEN years ago the site of Prince Rupert was little short of a wilderness of timber-covered land, the only means of ingress and egress being by boat. As the terminus of the Grand Trunk Pacific Railway it came into existence about eight years ago, and now has a population of 6,000 people.

A total wharf frontage of 1,685 feet has now been constructed and a floating dry dock with accessory plant enables general repair work to be undertaken on a large scale. When operated as a unit, the dry dock has a lifting capacity of 20,000 tons, which is the combined capacity of the two end units of 5,000 tons each and the centre unit of 10,000 tons. The accessory plant consists of foundry, boiler shop, machine shop, ship shed and carpenter's shop, with full equipment of cranes, power house, etc.

Prince Rupert occupies an excellent strategical position in regard to the Orient, being 500 miles nearer the East than any other terminus on the Pacific seaboard of the Dominion.

HALIFAX, N.S.

HALIFAX is situated on the Atlantic seaboard of the Province of Nova Scotia. It has a population of over 45,000 and possesses numerous industrial establishments in addition to being a Government naval station and the capital of the province. The favorable nature of the city's location in regard to supplies of raw material and distributing facilities in the shape of railway communication and shipping routes has been responsible for much of the manufacturing activity which prevails here.

Natural Advantages.

As an export point it enjoys considerable advantages in the matter of distance over other ports in the Maritime Provinces and in the United States. It is several days nearer Cape Town than New York is, and in normal times enjoys steamship communication with the leading seaports of Europe, South Africa, Australasia, West Indies, etc.

At the present moment construction is proceeding on new ocean terminals for the Canadian Government Railways. When completed there will be provided a passenger station building, abutting on a landing stage 2,000 feet long, the entire facilities of which will be devoted to the handling of passengers and their baggage, mail and express business, and ordinary cargo, the different classes of business being handled in rotation at specially equipped sections of the stage.

Future Developments.

The railway station accomodation is planned on a very complete scale with ample provision for handling large volumes of immigrant traffic. It is known as Halifax City Station and is designed to handle local passenger traffic in addition to steamship passengers.

Freight traffic is being taken care of by the erection of four new piers to replace smaller existing ones. The first of these was commenced in the fall of 1911, and was recently completed, having a length of 686 ft. and width 235 ft. The pier rests on 1,550 concrete piles, each 24 in. square, by 75 ft. long, this being the distance from rock bottom to track level at a height of 15 ft. 8 in. above extreme low water. The cost of the pier is approximately $690,000, while the building which is 677 ft. long by 198 ft. wide will cost about $333,000, not taking into account the cost of fitting temporary offices and rooms for use by officials, immigrants and regular traffic pending the completion of the railway station and passenger pier previously referred to.

VICTORIA, SHOWING GENERAL VIEW OF HARBOR.

VICTORIA, B.C.

THE capital of British Columbia is Victoria, situated at the southern end of Vancouver Island and having a population which advanced from 20,000 five years before to 65,000 in 1913. The principal industry is lumber, exports consisting chiefly of lumber, coal, whaling products, fish and fruits.

The entire dock development has been due to private enterprise, although a

Harbor Master, appointed by the Department of Marine and Fisheries is in charge of the movement of vessels in the port. Extensive developments are in progress at the present time including a 2,500 ft. breakwater and two large docks, the former sheltering a 90 acre area, while the latter will provide room for future traffic increase, having a berthing space of about 1,000 feet with a depth of 35 feet at low water.

Owing to the fact that most of the cargo is distributed throughout the island by coaster, the great bulk of the business is transferred direct from deep sea steamer to coaster, no railway connections are necessary at the wharves, local business being handled by motor transport from dock to destination.

Shipping Facilities.

Building and repair work is handled by at least five firms, one having a cradle 280 ft. long by 60 ft. beam which provides dry dockage for vessels up to 3,000 tons, and another having a cradle 150 ft. long by 35 ft. beam. Modern machine shops and foundries in various establishments enable marine repair work to be efficiently handled.

Esquimalt.

Four miles from Victoria is Esquimalt Harbor where the Government naval establishments are located. Here is located the yard of Yarrow, a branch of the well known British firm, in close proximity to which is the site of the new Government dry dock. This dock is to be proceeded with in the near future and will be 1,150 ft. in length, by 120 ft. in width, superseding the present graving dock of 480 ft. length which is not adequate for large boats berthing here for repairs.

ST. JOHN, N.B.

ST. JOHN, New Brunswick, is one of the busiest and most progressive of the Maritime cities of Canada. In furnishing troops, in manufacturing munitions, and in shipping grain and other supplies to Great Britain and the allies, St. John since the war began has done splendidly, eclipsing all previous records.

During the month of March, 1916, 109,225 tons of supplies were shipped through the Port of St. John to the United Kingdom and French ports. For the fiscal year ended March 31, 1915, the total value of exports through St. John amounted approximately to $45,000,000, as compared with $22,000,000 the previous year. For the fiscal year ended March 31, 1916, the total export values were $120,042,590, (an actual increase over the previous year of $76,169,658—a magnificent showing. The ocean tonnage through St. John in 1916 amounted to 179,361 tons, as compared with 82,143 tons in 1915.

The industrial plants of the city, including the lumber and pulp mills, cotton factories, sugar refinery, machine works, iron foundries, brush factories, nail plants, edge tool works, and leather factories, have been exceptionally busy. To some extent, these industries have been stimulated by war orders, but there are many in which the old lines are furnishing ample work. The manufacturing firm of T. McAvity & Sons have just broken ground for one of the largest iron and brass foundries in the lower provinces. The plant will be located in the eastern part of the city near the I. C. R. track. Under the agreement with the city the firm will have to spend at least $100,000 the first year. As the firm have contracts which must be filled by August, a very large portion of the works will have to be erected this year.

Harbor development work is proceeding at East St. John, and it is expected that the comprehensive scheme of development on the West Side, which was suspended soon after hostilities began, will be resumed this summer. There is a possibility of a revival of wooden shipbuilding as well.

St. John is looking for a big influx of immigrants after the war is over. The provincial government is preparing ready-made farms for these immigrants and for returned soldiers who may want to take up agricultural work. St. John was the first city in Maritime Canada to adopt the daylight saving plan, as it was the first to adopt the commission form of government and the town planning system. A plebiscite on the repeal of the commission form of government was recently taken, resulting in a larger vote in its favor than when it was first introduced.

When the Port of Halifax was opened, 1895-96, the total sailings for the season were less than one-half the sailings for the month just closed. Owing to the closing of the St. Lawrence River to navigation during the winter months considerable business accrues to both St. John and Halifax. The winter season extends from December 1 to April 30, and receipts for the season just closed amounted to $81,319.37, an increase of about 30 per cent. over 1914-15. During the same period sailings aggregated 206, an advance of 53 over last season.

CANADA'S TRADE

CANADA'S total trade for the month of April reached the remarkable total of $106,585,334, as compared with $65,221,031 for the corresponding period of the previous fiscal year. Being for the first month of the new fiscal years these figures seem to promise well for a record-breaking trade period. The increases are shown in both exports and imports. Merchandise entered for consumption amounted to $50,147,830, as compared with $28,391,640. These imports show a substantial increase in the free list as well as in dutiable goods, the free imports increasing from $11,776,319 to $21,218,746.

The grand total of imports, including coin bullion, amounted to $50,612,619, compared with $28,963,756.

Exports of foreign and domestic goods amounted to $55,372,720, as compared with $36,257,275 in the corresponding month of the last fiscal year. Exports of manufactured products increased from $13,221 658 to $21,573,078, and agricultural exports from $6,618.443 to $21,305,977. Mineral exports increased from $2,975,002 to $3,690,744, and forest exports from $1,929,440 to $2,287,939.

Another large increase is shown under animals and their produce, exports of which amounted in April, 1915, to $3,312,498, but which amounted in April of this year to $5,112,105.

DOMINION STEEL CORPORATION

THE president of the Dominion Steel Corporation, Mark Workman, accompanied by Wm. McMaster and W. G. Ross, has been at Sydney, N.S. looking over the steel and coal properties of the company. His visit was in connection with matters relating to the compilation of the yearly figures.

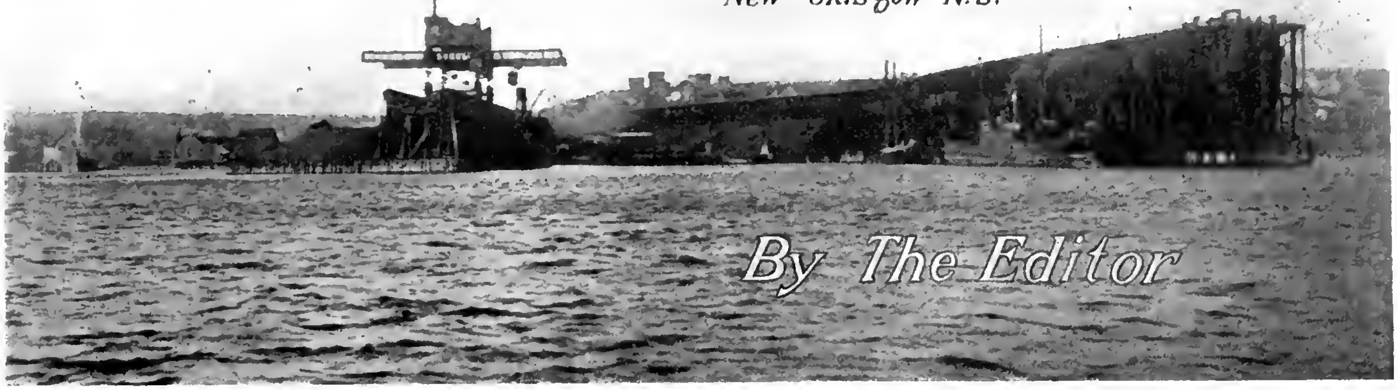
"I find there are a number of problems to be overcome," says Mr. Workman, when asked for a statement. "Our coal business is being handicapped by various difficulties, the chief of which is the fact that we have scarcely any steamer tonnage to transport the product of the mines. The Admiralty found it necessary to requisition the majority of our coal carriers for war purposes.

"Take Montreal, for instance; in normal times we would be shipping large quantities of coal up the St. Lawrence River at this season of the year, but under present conditions it is very difficult for us to fulfill our obligations with our customers in that district, among whom are many munition factories, which are now finding their output endangered from this cause.

"As regards the steel company," continued Mr. Workman, "we are hoping for a reasonable output of our products to offset as far as possible the increased cost of the necessary raw materials used in our various operations. Prices of supplies required for steel making purposes have advanced enormously since the outbreak of the war, and this in itself constitutes quite a difficult problem."

The Nova Scotia Steel & Coal Co.

Wabana Nfld., Sydney Mines and New Glasgow N.S.



The history of "Scotia" from its inception down to the present is a fascinating one, because full of life, energy and optimistic determination. In bringing Canada's coal, iron and steel industries to their present degree of successful achievement, the Nova Scotia Steel & Coal Co., it will be observed, has at no time been lacking in prominence of contributory effort.

AROUND the growth of the Nova Scotia Steel & Coal Co. and its parent organizations is woven in large measure the record of Canada's coal and iron industries' achievement.

The Coal Side

The history of the company down to the present—1916—dates back nearly three centuries to the time when Nicholas Denys, then Governor of Eastern Acadia, was granted certain concessions that included the whole of Cape Breton Island, one of the richest coal fields in the world. Although at that early day coal was known to exist at Sydney, this immense property was not systematically developed until the organization, in the early part of the nineteenth century, of the General Mining Association of London, England. The first shaft was sunk in 1830 and, from that time onward, coal mining in Cape Breton has been marked by a steady growth. In 1900, the holdings of the General Mining Association were taken over by the Nova Scotia Steel & Coal Co., in whose control the property still remains.

The Steel Side

Equally interesting as the coal feature is the story of the rapid growth of the iron and steel branches of this now great industry. Starting in 1872 with a capital of $4,000 and a working force of eight men, the little Hope Iron Works of New Glasgow quickly developed. Six years later, in 1878, a larger plant having become necessary, the whole undertaking was removed from the centre of the town of New Glasgow to a point two miles down the East River, then called Smelt Brook, but now known as Trenton or North New Glasgow. There was begun the manufacture of railway car axles. In 1882 it was decided to engage in the manufacture of steel, and the Nova Scotia Steel Co. was organized with a capital of $160,000, an increase in ten years to forty times the original capital. One year later a Siemens-Martin open-hearth steel plant was completed, and a 26-inch blooming mill installed—the first of its kind in Canada—together with a 22-inch plate mill. Two years later a bar mill was added. In 1889, the Nova Scotia Forge Co. and the Nova Scotia Steel Co. were amalgamated under the name of the Nova Scotia Steel & Forge Co.

COL. THOMAS CANTLEY, PRESIDENT AND GENERAL MANAGER.

The New Glasgow Iron, Coal & Railway Co. was organized in 1890 with a capital of $1,000,000. Extensive iron ore lands were purchased, including a valuable section on the East River, near Pictou, a line of railroad from Ferrona Junction to Sunny Brae was constructed and many other improvements made, the most important of which was the building of a large coal washing plant, coke ovens, and modern blast furnace at Ferrona.

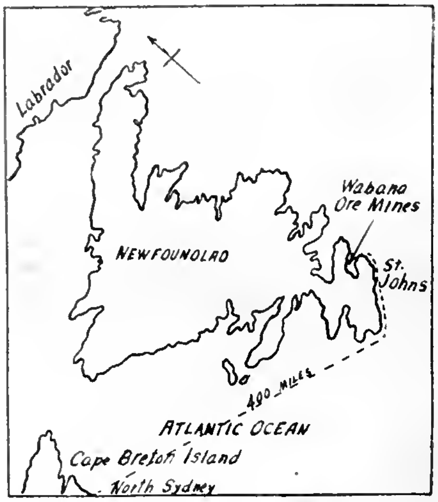
In 1894, the New Glasgow Iron, Coal & Railway Co. acquired the now famous iron ore deposits of Bell Island, Conception Bay, Newfoundland, and added a new name, Wabana, to the list of the world's shipping ports. The mines were opened up, machinery installed, and a double track ropeway, storage pockets and pier were constructed. The first shipment of ore was made on Christmas Day, 1895. Since then about 13,000,000 tons of ore have been shipped from Wabana.

Consolidation of Interests

The Nova Scotia Steel & Forge Co. and the New Glasgow Iron, Coal & Railway Co. were consolidated in 1895, the new concern being known as the Nova Scotia Steel Co. After the purchase in 1900 of the coal and other properties of the General Mining Association, the corporation now known as the Nova Scotia Steel & Coal Co. was formed.

Merged, therefore, in the latter are the companies that mined the first coal and smelted the first steel in Canada, and being first in the field, it is in a measure but natural to expect that no effort would be spared to keep right in the van of further development and progress. That such has been the experience, the record of continuous and substantial expansion and increased earning power makes amply evident, besides indicating careful forethought in administration and planning.

The whole trend of events in the evolution of the Nova Scotia Steel & Coal Co. has been relative to, and has taken cognizance of, the two essential elements making for national industrial greatness—i.e., coal and iron. Recognition besides of the unrivalled economic locations of the various plants in the matter of tidewater facilities for reaching the markets of the world on a low freight rate basis as well as of the ease with which Canada's domestic requirements could be catered to through the medium of railroad transportation have in no less degree been a determining factor.



NEWFOUNDLAND, SHOWING LOCATION OF WABANA ORE MINES.

Steel Making at Sydney Mines

Upon acquisition of the Cape Breton coal fields, and owing to the short water carriage from their Newfoundland ore mines, the company decided it was advisable to erect a new blast furnace and open-hearth plant near their coal mines, which are situated on Sydney harbor. In 1904 a new blast furnace and open-hearth plant were put into operation at Sydney Mines. To further improve the quality of their open-hearth product, in 1911 a Harmet fluid compression plant was installed in connection with the open-hearth installation. During the same year there were also added two steam hydraulic forging presses, one of 4,000 tons and the other of 600 tons.

UNLOADING IRON ORE FROM NORTH SYDNEY SHIPPING PIER.

Car Plant Established

To take care of the increased output in the most profitable manner, and to meet the growing demand for railroad cars in Canada and elsewhere, a subsidiary company was formed in 1912. This is known as the Eastern Car Company of New Glasgow, N.S., the control of which is vested in the Nova Scotia Steel & Coal Co.

"Scotia," as the company is more familiarly called, has now become one of the largest industries in Canada, as well as a very important world factor in the production of iron and steel. Five distinct industries are combined in its operation:

1—The Iron Mines at Wabana, Newfoundland.

2—The Coal Mines at Sydney Mines, N.S.

3—The Blast Furnaces and Smelting Works at Sydney Mines, N.S.

4—The Steel Works at New Glasgow, N.S.

5—The Car Works at New Glasgow, N.S.

Wabana—Island of Iron

The Wabana (Newfoundland) iron properties are the largest on this continent, if not in the world. Available reserves of ore, as estimated by experts, are between 2,000,000,000 and 3,500,000,000 tons, an amount which at present rate of mining will not be exhausted for more than 3,000 years. By comparison with the next largest holdings on this continent, those of the United States Steel Corporation (1,300,000,000 tons), an idea of the magnitude and great wealth of this Wabana field can be formed. Equally important is the excellent quality and richness of the ore, which is a fine grade of red hematite, averaging from 51 to 55 per cent. pure iron on all three seams worked.

Only in recent years was this valuable property discovered and developed, but just how attention was first attracted to the deposits is not known. Bell Island, the site of the Wabana deposit, is some six miles long by two miles wide, and is elliptical in shape, as its name signifies.

The property in any case eventually came into the hands of Messrs. Butler of Topsail, who, after vainly endeavoring to interest other capital in the venture, finally leased the deposit to the Nova Scotia Steel Co. in 1893. Two years afterwards that company commenced to mine the ore in a small way.

The work, at first, consisted entirely of openeut mining, the earth covering being stripped off the deposit as it lay in the ground and the ore carried by an endless rope tramway to a pier on the south side of the island. This pier was nothing more than a block set out some distance from the shore and connected with it by a suspension bridge. Later, however, this was supported by a trestle.

At first the ore was used solely to supply the Ferrona blast furnace of the Nova Scotia Steel Co., and large quantities were not required. The Wabana plant, therefore, consisted merely of a hopper pier of two thousand tons capacity, and the tramway. This, however, met all the requirements, for the mining was quarry work and did not need a more elaborate outfit.

Three years later the possibility of shipping ore to European markets called for an enlargement of the plant. Storage pockets were built, giving an increase of from twelve to fifteen thousand tons storage capacity. At the same time a horizontal ore conveyor was installed, tracks were laid, and a number of other additions made.

In the year 1899, work began in earnest. Twelve hundred men were employed during that season in mining from the old property and developing the new. Tramways were constructed and a new pier built, since when the "Scotia" Company has gone ahead producing ore without a single break.

For two years after opening this new bed, the ore was secured by stripping and quarrying the deposits lying near the surface . In 1902, however, work was commenced sinking two slopes on the land areas. Operations were carried on rapidly, and, within a year, the two mines had been opened up and were being worked in a manner similar to the bore-and-pillar method of coal mining.

INTERIOR OF CHANGE HOUSE, SUBMARINE PLANT, WABANA, NFLD.

Both these slopes were sunk to a considerable height above tide-water and one of them was driven so as to come out on the shore above high water mark, thus forming an adit. The other slope, Scotia No. 2, was destined eventually to be driven under the sea.

Developing the Submarine Areas

About the year 1905 the possibilities of developing the submarine areas began to attract the attention of the "Scotia" Company. Further additions to its under-water holdings were secured, making the total of submarine property held approximately 35 square miles.

After deciding to drive a couple of slopes to the submarine fields, an arrangement was entered into with the Dominion Iron & Steel Co. for piercing their section which divided the Scotia fields. Work on this began in May, 1906, and in two and one half years the feat was accomplished, the "Scotia" Company entering its own property.

Bore-holes were sunk and proved that the same beds that out-cropped on the surface extended under the sea with an appreciable increase in the thickness of the mineral. The "Scotia" areas were entered at a distance of about 4,000 feet from the shore, and conditions were found to be more favorable than had been hoped for. Since that time the slopes have been driven a considerable distance further, and mining is now being done on a larger scale.

The under-ground excavations extend several miles beneath the sea, where electric shovels, hurrying trams and the rush of large 20-ton skips present an ever busy and noisy scene. Commingled with the deafening sound of these are the sharp rattle of air drills, the hum of modern electric pumps and the whirr of the large fans that carry fresh air to the most remote parts of the mine.

The surface equipment at the Wabana Mines consists of a deckhead and accessory hoisting engines, ventilating fans air compressor, and power generating plant.

The cars, as they come loaded from the mine, pass on to the deckhead, where they are dumped one by one in an end-revolving tipple, the ore passing over a "grizzly" and into a gyratory crusher which delivers a 4-inch ring product on to an inclined 36-inch rubber picking belt. The ore is finally delivered into a storage bin and loaded from time to time into tramline cars which carry it to the shipping pier at the south side of the Island. Direct transportation as above is made to the shipping pier in summer.

EXTERIOR OF CHANGE HOUSE, SUBMARINE PLANT, WABANA, NFLD.

Stock Piling Ore

During the winter, from January to April, when navigation is closed, the ore is stock-piled by means of a system originated and patented by engineers of the Company. The method is unique

SYDNEY HARBOR, SHOWING LOCATION OF LIMESTONE QUARRIES.

inasmuch as no trestle work is required, although at times the pile reaches a height of 75 feet. The stock-piling is accomplished through the instrumentality of a side-dump car propelled by a

TRAMWAYS AND TIPPLES, WABANA, NFLD.

main and trail rope which is driven by a single drum engine. The steel rope is led from the engine which is placed a short distance to one side of the feeding chute, to a sheave wheel some three or four hundred feet distant, thence across a second sheave wheel to the line on which it is desired to pile the ore, and down this line to the car at the chute. From the other end of the car the rope passes around a sheave wheel back to the engine. This car is of the ordinary side dump type, possessing the necessary mechanism to open the doors when engaging a stop set in the track.

The car runs on a track at an inclination of about twenty degrees, which track is kept ahead of the pile a couple of car lengths by means of a wooden frame, the lower end of which is of sufficient weight to keep the loaded car from upsetting. The only labor necessary, excepting that of an engine driver, is when it is required from time to time to move the wooden frame ahead, and even then the heavy work is performed by the engine. By this means the ore is readily handled, as fast as it comes from the mines, up to 1,500 tons per day, and at the cost of under one cent per ton.

The ore stockpiled in the winter is picked up in the busiest part of the shipping season, and sent over the tramway to the shipping pier in the already mentioned fashion.

The rehandling of this ore can be done by steam shovel or, as is the current practice with the Scotia Company, by means of a scrape or drag bucket, controlled by a wire rope passing through a sheave pulley which runs back and forth upon a suspended steel cable, one end of which is fastened upon the top of a wooden tower. This tower contains a bin of from 30 to 40 tons capacity and the necessary chutes, etc., and is supported upon wheels, thus enabling the bucket to be operated along all the radii of the circle covered by the stockpile. The drag bucket is equipped with a tripable bottom door, opened by a curved tail striking against a plate situated in the tower frame, immediately above the bin. The bucket is operated by a double-drum duplex hoisting engine of the ordinary type, and the cycle of operations may be described as follows:

The bucket is lowered to the ground at the foot of the inclined pile of ore and its latch closed. A combined hoisting and forward motion is then imparted to the bucket, its nose being thus constantly kept against the pile until load-

LOADING PIER, SHOWING CONVEYORS AT WABANA, NFLD.

ed. The engine is next reversed and the loaded bucket rapidly conveyed upon the suspended wire back to the tower, when it is automatically dumped immediately over the bins in the manner already mentioned. This accomplished, the bucket is rapidly lowered and the cycle of operations repeated.

Surface Haulage System

To transport the ore from the mines to the shipping pier situated on the south side of the island, slightly more than two miles distant, a double-track tramway operated by an endless cable is employed. The tramway is in the form of the letter "T," the head of

STOCK PILE AND DECK HEAD, SUBMARINE MINE, WABANA, NFLD.

which lies parallel and close to the outcrop of the "Scotia" ore bed, tapping the various surface pits and the mines, No. 1 to the west and No. 2 to the east of the long leg which stretches in a straight line in a southerly direction across the Island to the shipping pier. The tramway is of 2 ft. gauge and has two tracks, one for loaded cars and the other for empties. Steel rails of 28 and 18 pounds per yard are used on the respective tram tracks.

At a point located midway between the mines, where the tramway separates in three directions, and locally called the "bottom," the grades are so arranged that, by ungripping the cars, they move by gravity each in the required direction; the loaded outgoing cars falling from the east and west "full" tracks into the pier or main full track, and the empties on either the east or west toward their respective empty track on either the east or west branch for distribution to the mines.

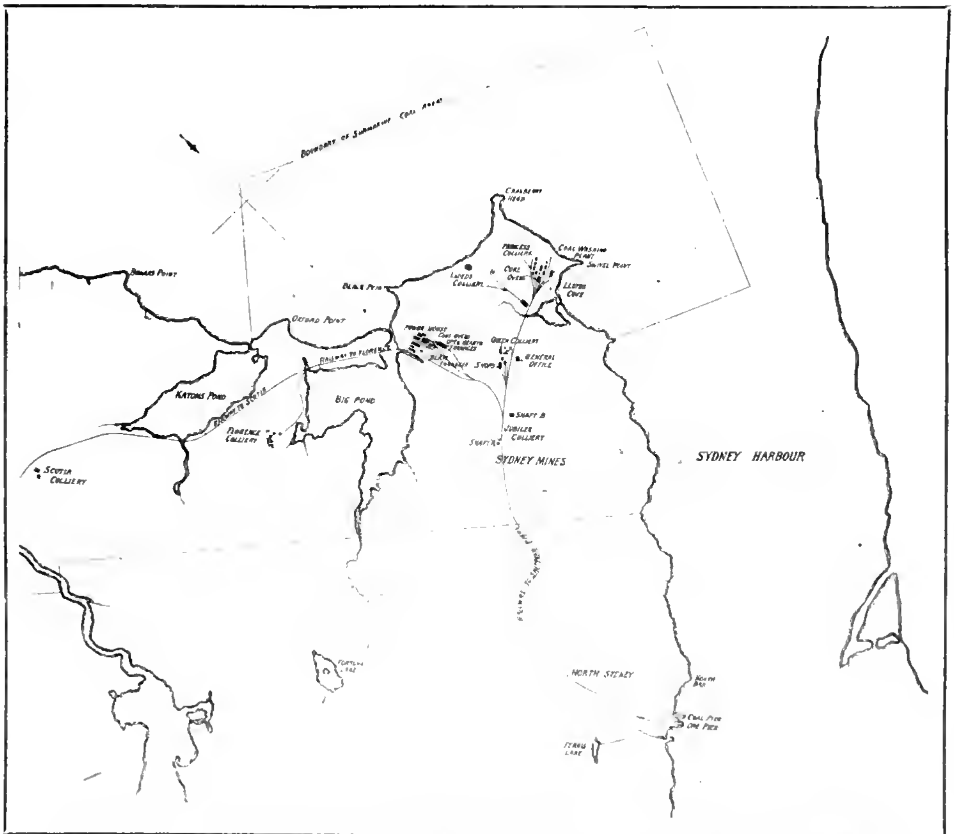
The cable of one-inch diameter "Lang Lay" plough steel, is supported upon wood rollers at short intervals, and by Hadfield cast manganese steel wheels at the crest of each rise. The cable is slightly over seven miles long, its tension being uniformly maintained by means of balance weights, placed near the haulage engine at the pier, and at the east and west extremities of the tramway. The tramway is operated by a compound condensing steam engine of 125 h.p., geared down to a driving bull-wheel to give a cable speed of 350 feet per minute. The power plant site is located alongside the shipping pier.

The cars, built of steel, have an average capacity of 1.8 tons of ore, as loaded from the chute. They are of 30 cubic ft. measurement, and are attached to the cable by means of grips, consisting of a series of levers readily operated by a plain wrench with a 30-inch handle.

ENGINE HOUSE AND DECK HEAD, SUBMARINE MINE, WABANA, NFLD.

Two of the grips, one at each end, hold the car securely to the cable upon the steepest grade on the line and may be used upon a grade up to 10 per cent.

Under existing conditions, the actual capacity of the line, allowing for all stops, is 3,000 tons per day; indeed, frequently by working overtime, the daily tonnage has been maintained at 4,000 tons per day for weeks at a time.



SHOWING LOCATION OF COLLIERIES, BLAST AND OPEN-HEARTH FURNACES. ETC., CAPE BRETON ISLAND.

Submarine Equipment

The development of the submarine areas has necessitated large additions to the equipment. A deck-head of an absolutely new type, in which the cars are handled without any horizontal landing, has been completed and is now in operation. The cars, each containing twenty tons of ore, are hauled up out of the mine by a rope one and one-eighth inches in diameter and eight thousand feet long. They dump their contents automatically, thus reducing to the minimum the number of men required to attend their operation.

The hoisting is done by a Fraser & Chalmers first motion, duplex, steam hoisting engine equipped with the most modern overwind and automatic braking devices. It is capable of considerable speed, rushing the big cars up the two-mile slope at the dizzy rate of thirty miles an hour. The cars are filled in the mine from bins, which in turn are supplied by small 2-ton mine cars.

Drilling, hoisting and pumping are all carried on through the instrumentality of compressed air. When mining was started on the land areas, two compressors were installed — a 1,200 cub. ft. capacity Norwalk machine and a 2,500 cub. ft. Norberg machine. Since then a Walker compressor of 3,500 cubic ft. capacity has been added. The pipe connections of all three machines are such that they may be operated as one plant or individually when it becomes necessary.

From April to December inclusive, two — ton cable cars transport the ore from the mine or stock-pile to the shipping piers some two miles distant. What appears like a never ending string of cars coming and going on the double track road bring their loads to tipples at a point some 250 feet above sea level.

the tipples in turn emptying the car contents into great natural gorges that have been modified to serve as receiving pockets. Two great endless chains of buckets convey the ore from the pockets to a point where it falls through chutes and automatic trimmers, a distance of 90 feet to the ship's hold underneath.

Recently there has been installed a modern electrical plant of considerable power, built on piles at the shipping pier and adjacent to the coal discharging plant. It consists of up-to-date water tube boilers and mechanical stokers, which supply steam to Belliss & Morcom vertical, forced lubrication type engines, operating Brown Boveri generators, producing 60 cycle, 3 phase current at 6,600 volts. At this voltage it is transmitted to the various points of distribution for transforming and service in both the land and submarine mine spheres of operation.

Piers

Wabana loading records, we understand, have never been equalled working under similar conditions, i.e., with a single loading chute. During the season of 1909, between April 19 and December 23, 460,000 tons were loaded in vessels at the Scotia pier in 308 loading hours. This calculation also includes the time spent in moving the vessels. therefore, the ore was loaded in ship's hold at the average rate of 1,500 tons per hour. On numerous occasions this rate has been very considerably increas-

NORTH SYDNEY SHIPPING PIER FROM ELEVATED TRACKS.

ed on single vessels, a rate of over 2,200 tons per hour having been attained on a 7,000-ton ship. These figures apply of course to loading through a single chute. Since 1913, when the east pier was put into service, the time of loading has been cut almost in half, and ships of the company carrying 12,500 tons each have been fully loaded in 3½ hours.

Power Dock

Immediately to the west of the pier from which the ore is shipped there is a large wharf for receiving incoming supplies, etc., and here is located a modern steam driven coal gantry for economically handling coal to operate the plant and to bunker ore steamers with despatch when coal is required by them. This apparatus can be operated by a single man and has a capacity of 1,000 tons per ten-hour day continuously.

Welfare Work

About 500 men are employed in and about the mines at Wabana, and for their accommodation there have been erected a large number of houses which are rented at a low monthly rate. The property of the "Scotia" company surrounding the plant is attractively laid out in streets and building lots, and West Wabana is rapidly becoming a town of considerable size and importance. A water system for fire and domestic supply purposes has been installed.

For the proper care and treatment of sick and injured, there has been built and equipped a small hospital. A well stocked dispensary and the necessary instruments and apparatus found in any well appointed institution of the kind are provided; also, the work in connection with it is in the care of a competent physician and nurse. Every man subscribes a small monthly fee for hospital purposes, this providing him with free medical treatment in case of sickness or injury. First aid boxes are placed at various points on the plant surface and underground for rendering prompt assistance to the injured.

PRINCESS COLLIERY, SHOWING SURFACE EQUIPMENT AT SYDNEY MINES.

The duty of providing safety arrangements and appliances about the workings is in the hands of a committee of the staff, who make weekly visits to different parts of the plant, and by study, recommendations, and regulations they seek to obtain the greatest immunity from accident and personal injury in all departments of the work from blasting to operation of machinery, tramming, etc. A large clean concrete change house has been built at a convenient point on the surface, where in a warm, well-lighted room, supplied with hot and cold water, the men may change their clothes, wash, or bath. Underground, large clean and well lighted lunch rooms are maintained, and hot

POURING 3-TON INGOTS, SYDNEY MINES.

and cold drinking water are supplied for the use of the workmen there.

Summary

The Wabana mine is to all appearances one of the largest deposits of iron ore of proven value at present operated anywhere. It consists of several beds occurring in a rock basin of large area, the greatest part of which extends under Conception Bay, Nfld., but outcrops upon the north shore of Bell Island. The deposit has now been worked continuously for twenty years, the production of ore increasing gradually from year to year until 1913, when the output amounted to over one-and-a-half million tons.

Notwithstanding that all the necessary facilities for efficient mining operations have been developed and utilized, further extensive additions and equipment of the most modern type are being installed to provide not only for the comfortable maintenance of the present output but for its early substantial increase in every direction.

From the land areas, over 12½ million tons have been mined to date. The submarine areas have been developed by means of slopes driven 7,300 feet out under the waters of Conception Bay, and the ore has been found to be fully maintained both in quality and quantity in this territory. No conditions have so far been met to affect adversely efficient and economical mining operations.

Sufficient ore has been developed in the submarine areas alone, over three-quarters of a million tons of ore having already been extracted, to assure an annual output of one million tons from this section uninterruptedly and for very many years to come.

The situation of the deposit on a comparatively small island in the Atlantic Ocean is ideal and unique, affording as it does the choice of catering to either or both European and American Continental markets. One half million tons of ore per year are sold in the United States and Europe, the remainder of the output being shipped to the company's furnaces at Sydney Mines, N.S.

A glance at the map of the world which appears on another page of this issue will indicate clearly the strategic location of the Wabana iron mines relative to all important home and foreign markets. The mines are almost directly on the route of North Atlantic shipping. The "Scotia" Company sells some half million tons of ore each year to Canada.

OPEN-HEARTH FURNACES AND CHARGING MACHINE, SYDNEY MINES.

SLAGGING BLAST FURNACE AT SYDNEY MINES

the United States and Europe, the balance of that mined being, as we have already seen shipped to its blast furnaces at Sydney Mines, N.S., for conversion into steel, and as such to its steel plant in New Glasgow, by rail, for conversion into finished and semi-finished steel products which in due course find their way to practically every corner of the civilized world.

Limestone Quarries

Limestone being an important accessory in blast furnace operation, it was absolutely essential that an adequate supply be both convenient to the steel-making installation and readily available. Nature again had made bountiful provision for successfully prosecuting the manufacture of steel in this respect.

At Point Edward, some nine miles distant from Sydney Mines, and connected with the main line of the Intercolonial Railway by a branch line 2½ miles long, limestone in quantity was discovered, and following the usual survey and investigation, a property of about 250 acres in extent containing carboniferous stone in layers, high grade and uniform in quality was acquired. The product here is got by quarrying, a Lidgerwood overhead cableway with two towers and radius of 800 feet being installed in connection with the latter. The limestone is mined on the open cut system, there being little top soil to remove, and as it is brought direct to the blast furnace from the quarry in railway cars, an abundant supply at a very low cost is readily at hand for smelting purposes at the Sydney Mines plant, or elsewhere.

QUEEN PIT AND ENGINE ROUND HOUSE, SYDNEY MINES.

Coal Areas

The estimated content of the Cape Breton coal properties of the Nova Scotia Steel & Coal Co. run to over 2,500,000 tons, and in addition to ranking high as company assets are among the most important holdings of their kind in Canada. For steam, metallurgical and general purposes, the coal recovered at Sydney Mines is highly regarded, being both comparatively pure and of high calorific value.

Four different coal areas are owned, these being known as the Sydney Mines Land, Sydney Mines Submarine, Boulardarie Land, and the Outer Submarine. The first three run continuously from the north side of Sydney harbor to the south side of the Great Bras d'Or, a distance of some ten miles or thereby.

The Outer Submarine areas extend from Cape Dauphin to Cape Percy, covering the entire Cape Breton coalfield, and, within their contained 21 square miles there is believed to exist every known seam in this already well - proven Sydney Mines district.

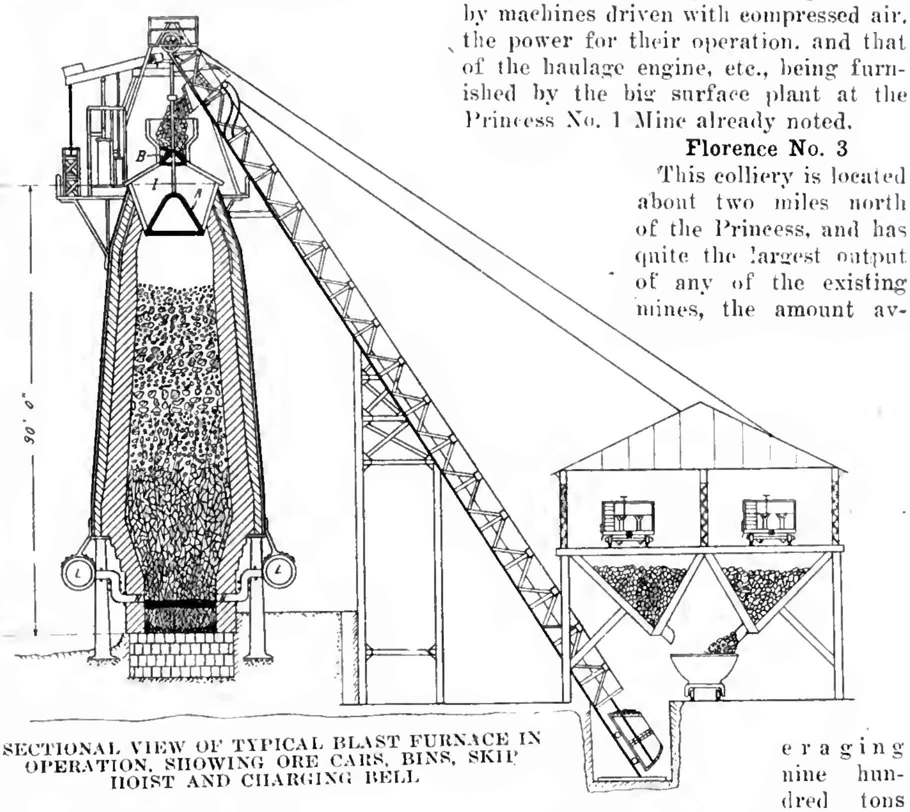
A comparatively small portion of these areas has been worked in the ninety years that mining has been carried on, operations having been confined almost entirely to the southern part of the Sydney Mines Land and Submarine Areas. Collieries have been opened in the central portion of that district only within the last four or five years, while as yet not a pound of coal had been taken from the Northern, the Boulardarie or the Outer Submarine fields.

The thickness of the coal in the various mines runs from five to six and a half feet, the dip being uniformly about eight per cent. The coal is largely mined by the bore and pillar method, but different systems of mining, pumping, haulage and ventilation are practised at the different mines to meet special or local conditions.

Since the Nova Scotia Steel & Coal Co. took over these properties much development has taken place at Sydney Mines. Where, in 1900, one colliery was in operation, with an annual output of

GENERAL VIEW FROM OFFICE OF STEEL PLANT AT SYDNEY MINES.

240,000 tons, to-day five well equipped mines are producing about 900,000 tons, and during the present year a new colliery will be adding 360,000 tons to the already substantial yearly output.



SECTIONAL VIEW OF TYPICAL BLAST FURNACE IN OPERATION, SHOWING ORE CARS, BINS, SKIP HOIST AND CHARGING BELL

At Sydney Mines there is also a modern steel plant, described later, with blast furnace and open-hearth steel capacity of about 100,000 tons per year, equipped with all the necessary coke ovens, coal washers and engineering shops. The railway system has been practically rebuilt and greatly extended, while at the shipping port of North Sydney, only three miles from the collieries and steel works, extensive docks, with the most modern facilities for coal shipping and ore receiving, have been constructed. This development has given new life to the sister towns of Sydney Mines and North Sydney, so much so that they have become two of the most important industrial centres in the Maritime Provinces. A brief description of the colleries now in operation follows:

Princess No. 1

This colliery was the only one in existence when "Scotia" took over the property from the General Mining Association in 1900. The coal cutting is done by hand. About six hundred men are employed underground, and the mine is equipped to maintain an average daily output of eight hundred tons. The surface plant is the most extensive of any of the collieries, being used as a central plant for many of the operations of Mines No. 2 and 5. Half the boilers at this plant burn waste gases from the nearby coke ovens and the remainder are fired with refuse stock from the coal washing plant, which is referred to later.

Lloyds No. 2

The capacity of this colliery is six hundred tons per day. Cutting is done by machines driven with compressed air, the power for their operation, and that of the haulage engine, etc., being furnished by the big surface plant at the Princess No. 1 Mine already noted.

Florence No. 3

This colliery is located about two miles north of the Princess, and has quite the largest output of any of the existing mines, the amount averaging nine hundred tons daily. Five hundred and fifty men are employed. Six 240 h.p. Stirling boilers supply steam for the different engines, and are equipped with forced draught fans to facilitate the burning of the fuel, which consists principally of waste from the coal washer.

Scotia No. 4

This is considered one of the most interesting mines on the Continent, not because of its size, but because of its being operated underground wholly by electricity. The cutting and handling of coal and the pumping of water is all done electrically. It is claimed to be the only colliery in Canada in which mechanical appliances are utilized to the utmost, although it does not contain a single steam or air pipe. The daily output of nine hundred tons is secured with a minimum of capital outlay and with low overhead charges.

Queen No. 5

This mine was opened up and first operated by the General Mining Association. It was one of the best producers at that time and was more familiarly known as "Queen Pit." The haulage system is now operated by electricity and its equipment is modern in every way. Its capacity is five hundred tons per day the year round.

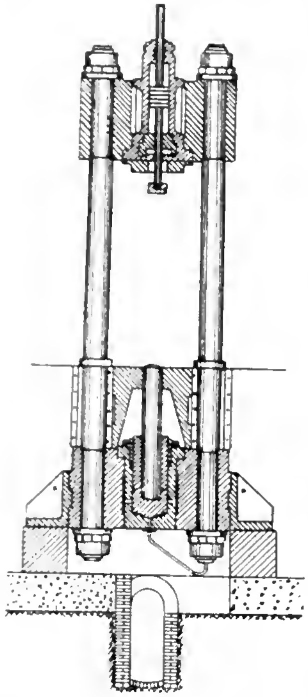
Jubilee No. 6

This is a new mine being opened up. It will have the largest capacity of the "Scotia" group, as its output will amount to about 1,500 tons per day. The shaft which was started in 1914 is now nearly finished, and other preparations are being made for commencement of operations during the present year.

In the three latest collieries to be operated the underground haulage, or method of conveying the coal from the working places to the main haulage of the mine, is performed by small engines, driven in one colliery by electricity and in the other two collieries by compress-

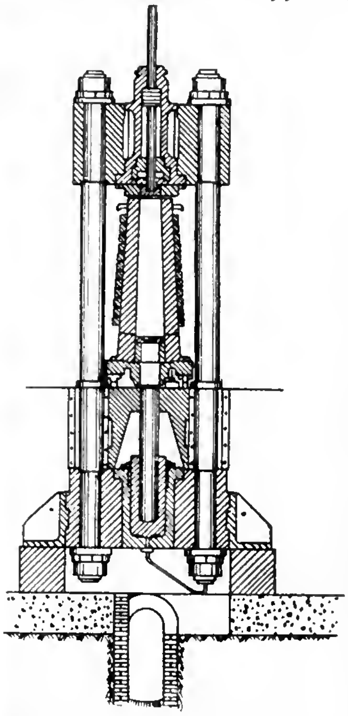
COKE OVENS SHOWING A "DRAW" IN FOREGROUND, SYDNEY MINES.

ed air. Not a single horse is employed underground in either of these three collieries (Nos. 2, 3 and 4), and no horses will be employed in the new Jubilee Colliery. This is an unusual condition of underground coal mining; either horses or ponies being used in nearly every coal mine. The adoption of electricity by "Scotia" on a large scale is the result of the thorough and satisfactory trial which has been given to this motive power. The Jubilee mine is to be operated altogether by it, both on the surface and underground.



HARMET PRESS. MOLD NOT IN POSITION.

POURING 6-TON INGOTS, SYDNEY MINES.



HARMET PRESS, MOLD IN POSITION.

All the coal mined from these collieries is screened as it is raised, and, of the output, 75 per cent. of merchantable coal is shipped by rail and water to the various markets, while the remaining 25 per cent. is washed and converted into coke for metallurgical pur-

POWER HOUSE, BLAST FURNACE, COKE OVENS, ETC., SYDNEY MINES

poses. The refuse from the washing plant is conveyed automatically to the colliery boilers.

Coal Washing Plant

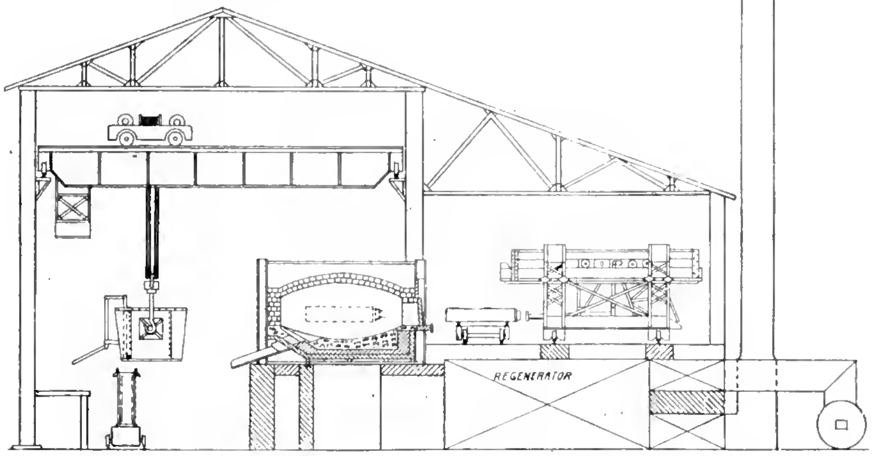
The construction of this plant was begun in June, 1913, and completed in the autumn of 1914. The washer is of the Baum type, the general arrangement of the plant being designed by Messrs. Simon-Carves, Manchester, England. It has a washing capacity of 1,000 tons of fine coal in ten hours. In general, it consists of a reinforced concrete building elevated about eighteen feet above the yard level and supported by reinforced concrete columns. Ahead of the building and under the tracks is a large pocket into which the raw slack coal is dumped from the railway car, after having first passed over a pair of two hundred ton track scales.

Alongside of the washery building is an elevated settling tank built of reinforced concrete and designed to hold 150,000 gallons of water, the water tank being protected on the outside by a suitable enclosure which provides sufficient air space to prevent freezing.

In the usual operation of this plant, the raw slack coal is dumped from either of two tracks into the elevator pit, and from there the coal is fed to a bucket elevator which delivers it to the large wash box on the upper floor of the building. Here all the coal is washed, no further treatment being necessary for the larger sizes, although the smaller sizes are rewashed and passed over a system of screens. The larger sizes are delivered by a series of bunker pockets to the crushers, while the smaller sizes are passed along to another washing box and rewashed. In the process of washing, the heavy slate and dirt eventually sink to the bottom of the box and are removed automatically by a spiral conveyor and elevator. This dirt is finally collected in a storage bin or is dropped through a cast iron pipe in which flows a stream of water that flushes the refuse material to the sea.

The purpose of the plant is to remove as far as possible all slate and sulphur from the coal. It is also essential to keep coal from being carried away with the refuse material. To reduce the waste to a minimum, a third or middle product is made by varying which the loss of coal becomes very slight and the quality of the washed product considerably improved.

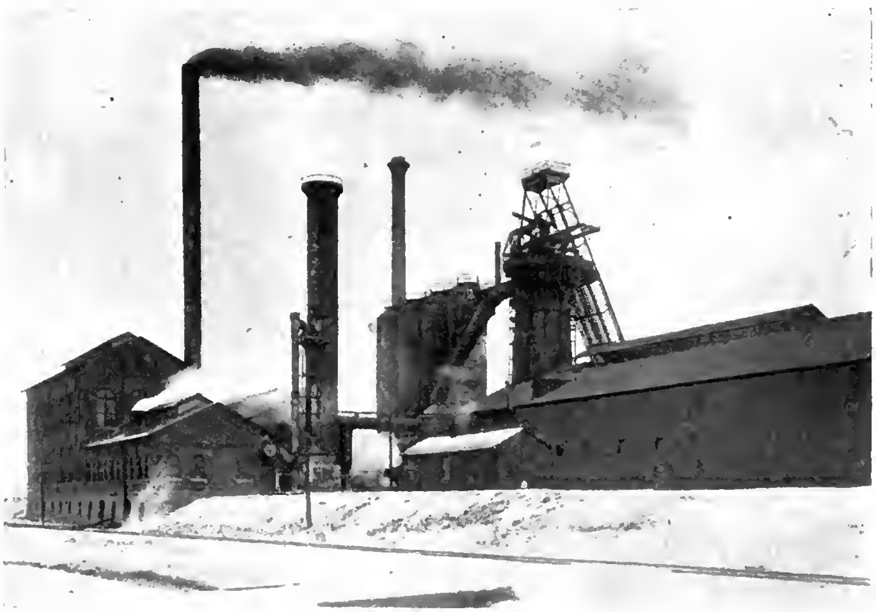
After the coal is washed, the larger sizes are divided into two grades of nut coal and may be shipped separately, or they may be again mixed and passed through a pair of rotary crushers and reduced to sizes sufficiently small for coking purposes. After passing through the crushers the coal is mixed with the fine slack and taken by a twenty-inch conveying belt to the storage tower near the coke ovens. The middle product coal, after being collected in a storage pocket, is transferred to a 16-inch belt conveyor, which carries it to the boiler-house, where it is weighed and distributed to pockets for use as fuel. The water used for washing the coal is collected in a drainage tank where it is clarified and used over again, the settlings being easily removed through a valve at the bottom.



SECTION OF TYPICAL OPEN- HEARTH FURNACE BUILDING.

Coke Ovens

The washed coal is at once conveyed into the neighboring coke ovens. These have been continuously improved and added to, so that at present they consist of 30 Bauer ovens at Princess Colliery, and 120 Bernard ovens, the total capacity of the united batteries being 300 tons of coke per day, all of which is used by the company for smelting purposes.



BLOWING ENGINE AND BOILER HOUSE, STOVES, BLAST FURNACE HOUSE AND EXTERIOR EQUIPMENT.

These latter ovens are situated convenient to the blast furnace, where the coke is consumed, so that after the coke is produced there is only one handling of it, and thus much breakage and waste is avoided; an important consideration.

Coal Handling Plants

At North Sydney are situated the coal loading and ore discharging piers. There are two coal piers, high and low level. The former is 60 feet above high water and is 1,000 feet long, including approaches. It is equipped with bins to hold 5,000 tons. Seven thousand tons have been handled over this pier in six hours.

The low level pier is thirty-four feet above high water, and has a length of 1,300 feet. This is used principally for loading small craft and for bunkering.

The company also possesses extensive docks at Quebec and Montreal. The Quebec plant consists of three gantry cranes situated on the Louise Basin, which discharge on the stock piles or into cars or lighters without further handling. The plant has a capacity of 3,000 tons per day.

the steel mill and forging plant at New Glasgow for final conversion into finished and semi-finished products to both home and foreign order

Fluid Compressed Steel Plant

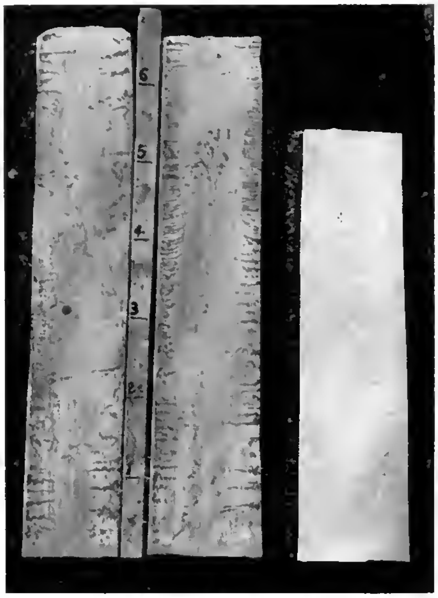
The chief additions made to the steel making plant at Sydney Mines since its initial service installation in 1905 may rightfully be stated as those connected with the installation of a complete equipment for the production of "fluid compressed" steel on the Harmet process. The open hearth furnace capacity with its contributary requirements has however also been increased.

By way of introduction, it may be stated that what is known as the Harmet process of making "fluid compressed" steel consists in submitting the ingot immediately after pouring, and while the metal is still plastic to intensive yet carefully calculated compression from all sides in a conical mold during the cooling period, the aim being to prevent the formation of pipe, blow holes, undue localized segregation or internal strains: in short to make the metal throughout the entire ingot homogeneous.

O. H. Ingot Defects

For many years much time has been given and research work undertaken relative to basic open-hearth steel, and many forms of treatment have been devised as a result, whereby its quality may be improved by eliminating defects inherent to and arising from its manufacture during different stages of the latter. Of the defects referred to, unsoundness of the cast ingot to a lesser or greater extent is easily the most serious. Varying degrees of success have been achieved by different methods of treatment, and not the least effective in the direction indicated has been that of the Harmet Fluid Compressed Steel Process.

The Nova Scotia Steel & Coal Co., realizing the importance of "fluid compression," as a valuable aid in manufacturing reliable and high class steel products, procured by purchase the Canadian license from M. Harmet, of St. Etienne, France, whereby they own the sole rights in this country to use his process. This they considered to be strictly in accordance with their policy of taking advantage of every important metallurgical development, thus advancing with modern progress; and particularly that their already well-known reputation as manufacturers of first quality marine, railway and general machinery forgings should be both maintained and enhanced.



A B C

SAWN INGOTS, A AND B, AS ORDINARILY CAST, AND C, MANUFACTURED BY HARMET PROCESS.

Note surface and other blow holes in A and B, also tendency to pipe in the latter, and absence of both in C.

INGOT STRIPPING YARD, SYDNEY MINES

The installation of the Harmet Fluid Compressed Steel Plant at Sydney Mines was made in 1912, however before entering into a detail description of the equipment, its operation and product, it may be well to point out a few facts concerning the ideals aimed at and being consummated by this and other somewhat similar processes. A generally held opinion and one too often carelessly expressed refers to steel as such being liable to unaccountable failures. For most purposes as against iron, even in spite of occasional and unaccountable failures, it has easily shown its superiority, and where it has fallen down there has simply been given additional impetus to research and improved methods of production.

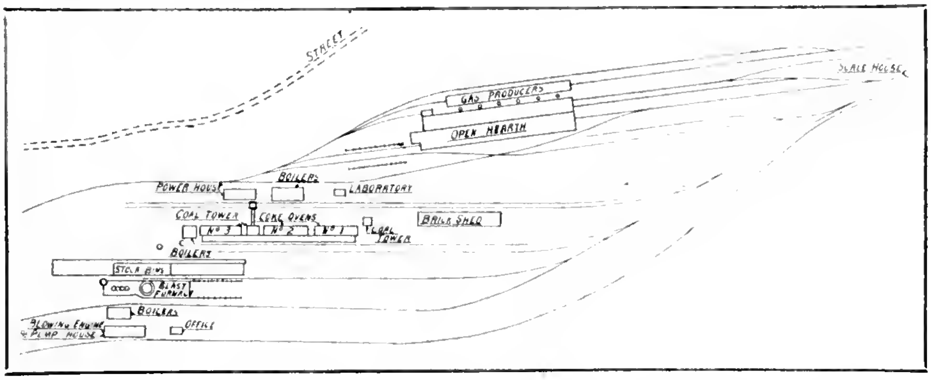
To not all steel manufacturers, however, does the latter statement apply, because for ordinary purposes, the usual merchant brands of steel are satisfactory and the cost of extra treatment would be prohibitive. Those who are placing on the market high grade steel for heavy forging purposes are however, applying the method known as the Fluid Compression Process, by which the metal is subjected to high pressure while passing from the molten to the solid state. The product of this process is used in the manufacture of first quality forgings, such as locomotive axles, crank shafts, marine forgings, artillery tubes and armor plate of the highest grade; in fact, for all articles in which maximum reliability and homogeneity of structure are demanded.

The defects most common in steel cast in ingot molds are:—Blowholes, pipes, porosities, cracks, internal stresses, segregation, and excessive crystallization. Blowholes are caused by the presence of occluded gases in the liquid metal. Iron, like water, has a higher solvent power for gases, such as carbon, monoxide, nitrogen and hydrogen, when liquid than when solid. Thus, during the solidification of the steel, the excess gas dissolved when the metal was liquid is expelled, and, becoming entangled in the hardening mass, causes bubbles or blowholes. These may either be deep-seated or located close to the surface. While both are highly undesirable, the latter are particularly so.

Ordinarily, deep-seated blowholes close up upon rolling or forging, and probably do little harm if sufficient work is done upon the metal, but in the case of large sections the necessary amount of work to effect this is seldom given. The blowholes which occur close to the surface are liable, while the ingot is being rolled or forged, to burst, thus caus-

ing a break, through which atmospheric oxygen and slag may enter the cavity. Should oxygen do so, it reacts with the iron of the interior wall of the blowhole, forming iron oxide, the presence of which effectually prevents welding and leaves a permanent flaw. To surface stresses are also set up in a similar fashion, due to the contraction of the metal, and these rend the metal with small fissures or cracks, which further increase the porosity of the central part of the ingot.

Segregation, or the unequal distribu-



LAYOUT OF BLAST FURNACE AND OPEN-HEARTH STEEL PLANT AT SYDNEY MINES.

blowholes are due, therefore, most of the surface cracks frequently found on turning up steel pieces.

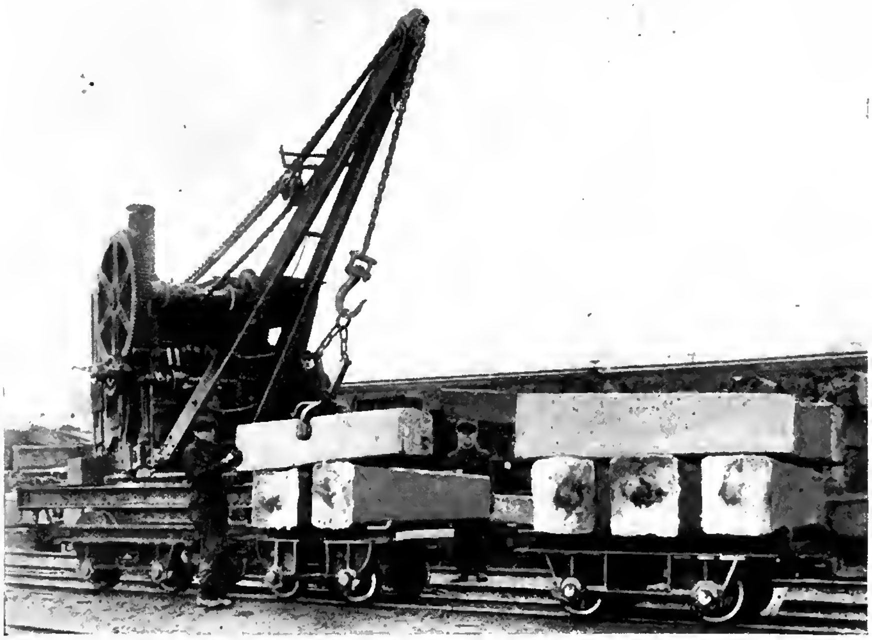
The "pipe" or central cavity is due to shrinkage, and is distinguished by an opening or void, usually found most highly developed near the top and toward the centre of the ingot. The same cause—shrinkage—produces a continuation of this defect downward along the longitudinal axis, the visible pipe gradually tapering away until its presence is only marked by the spongy or porous structure of the affected metal. If the ingot is allowed to cool undisturbed in the mold, this pipe, including the lower porous section, cannot well be avoided.

In cooling a freshly poured ingot, the outer crust of the steel first becomes rigid, and thus determines its outer dimensions. The greater part of the contraction has already taken place in the metal forming this shell, but there still remains the interior liquid, the volume of which is greatly modified by shrinkage during cooling. Little by little this molten metal becomes plastic, and, attaching itself progressively to the solid shell, adds to its thickness, and tends to leave a hollow portion or cavity equal in volume to that of the shrinkage of the metal. Simultaneously there is a tendency for the more fluid metal from the hotter portion of the ingot to flow in and fill up this area. The visible "pipe" is, therefore, caused by the gradual descent of the still liquid metal to fill up the void due to shrinkage.

Again, the shrinkage continues after solidification, and, as the metal of the outer shell of the ingot is colder and more solid than that toward the centre, therefore, the inevitable contraction accompanying cooling is made possible only by the growth of minute voids, thus causing a porous structure along the lower part of the central axis. Internal

tion of impurities throughout the ingot, is chiefly due to the melting points of these constituents being lower than that of iron. The cooling of the outer portions of the ingot causes a flow of these impurities to the more molten metal of the interior. The central and upper portions, being the last to solidify, thus show the greatest degree of segregation.

The effects of the presence of these different imperfections are important, and demand great care and attention in order to prevent serious defects in the finished product. If the ingot is allowed to cool freely, the formation of either the visible pipe or blowhole may be



LOADING 3½-TON INGOTS FOR COGGING MILL.

somewhat controlled, but both cannot be avoided, while the invisible effects accompanying the pipe, described as sponginess, segregation, and internal stresses, cannot well be prevented unless by some such process as is the subject of this description.

In producing steel for all ordinary purposes, the manufacturer cuts off the upper part of the ingot and discards it, thus avoiding the portions of the ingot most affected by the defects described. Where utmost reliability is essential, further efforts are made to minimize the injurious influence of defects by increasing the proportion of discard and by hollow-boring the ingot.

The discard, being of inferior quality, is utilized in the manufacture of low grade material, or is scrapped, a large percentage being fit only for the latter purpose. It will be noticed that by cropping and similar methods, no improvement in the quality of the material is attempted, but only a selection made of the most uniform portions of the ingot. It is apparent that this method of obtaining uniformity, besides being ineffective and uncertain, is also very expensive. Thus there is a strong incentive to crop as little of the top of the ingot as possible: hence much unsound steel. All the above irregularities in composition and in structure of steel are ultimately due to three forces, namely: crystallization, shrinkage and segregation, and the trouble developes during that period in which the liquid metal passes through the so-called solid solution stage into the stable solid state, or, in short, while it cools.

Whitworth System

Owing to the natural difficulties in the way, such as high temperature and weight of the mass to be handled, and the troublesome forces to be controlled, little was done to solve the problem of preventing the formation of defects accompanying solidification, until about

1865, when Sir Joseph Whitworth undertook the task. The solution which suggested itself to him was to submit solidifying steel to great pressure. This would force some, if not all, of the occluded gases to exude, reduce the blowholes to insignificant dimensions, and also would prevent the formation of pipes. Further, by equalizing the pressure throughout the mass, a more homogenous steel, both physically and chemically, would be obtained. The Whitworth process consisted, in brief, of subjecting the fluid steel, which had been poured into a side-strengthened cylindrical mold, to a pressure of above two tons per square inch, and preferably six tons or more, and continuing same throughout the cooling period of the metal. It was found when this pressure was applied that large volumes of gas were driven off, and the ingot shortened—rapidly at first, but later on more slowly: the entire shortening amounting to about eight to ten per cent. more than when cooled in the ordinary manner.

The objection to this process is its initial and operating cost, and its inefficiency, the latter due to the fact that the pressure is applied only at the top of the ingot. The effect is that the great force of the pressure is applied only in the walls of the ingot., which, in cooling rapidly, forms a crust with the rigidity of a column, thus arresting the force applied, and protecting the molten central portion from pressure. Thus, to accomplish compression, the maximum amount of energy appears necessary of application. There would also seem to be a tendency of the pressure in the Whitworth process to make ingots open up in a manner similar to the staves of a barrel, and to force the rich, segregated liquid from the interior into the cavities thus made. The improvement in the quality of steel subjected to this treatment is marked and very important nevertheless.

The Harmet process main objective is not so much to remedy the already-mentioned and other metal defects as to forestall their development. The process can be described briefly by saying that the ingot, immediately after pouring, and while still fluid, is lifted from below and pressed into a mold of diminished cross-sectional areas. The pressing is stopped only after the steel is chilled. The slightly conical form of the mold causes the pressure on the base to produce lateral compression, and with great effectiveness, due to the wedge-like action. The ingot is thus put under intense compression, transversely and longitudinally, with a relatively small expenditure of power.

The forces of this method of "Wire-Drawing," acting on the lateral surfaces or walls of the mass, as well as on the ends, cause these walls to be crushed inward to diminish the volume, and the work performed is found to be proportional to the total diminution in volume of the metal, or to the contraction for each pound of metal. This work has been found to be constant per unit of weight for steel of any definite chemical composition. It will be seen that the Harmet process possesses at least the advantages of the Whitworth press, while chief objections to fluid compression, as carried out by that method, are eliminated. The advantages claimed from the Harmet treatment, and substantiated in practice, are:

1.—Prevention of cracks due to shrinkage; prevention of internal stresses and resulting cracks or fissures.

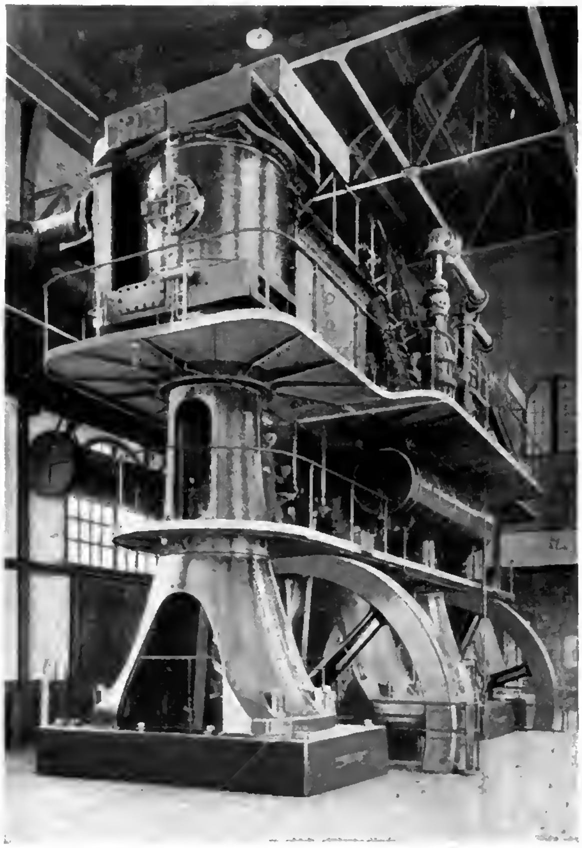
2.—Early cessation in the crystallization of the metal, as pressure hastens the transition from the liquid to the solid state; the production of fine crystallization without cleavage planes.

3.—Lessening of segregation, i.e.: reduction of tendency of carbon and other impurities to concentrate in the central and upper parts of the ingot. The gradual movement of the ingot upward into the cooler portion of the mold adds to this tendency.

4.—Prevention of "pipes" or interior cavities, due to the lateral pressure, and thus preservation of absolute solidity in the ingot.

5.—Improvement in physical properties, due to the mechanical effect of the operation being similar to forging.

6.—Reduction in the waste of ingot, practically no cropping being necessary, as the uniformity of composition and absence of cavities is maintained throughout the whole of the ingot.



"SOUTHWARK" BLAST FURNACE BLOWING ENGINES, SYDNEY MINES.

Fluid Steel Compression Plant Detail

The fluid compression plant installed at Sydney Mines consists of one group of Harmet presses each of 1,250 tons for handling four ingots of from 2½ to 5 tons weight at one time, and a 4,000 ton Harmet press for handling ingots of 12, 20 and 30 tons. The presses with their equipment of pumps, accumulators, operating valves, etc., are erected in an extension to the open-hearth buildings, situated close to the furnaces there, and arranged so that the pouring ladle containing the metal to be compressed has, as it comes directly from the furnaces, only a short distance to go to the pouring platform. The press proper consists of two hydraulic cylinders with actuating pistons, having at their ends rams which fit loosely the inside of the top and bottom of the ingot-mold respectively. The cylinders are held a certain fixed distance apart to allow the ingot mold to be introduced between them, when the rams are withdrawn. This is effected by heavy tie-rods, which are fastened to lugs upon the cylinders.

The ingot-molds are of cast iron, tapered, and strongly reinforced with steel bands to resist great pressure. They stand upon heavy movable cast-steel buggies, through the floor of which a short shaft transmits the pressure as received from the lower ram piston, imparting it to the bottom of the ingot. The upper ram is brought directly in contact with the metal at the top of the ingot, and merely acts as a buffer to the bottom ram which supplies the power for the actual compressing. The upper ram is slightly withdrawn from time to time as the ingot is pushed further into the mold. The mold buggies are movable and run on a horizontal track which extends sufficiently far on either side of the presses proper to give plenty of standage room.

In the case of the group press there is standage room for a train of four moulds quite clear of the presses. The buggies are hauled along the track by means of a hydraulic-operated conveyor until the correct position under the press is reached. Here it is securely held by

means of similarly actuated stops which come up through the floor. The pouring platform, upon which the ladle and stopper men stand when pouring the heat, is situated at the side of this track, slightly removed from the presses.

The empty mold is placed on its movable buggy, and when the metal is ready to be poured, is moved to a position immediately next the pouring platform. As soon as the mold is filled with metal it is propelled into position under the press. Each of the group molds is poured successively and the process proper commenced on each as soon as it is in position under the press.

Once this position is attained, a water spray is turned on to cool the top of the ingot in order that the metal may not adhere to the ram. The top ram is then let fall to come in contact with the metal. The bottom ram is next brought into service, a pressure gradually increasing up to over three tons per square inch of ingot bottom area being employed. The total pressure upon the ingot, in the case of 3-ton size amounts to 1,250 tons. The length of time before a full pressure is reached depends upon the size of the ingot, and may be taken as fifteen minutes for each ton of metal, or, say, forty-five minutes for a three-ton ingot. This maximum pressure is maintained for another fifteen minutes per ton of metal, thus bringing the total time under press for these conditions to one hour and a half.

Connected with each of the press rams is a system of cords leading to and operating a pencil moving over the surface of a constantly rotated cylindrical drum. The vertical movements of the pencil are proportional to those of the ram and show the longitudinal shrinkage of the ingot. Thus a continuous time-displacement curve is obtained for the compression period. The pressure upon the cylinders may be read directly from pressure gauges situated with the hydraulic controlling valves in front of the above-mentioned drums, upon the press operator's platform.

It has been found that in order to obtain the best quality of steel from ingots of certain size, form and composition, a definite curve must be followed, and once such a curve is obtained it is only necessary to cause the pencil or pointer to follow it in order to reproduce the same condition.

When the compression is finished, the bottom ram is withdrawn, and the top ram brought into play, thus stripping the ingot. The mold is then removed in the ordinary way and the ingot taken to the ingot yard. Ingots of 5 tons and upwards treated by the above plant are used solely for making heavy forgings at the company's steam-hydraulic forging plant at New Glasgow. From tests conducted on uncompressed and fluid compressed steel at the Sydney Mines plant, the results were such as to amply justify the claims already made for the Harmet process of manufacture as being superior in every feature where forging ingots of homogeneous structure and maximum reliability are called for.

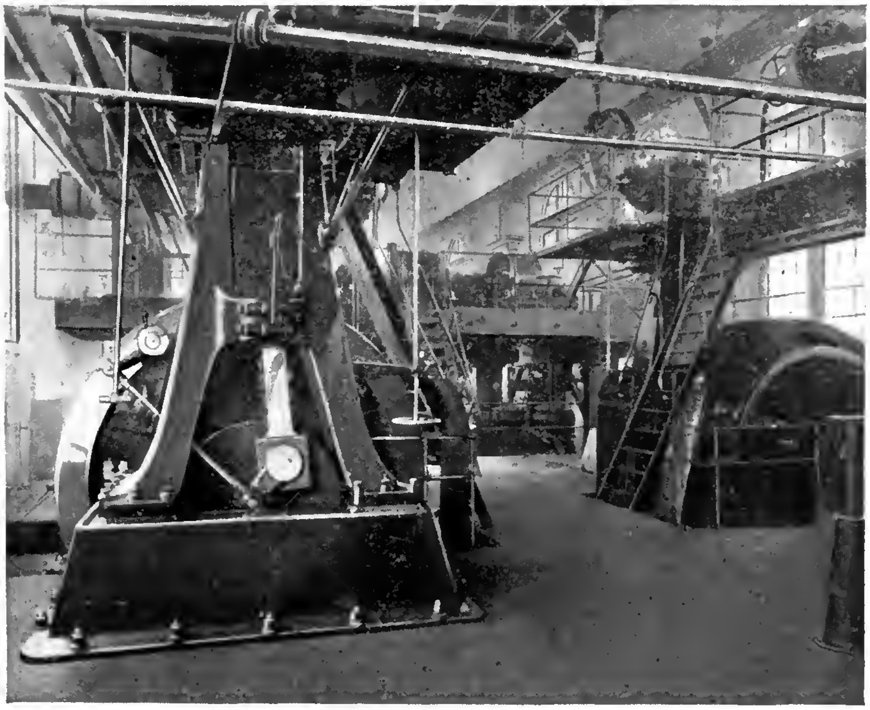
MAJOR C. L. CANTLEY,
Asst. Gen. Manager and Ordnance Adviser.

Miscellaneous Equipment Data

Coal Washer—The washed coal from the Washer plant is delivered on a Robins conveyor belt to the coke ovens storage tank, and the "middles" or boiler coal is delivered on a similar belt to the colliery boilers. The outstanding features of this plant are as follows:—The washed product before leaving the Washer is dried by natural drainage in the draining band down to eight per cent. moisture. There is also an ingenious device for the recovery of the fine floatings which are ordinarily lost. The last operation is the pulverizing of the coal, insuring thorough mixture; and the fact that all metallic substances are removed in the first washing box avoids the possibility of damage to the mechanism, which is incidental to the washing machinery in plants where the crushing is the first operation.

Coke Ovens—One battery of coke ovens in the vicinity of the Coal Washer Plant, of the Bauer retort type, is 38 ft. long, 7 ft. high, and 20-22 inches wide. The waste gases from these ovens are used to generate steam at Princess Colliery. The ovens are charged from the top, and the coke pushed by a steam-driven ram-type pusher. There are also three batteries of 40 ovens each—120 altogether—of Bernard retort type, their dimensions being 32 ft. long, 5 ft. 8 in. high, and 21-23 inches wide. The waste gases are used to generate steam for the electric power plant. Ovens are charged from the top, and coke is pushed by electrically-operated pushers.

Central Power Plant—The power plant is operated by three Stirling water-tube boilers, of 310 h.p. each, working at 200 lbs. pressure, with 100 degrees of superheat, together with nine fire-tube boilers, by Mathieson, New Glasgow, fired with waste heat from the ovens, working at 150 lbs. pressure, and developing approximately 100 h.p. each. The engine-room equipment consists of two 400 k.w. Canadian General Electric 250-volt, direct current generators, connected to two 18-in. and 36-in. diameter cylinders by 24-in. stroke vertical cross compound con-



POWER PLANT INTERIOR, SHOWING STEAM ENGINE AND STEAM TURBINE DRIVEN ELECTRIC GENERATORS, SYDNEY MINES.

densing Robb engines, running at 150 r.p.m. At present these engines are running non-condensing; the exhaust going to a mixed pressure 750 k.w. turbine of the Rateau multicellular type. There is also a 200 k.w. Canadian Westinghouse 220-volt, 3-phase, 60-cycle, motor-driven alternator. The 750 k.w. mixed pressure turbine is driven from three above-mentioned Stirling water-tube boilers, fired with the waste gases from coke ovens. A 2,000 k.w. steam tubine, to be connected to a 2,000 k.w., 3-phase, 60-cycle, 2,200-volt alternator, with surface condensing equipment, is now in course of construction.

Blast Furnace—The power equipment for the blast furnace consists of a compound disconnected blowing engine, with 72-inch blowing tubes, made by the Southward Foundry & Machine Co., Philadelphia, Pa. The engine is running condensing, with Worthington barometric condenser. The pumping equipment consists of three outside packed Epping-Carpenter circulating pumps, with a capacity of 36,000,000 gallons in twenty-four hours; and one Belliss & Morcom engine, direct connected to a Rees-Roturbo pump, which has a capacity of 4,000 gallons per minute. The power equipment is operated from six 300 h.p. Stirling water-tube boilers.

Open-Hearth—The open-hearth furnaces are fired by groups of four standard hand-fired Duff producers, except in one instance, where two mechanically-fired Chapman producers are used. The Basic Siemens-Martin process is used. The plant is equipped with two 75-ton ladle cranes, built by the Shaw Electric Crane Co., of Muskegon, Ohio. The ingots are stripped and handled with a combination electric yard and stripper crane, built by the Alliance Crane Co., of Alliance, Ohio. The furnaces are charged with a standard Wellman-Seaver electrically-driven charging machine, are of the latest open-hearth design, and are equipped with Blair water-cooled port ends and hoods. The plant has an approximate capacity of 14,000 tons per month.

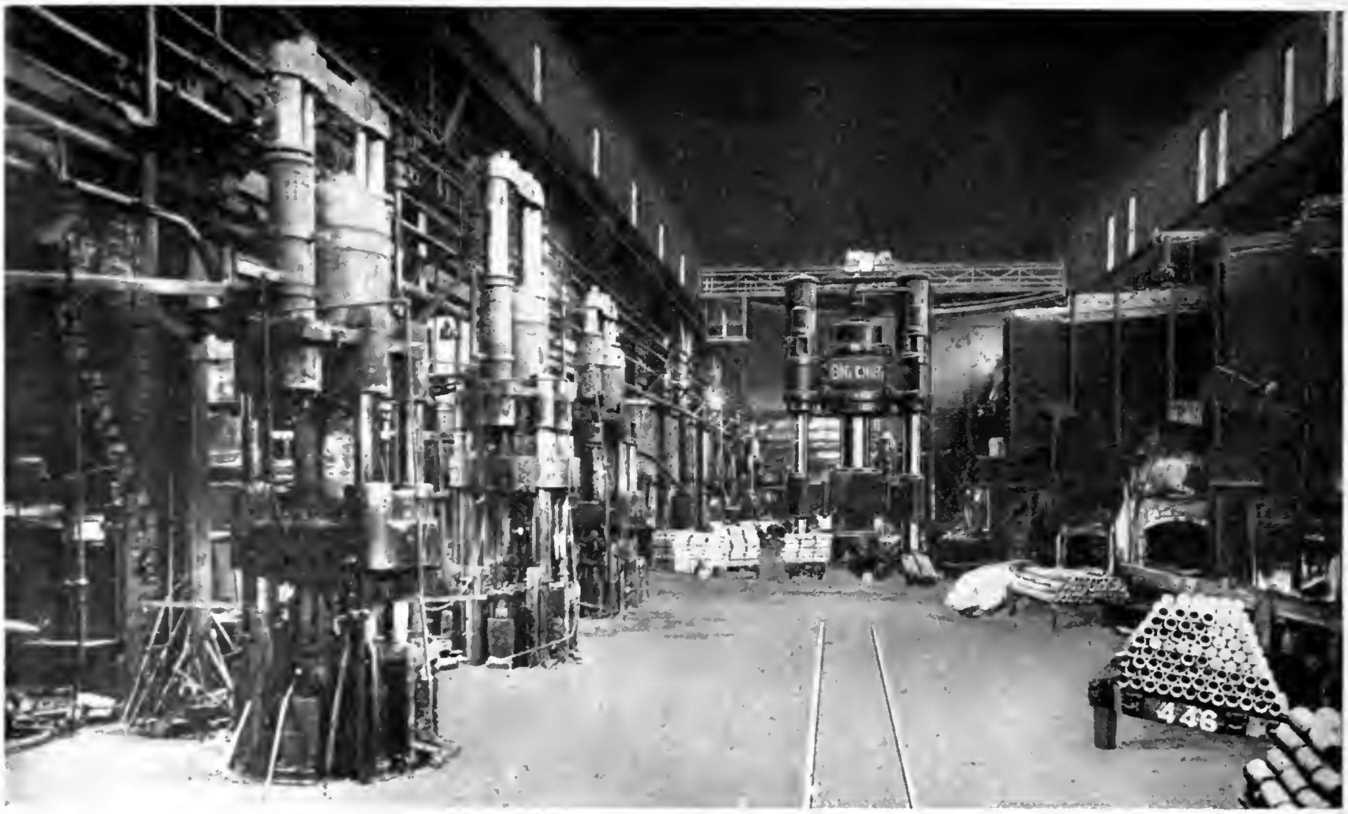
Welfare Work—Sydney Mines

At the various Sydney Mines plants, about 3,600 workmen are employed. The town of Sydney Mines is literally the creation of the "Scotia" Company, and is a model in every respect, comparing more than favorably with similar places either here or abroad.

When the property was acquired from the General Mining Association, the policy was adopted of dividing up the larger holdings into building lots in size of about 70 feet frontage and of 130 to 140 feet in depth. These lots were offered for sale to the general public at reasonable rates and to the workmen at a considerably lower figure. To further aid the workmen in their desire to become owners of comfortable homes, the Company agreed to build houses on the purchased lots on the instalment plan, each workman deciding on the plan of house most suitable for his requirements and repaying the advance at so much per month, with interest on the money. The whole amount being paid, the workman received a clear title to his house and land. The result has been the building of a clean modern town with attractive, comfortable, and substantial homes.

A large brick hospital costing in the vicinity of $65,000 has been erected, and is maintained by monthly subscriptions from every workman, by annual contribution from the company, the Town of Sydney Mines, County of Cape Breton, and Province of Nova Scotia. An efficient staff of physicians and nurses is always in attendance.

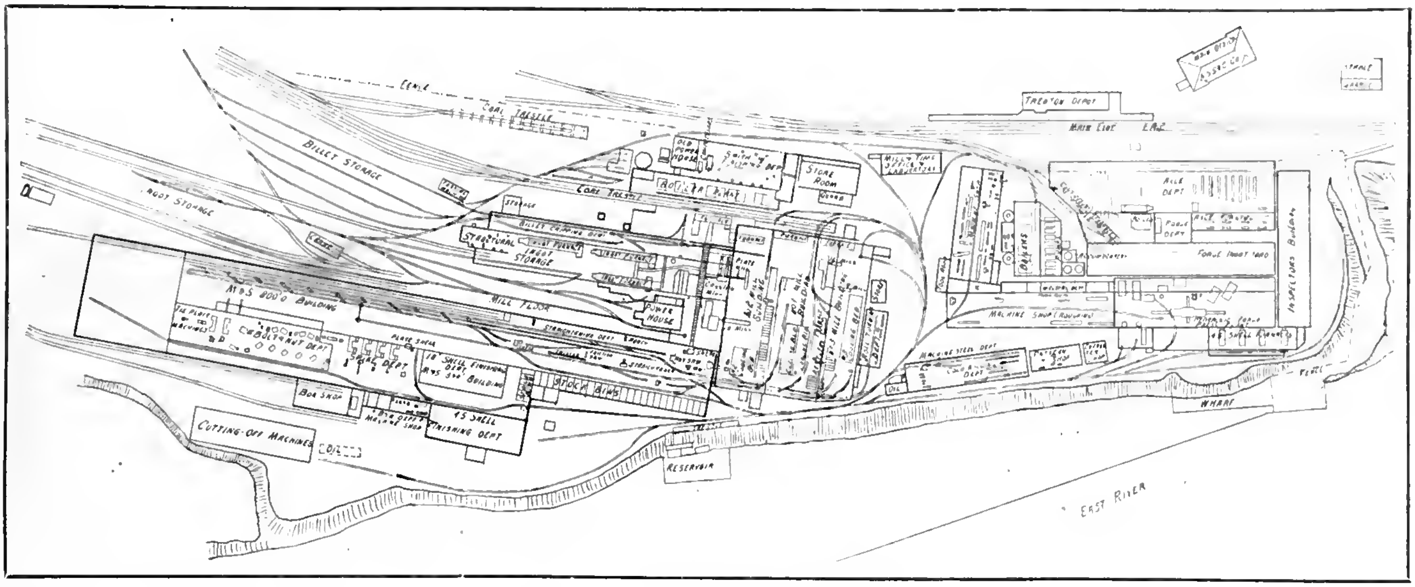
Well constructed ambulances constitute part of the equipment provided by the Scotia Company for the conveyance of the sick and injured. A "rescue car", furnished with all modern apparatus for fire fighting and rescue work in mines, and provided with all the necessities of a travelling hospital, stands on the railroad tracks in front of the general offices ready to be rushed to the point where needed. It is also worthy of mention that every officer of the Nova Scotia Steel & Coal Co., employed at the works, holds a certificate from the St. John's Ambulance Association, and is capable of rendering first aid to the injured.



FORGE PRESS SHOP, NEW GLASGOW, SHOWING "BIG CHIEF" IN CENTRE, WITH BATTERY OF SHELL FORGING PRESSES AND HEATING FURNACES AT LEFT AND RIGHT FOREGROUND, RESPECTIVELY.

First aid boxes are placed at the collieries and at the different surface plants, and two officers are employed, one on the surface and one underground, whose sole duties are to investigate conditions about the plant or mines, and take steps to insure protection for the men at their work. Further, by means of literature and notices, the "safety first" movement is encouraged and promoted among the employees with beneficial results. Change houses are also provided at all collieries where the workmen may wash and change their clothes on completion of their shift.

One other feature showing the friendly relations existing between Company and workmen is the provision made by the Company for the free transportation of the men every morning and evening from their homes to the different works. The trains are comfortable, well lighted and heated, are a great convenience to the employees, and their institution has been decidedly advantageous to the Company and the town of Sydney Mines generally. As a result, the building of houses is concentrated in the town and there are no struggling untidy villages surrounding the various collieries.



PLANT LAYOUT, NOVA SCOTIA STEEL & COAL CO., NEW GLASGOW, N.S.

New Glasgow Plant

At New Glasgow, or properly speaking, at Trenton, two miles from New Glasgow, are located the rolling mills, forges, machine shops, etc. of the Nova Scotia Steel & Coal Co. This plant is housed in a group of modern steel and concrete structures extending over 25 acres, and the various departments are equipped with the latest and, therefore, most up-to-date machinery for their special manufacturing purpose.

Rolling Mill Department

The rolling mill section consists of the following:—A 28-inch cogging mill of Lamberton design, complete with live rolls, and driven by a 33 in. x 38 in., double reversing, non-condensing, simple steam engine. On this mill, steel ingots, weighing $3\frac{1}{2}$ tons are reduced to billets of the different sizes required by the finishing mills.

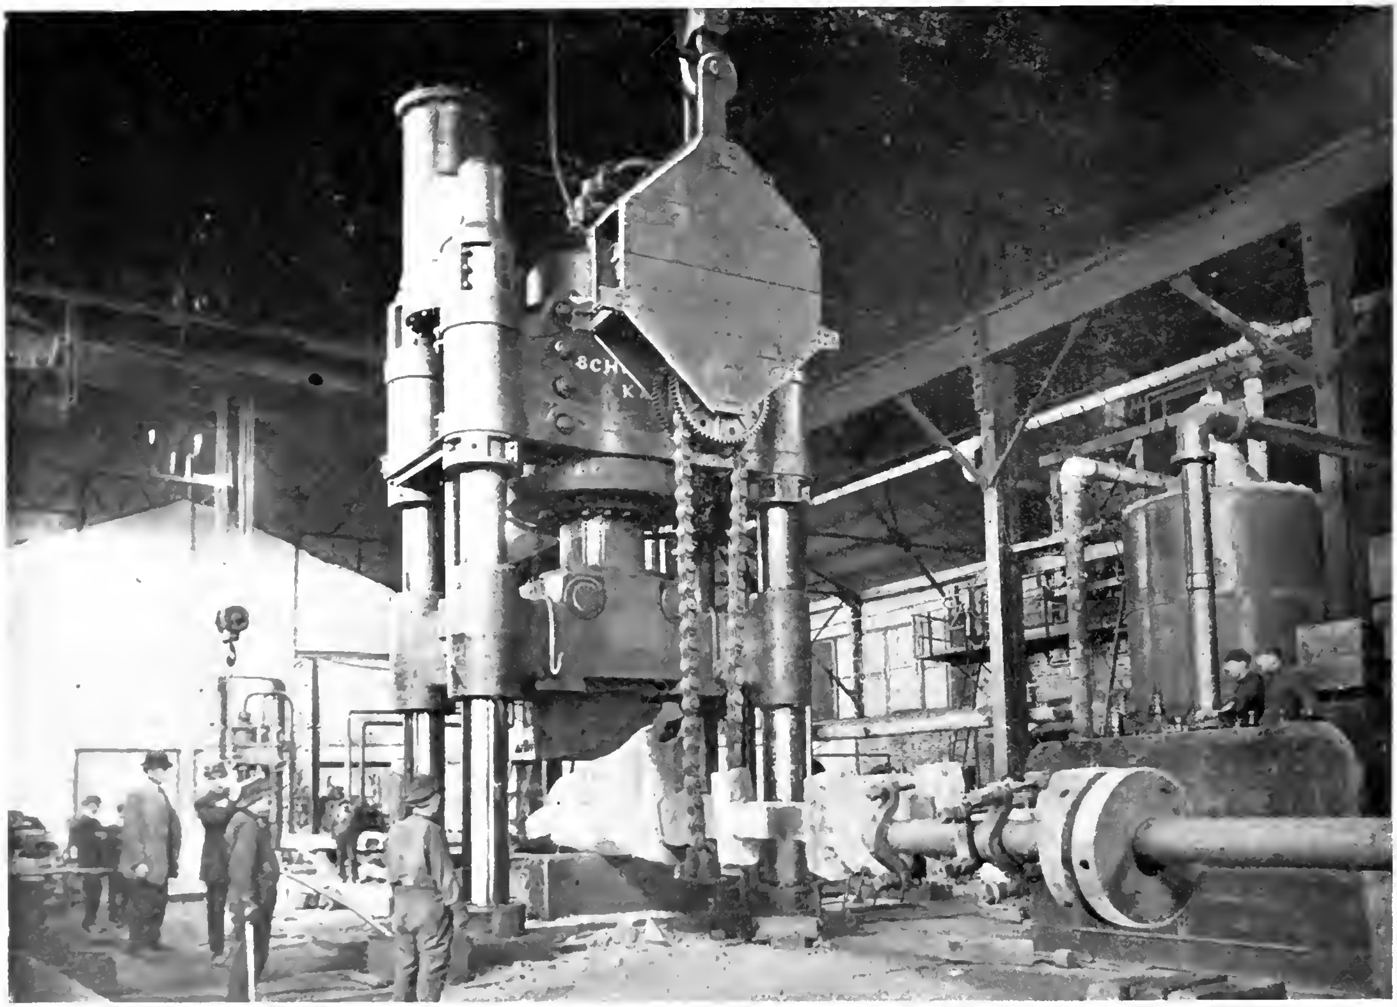
An 18 in. "Merchant" bar mill, with two set finishing housing, 3 high; one 9-in. guide mill, 3 high; one 9-in. guide mill with 14-in. roughing train, each of Belgian type, and complete with accessories, driving engines, cooling beds, shears,

PROPERTIES AND PLANTS OF THE NOVA SCOTIA STEEL & COAL CO., AND OF THE EASTERN CAR COMPANY AT NEW GLASGOW, N.S.

controlling electric cranes, continuous heating furnaces, etc.

A 20-in., 3 high plate mill, with capacity for rolling plates from No. 12 gauge up to one inch thick by 48 in. wide, and driven by a 30 in. x 48 in. double compound engine.

The high pressure hydraulic water used for the manipulating apparatus of the larger mills is supplied by an electrically-controlled multicellular centrifugal pump, driven by a direct-connected low-pressure steam turbine. Steam from the mill engines is delivered to a central



4,000 TON STEAM HYDRAULIC PRESS FORGING A SHIP'S RUDDER HEAD.

power station, where it is collected in a regenerator and passed on to Adamson-Rateau low-pressure turbo-generator sets. Two units of these, of 500 k.w. each, produce the electric current operating the various cranes and electrical machines throughout the plant.

The steel rolled in the above mills comes, as already stated, from the company's furnaces at Sydney Mines in the form of ingots. The latter, after reheating in modern continuous heating furnaces of the contra-flow type, are cogged down in the slabbing mill to the various size billets required, and then sent to the smaller mills to be rolled in a variety of product. In the rolling mill section, all of the standard merchant bars, flats, rounds, squares, angles, tees, tram rails—40 lbs. per yard and under, as well as numbers shapes for agricultural purposes, are taken care of. In connection with the bar mill, there are cold twisting bar machines, capable of twisting bars up to 2½ inches square for use in reinforced construction of buildings, bridges and other structural work. The 18-in. bar mill produces rounds up to 5 inches in diameter, squares up to 4 inches square and flats up to 15 inches wide. The 9-in. bar mill produces smaller sizes of rounds, squares and flats of all sections and shapes as required.

Spikes, Rivets, Bolts, etc.

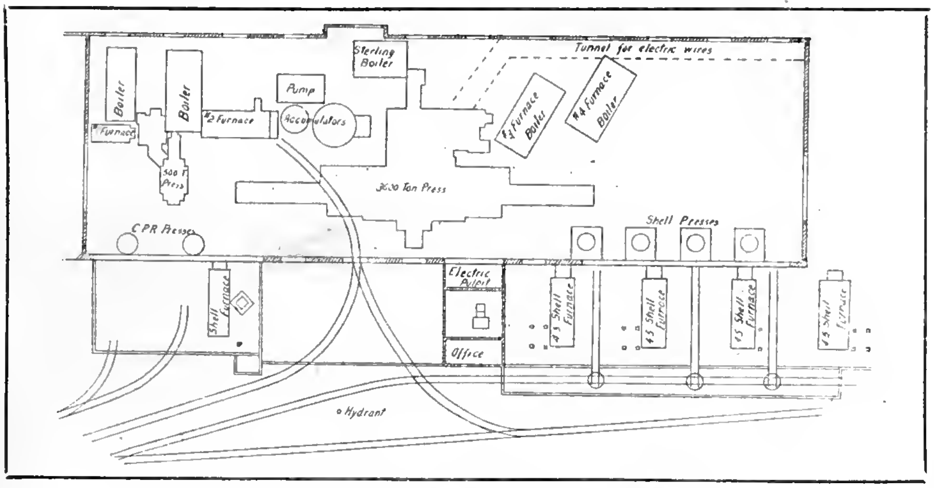
The railroad spike, rivet, bolt and nut, track tie and fish plate, reeled machinery steel and other finishing departments are located in two steel and concrete buildings, which cover 2½ acres of floor space, and are equipped with all the latest machinery. Some idea of the magnitude of the operations carried on here can be gathered from the fact that over 700 varieties of bars, plates, angles, etc., are annually turned out from these mills and their attendant finishing departments. Standard bolts, nuts and rivets of the more common sizes for general engineering services are a feature of this department, as is also the equipment for producing polished or cold rolled steel shafting.

Fluid Compressed Steel Forging

In every branch of industry, steel is required. Our civilization calls for it as a necessity. The demand is for sound steel, and it is recognized by the industrial world that failure to secure this all-important product is the cause of many of its greatest losses. Without subjecting the metal to some process as that already described, inability to produce a thoroughly reliable steel to meet the most exacting requirements must be at once and fully admitted.

The mere existence of this desired material—sound steel is, however, not enough: it must be manufactured into marketable products by the aid of tools, conforming in their action to the nature of the metal, as well as producing same in an economical manner. That is, while fluid compression is of vital importance to steel, the treatment of this raw material in the production of high-class forgings demands special care on the part of the mechanic, and the utilization of the best machinery. Bearing this in

mind, the further treatment of fluid-compressed steel for the production of high-class forgings was closely studied by the "Scotia" management, with the result that a complete forge plant does duty now in place of that which first made and maintained the company's



LAYOUT OF FORGE PRESS SHOP, NEW GLASGOW.

reputation for so long a period. The forging plant installed at the New Glasgow Works contains two of the most modern steam-hydraulic presses in use to-day. A brief description of this plant, with a statement concerning its products follows. This can perhaps best be introduced by a short summary of the history of heavy forging presses.

Concerning Heavy Forging Presses

Nasmyth's invention of the steam hammer in 1833 revolutionized the forging process of his day. During the latter part of the nineteenth century enormous progress was made in engineering and ship building, therefore, forgings were required of a size unknown not many years previous. In turn, this resulted in a great increase in the size of forging appliances. Steam hammers were largely used at first, and served their purpose well, but as the size of forgings grew, the hammer, being unable to develop a blow with sufficient penetration, became more and more unsatisfactory, and hydraulic forging presses, operated by means of accumulators, were introduced. Among the first of these was one constructed at the Armstrong Works in 1850. However, they proved so slow in operation and so expensive, that large steam hammers could still successfully compete with them. In 1860, a hammer was installed at the Krupp Works, Essen, Germany, having a 50-ton ram, and 1,000-ton anvil, while as late as 1901, a 125-ton steam hammer was installed at the South Bethlehem Works of the Bethlehem Steel Co. Although the latter was easily the largest hammer ever constructed, it was early replaced by a more efficient press.

With a hammer of this size, the force of the blow was enormous, but there were numerous difficulties in its operation. The energy developed, depending upon the weight of the falling parts, and the height through which it acted, was delivered suddenly and was exerted for but a moment. Repeated blows were, therefore, necessary, taking longer time than the press, and with a consequent low efficiency in steam consumption. The constant vibration made it difficult to keep a large hammer in adjustment, and wear and tear was excessive. Lastly, the lack of control with which the blow is delivered made it difficult to produce good work, and particularly to finish up heavy forgings. Thus, the relatively small output and high operating cost make hammers economically as well as technically unsuccessful in dealing with heavy forgings of every kind.

CAR WHEEL AXLE FORGING HAMMER IN OPERATION.

The need for a more effective and cheaper method of manufacture was met by the "Steam-Hydraulic" Press, introduced in the late eighties, in which are united the advantages of the steam hammer, combined with those of the hydraulic press. In this apparatus, steam cylinders lift the striking piece or tup, which thus moves with the speed and force of a steam hammer; while constant hydraulic pressure may be supplied at any stage of the stroke by a large water cylinder. This hydraulic pressure water is intensified in, and flows from, a separate apparatus called an intensifier. Thus, the pressure and speed of blows and compression can be varied widely to meet different conditions. Also, the energy required for producing high hydraulic pressure is called for only when needed. In the most modern type, in which the "Scotia" presses are the last word, these features enable much larger as well as a greater range of work to be performed.

Steam-Hydraulic Press Product

The product of a modern steam-hydraulic press is denser and more homogenous than can be secured with the steam hammer, due to the effect of the blow of the latter not penetrating to the centre, in contradistinction to the uniform kneeding effect of the press; while the amount of work that can be done by the latter at one time with little variation in temperature tends strongly to create a better product. The required heat treatment is simplified by reducing the number of heatings and their duration. It also reduces the liability of damage due to working at a blue heat. The greater uniformity and reliability of steam hydraulic forgings make their use imperative wherever exacting forging requirements have to be met.

The New Glasgow plant consists of two presses, each complete with manipulating devices, heating furnaces, etc.,

housed in a steel, brick and concrete building, 240 ft. by 72 ft. Two electric cranes of 50 and 30 tons capacity respectively, command the entire building. One press has a capacity of 600 tons, the other of 4,000 tons. The steam pressure is 140 lbs. per square inch. The larger press has a space of 128 ins. by 64 ins., between supporting columns, a short stroke of 7 in., a total stroke of 80 in., a weight of 740,000 lbs., and is adapted for forgings up to 75 tons. As the presses are exactly similar, except in size, the following description fits each:

ROD AND BAR MILL.

Forging Presses Description

Each installation consists of the press proper, the prefilling water tank, and the patent hydraulic intensifier. The press consists of a heavy base plate, embedded in the concrete foundations on which stands the anvil, also the four-forged steel columns which support the press head. Situated near the top of the press are two return steam cylinders, and the hydraulic or ram cylinder, which is located on the centre line. Immediately below the press head is situated the press traverse, the upper end of which is attached to the piston rods of the three cylinders above referred to. Below the traverse is fastened the upper forging tool or tup. The traverse has four bushed guides, encirling and sliding on the supporting columns to keep it in alignment and take up the heavy side strains when the ingot is not exactly under the tool centre.

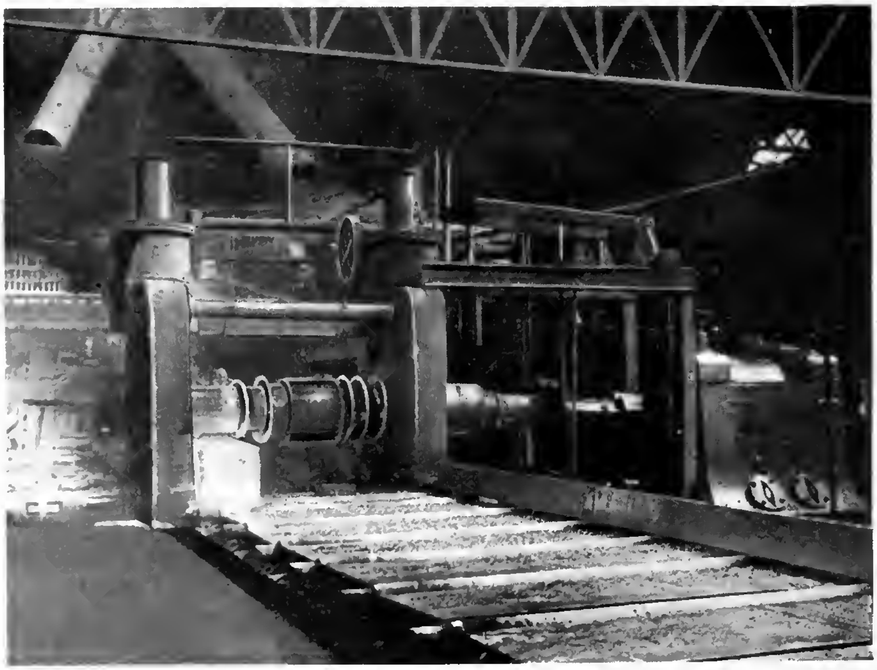
The prefilling water tank is an air chamber equipped with a pump for charging to a certain level at the pressure of 65 lbs. to the square inch. This tank supplies water to the ram and intensifier cylinders, and again stores the water which leaves the ram cylinder when the piston rises, the flow being automatically controlled by a water valve.

The intensifier, which produces the high hydraulic pressure, consists of two cylinders, a large one, with steam actuated piston, placed immediately above a smaller one containing water. They have a common piston rod, the lower end of which, extending through and working in the water cylinder, acts as the plunger of a force pump. When the steam cylinder piston moves upwards, the water is forced from an opening near the top of the lower or water cylinder, at very high pressure owing to the difference in their diameters, and enters the ram cylinder, giving a greatly increased pressure there. The intensification is fifty to one, and gives a water pressure of $3\frac{1}{2}$ tons per square inch in the ram cylinder.

This type of intensifier, we are informed, possesses many advantages over that of the ordinary type where the steam cylinder is below, in that the design of the whole is lower, giving freer access to the working parts. The piston rod is always in tension, resulting in less wear and tear on the glands, which, therefore, are more readily kept tight. Vibration in the press is largely eliminated by the valve arrangement which admits steam on the inside of the lower cover of the steam cylinder, thus providing a steam cushion, and resulting in a noiseless drop. The valve system is automatic in controlling the press, and prevents any injury to the tups or dies due to momentum, for instance when cutting, for the weight of the tup is at once taken up by the under steam in the press traverse steam lifting cylinders. All the valves controlling the various operations are located at the side of the intensifier, and all are operated by a single lever, so connected in a system that the press follows the control lever movements in speed and stroke.

Forging Presses Operation

The press may be operated in four different ways, and under each the tup may at any moment be arrested instantly, and a new stroke inaugurated by a single movement of the controlling lever. The tup may be actuated (1)—by the steam cylinder alone, the press then operating like an ordinary single-acting steam hammer; (2)—with intensifier giving high pressure only toward the end of the stroke (this is the method used in ordinary forge work); (3)—with high pressure throughout the entire stroke, used in pure press work, cutting, etc.; (4)—with intensifier and under steam cylinders, which results in rapidly repeated heavy blows delivered at a fixed height. This method is used for finishing work to exact size, the length of the stroke being automatically controlled. At all times, steam pressure is acting on the under side of the press steam pis-



28-INCH "LAMBERTON" INGOT COGGING MILL.

ton. This serves as a cushion or restraining force to any sudden movement of the tup, which would be caused by its shearing through the metal under it, thus resulting in an instantaneous diminution of opposition to the forward movement of the shearing tool. A maximum stroke of only seven inches is possible with high hydraulic pressure, owing to the small capacity of the intensifier hydraulic ram cylinder, but by means of a single stroke of the control lever, the ram cylinder may be refilled with water, and the press piston given another downward stroke of seven inches. This operation of taking a new hold as it were, may be repeated throughout the total stroke of the tup, enabling pressing and cutting to continue at a uniform pressure.

BATTERY OF SPIKE-MAKING MACHINES.

Mechanical Handling Equipment

When making heavy forgings, whether with hammers or presses, the piece must be frequently moved and turned, especially when the finishing strokes are being given. To do this speedily and cheaply, a mechanical handling equipment has been installed, the forging being suspended and rotated by an endless chain driven by electric gear attached to the forge crane. This crane may be operated from the usual cage suspended from the crane, and also from a pulpit at floor level, close to the presses. Hydraulic manipulator and mandrel gear are provided for forging long, massive shafts, cylinders and turbine casings, etc. There are also two hydraulic operated rests on each side of the big press for supporting long forgings. These have a travel of 20 feet each way. Hydraulic manipulating gears are provided for adjusting the different bottom anvils. On the large press, the stroke of this appliance is about 12 feet. Rapid working, range of utility, economy and every other requirement of modern forging practice, are well secured by this plant. The steam consumption is extraordinarily low, as the cylinders do not have to be kept filled continuously. The plant as a whole is exceedingly compact.

Cold Rolling Department

In the cold rolling department, the equipment consists of five machines for cutting shafting, but at present on shell stocks; three of these probably built at the plant, one of the others being made by Marshall, Husehart Mfg. Co., Chicago, Ill., and the other by the Brighton Mfg. Co., Shelby, Ohio.

One shear and straightener machine, by Long & Allstatter Co., Hamilton, Ohio.

One straightener machine for cold roll shafting.

One small reeler; one drawing machine for shafting, by Goldie & McCulloch Co., Galt, Ont.

One big reeler, by Goldie & McCulloch Co., Galt, Ont.

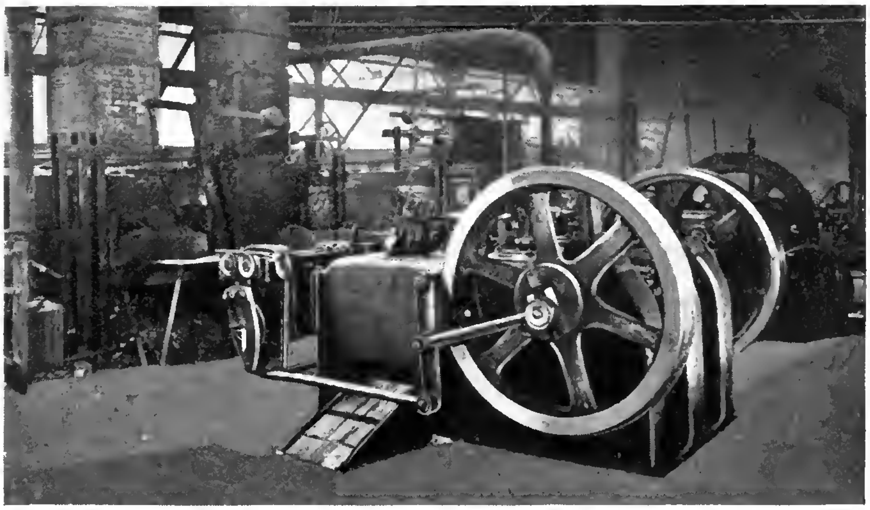
One small and one large turning machine made at the plant and by the Brightman Mfg. Co., Cleveland, Ohio, respectively.

The following machines in addition to the above are in continuous employment cutting shell stock:—

Two lathes on 4.5-in. stock, by John H. Hall & Sons, Brantford, Ont.

Five machines for cutting 60 pdr. shell stock, by Hurlbutt Rogers Machinery Co., South Sudbury, Mass.

Three machines for 60 pdr. shell stock, by Davis Machine Tool Co., Rochester, N.Y.



BATTERY OF BOLT AND NUT MACHINES.

Smith and Finishing Departments

For the work of this department, there are installed one 800 and one 500 pound steam hammer, both built by Bells Steam Engine Works, Buffalo, N.Y.; three sets plate shears, embracing one alligator plate shears, one finishing plate shears, one plate shears for miscellaneous work, also thirteen blacksmith forges.

Ingot Storage and Heating Furnaces

The ingot storage floor is supplied with narrow gauge railway for transporting ingots. A 15-ton traveling crane is installed for the transfer of ingots to A.E. and A. W. furnaces. After passing through the latter the ingots are carried to the 28-inch cogging mill for rolling into the various sizes required. Each ingot weight about 3½ tons and remains about 10 hrs. in the heating furnace. Traveling the entire length of furnace, they continally arrive at a higher temperature until the desired amount of 1,700 deg.-1,900 deg. is reached; the variation in the two temperatures quoted being dependent on the percentage of carbon present in the ingot.

The furnaces hold from 38 to 40 ingots each, and are 82 ft. by 10 ft. The ingots travel through the furnace on water-cooled skids 3 ft. apart, and 2 ft. off bottom of furnace, permitting fire to travel over and under ingots. One man through the medium of hydraulic pressure attends to all the operations of canting and delivering ingots to electric motor trucks for transfer to cogging mill. The furnaces were designed and constructed wholly by the "Scotia" Co., the manipulators for canting the ingots being covered by patents held by the company.

The ingots are pushed in at back end of furnace and out at front by a hydrau-

lic pusher, thence out to transfer car which is attached to an endless steel cable, being finally deposited at the live rolls driven by electric motor. After ingots are rolled down to required sizes—3¼ in. by 3¼ in., or 8 in. by 8 in., they are carried along the live rolls to the hot billet shears where they are cut into required length, cooled and delivered to the different mills for further rolling down to the various shapes ordered, such as angles, rods, shafting, etc.

In addition to the above ingot furnaces there are five others similarly constructed to heat smaller billets for mills Nos. 1, 2, and 3. No. 2 mill engine operates rolls for rails, fish-plates, angles, 15 and 18 pdr. shell stock, 4.5-in. shell stock, 90 pdr. shell stock, flats, rounds, etc. At the far end of these rolls are two fish-plate machines; these are also used for 18 and 15 pdr. shell stock, or heavy plate. Both are driven by electric motors. Other equipment consists of one steam drop hammer for straightening fish-plates; shears for angles, flats, etc.

Mill Buildings, 1 and 3

In No. 3 mill building, the equipment consists of a mill engine by Matheson & Co., New Glasgow, for No. 3 mill; also shears for cutting flats, spike material, scrap, etc.

No. 1 mill building, contains a mill engine which drives rolls for producing small flats, rounds, discs, small rails, etc.; other equipment consists of two steam shears for cutting up scrap; one oil heated annealing furnace for hardening shell stock, rounds, etc.; two reelers for reeling machinery steel rounds, etc.

Billet shipping depot—This consists of a long storage floor supplied by two narrow gauge tracks with storage capacity between for material in transit.

Manufacturing and Shipping Departments

The manufacturing and shipping departments consist of two buildings—one 800 ft. by 75 ft., and the other of 540 ft. by 75 ft., with a new extension of 150 ft. by 140 ft. The first is equipped with a standard narrow gauge railway and the following variety of machines:—

One store room shears for cutting small stock for shipment and made by the U.S. Engine Foundry Co., Youngston, Ohio.

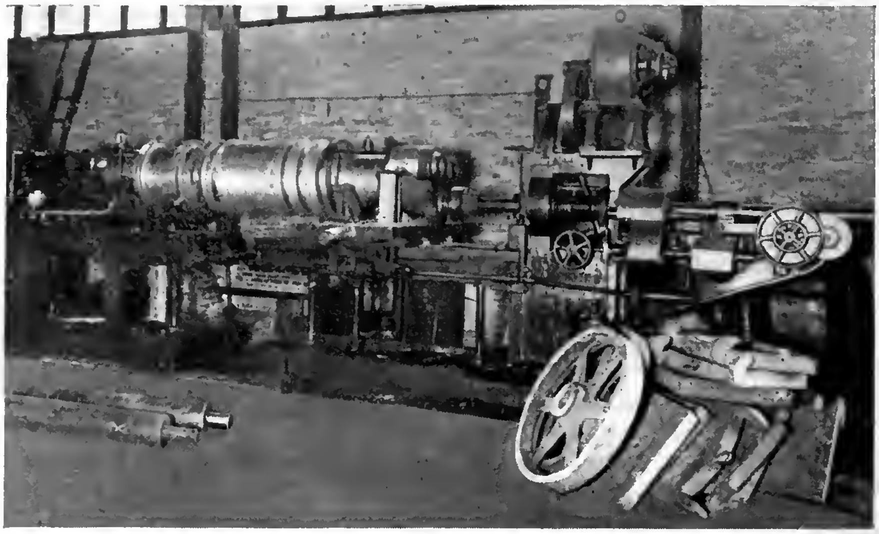
One straightening machine for angles, shell stock, rails, etc., made by Kane & Roache, Syracuse, N.Y.

Two small straighteners for small flats, wagon tires, small angles, etc., made by Kane & Roache, Syracuse, N.Y.

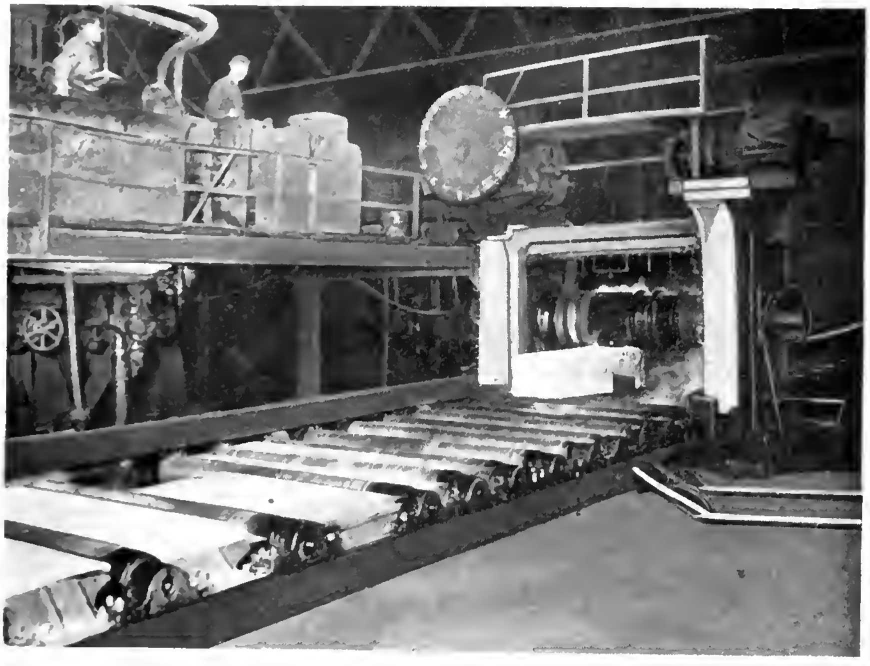
One hot saw for cutting ends off angles, bars, etc.

One vertical shears for shearing heavy billet stock, made by the Lewis Foundry Machine Co., Pittsburg, Pa.

One twister for twisting bars for reinforcing concrete, etc., made by Ransome Bros., and driven by a 60 h.p. continuous current motor of 220 volts, type.



WOBBLING A 28-INCH COGGING MILL ROLL ON HORIZONTAL BORING MILL IN MACHINE SHOP.



COGGING MILL SHOWING 3½ TON INGOT UNDER OPERATION.

One heavy angle shears made by Jones, Burton & Co., Liverpool, England.

One rail puncher by Jones & Burton.

One hot saw for cutting heavy shell stock, made by the Mesta Machinery Co., Pittsburg, Pa.

One hot billet shears for cutting rolls from 28 in. mill.

One Stirling saw for heavy shell stock, made by the George Gorton Machine Co., Racine, Wis.

One plate shears for shearing heavy plate made by E. W. Bliss Co., Brooklyn, N.Y., and driven by continuous current motor, supplied by the Canadian General Electric Co.

One "Little Bin" cutting-off machine for shearing 15 and 18 pdr. shell stock, and for shearing billets for No. 1 and 2 mills, made by U.S. Engineering & Foundry Co., Youngstown, Ohio, and driven by direct current motor of 50 h.p.

Bolts, Nuts, and Spikes

The spike department takes care of a daily output of 100 tons of finished spikes, each machine installed being capable of producing railroad, mine and other spikes of varied size and shape.

The bolt and nut department equipment is modern and up-to-date, and capable of producing 50 tons of finished material daily. All sizes of railway and structural bolts and nuts are made, enormous quantities being supplied to the

Canadian railways and the larger contracting firms throughout Canada.

The rivet department is equipped for a daily production of 50 tons of rivets of all sizes and styles required for structural work, tank, car, and boiler work, rivets for the latter conforming to Lloyd's and British Board of Trade specifications and requirements.

Lower Floor

The 540 ft. M. and S. building contains the 18 pdr. shell finishing department, and the bolt and nut department which is equipped as follows. All drives are by electric motors:—

Two tie plate punching machines, by Hilles & Jones, Wilmington, Del.

One thread and bolt machine, by Waterbury Farrel Foundry & Machine Co., Waterbury Conn.

Three thread and bolt machines by National Machinery Co., Tiffin, Ohio.

Five thread and nut machines, by the Acme Machinery Co., Cleveland, Ohio.

Five boring machines, by the National Machinery Co., Tiffin, Ohio.

One nut boring machine, by the Acme Machinery Co., Cleveland, Ohio.

One drill, by W. F. & John Barnes Co.

One tumbler for cleaning nuts, bolts and discs.

Three nut lathes, by the Acme Machinery Co., Cleveland, Ohio.

Five bolt-threading machines, by the Acme Machinery Co., Cleveland, Ohio.

One machine for rolling bolts, by the Waterbury Farrell Foundry & Machine Co., Waterbury, Conn.

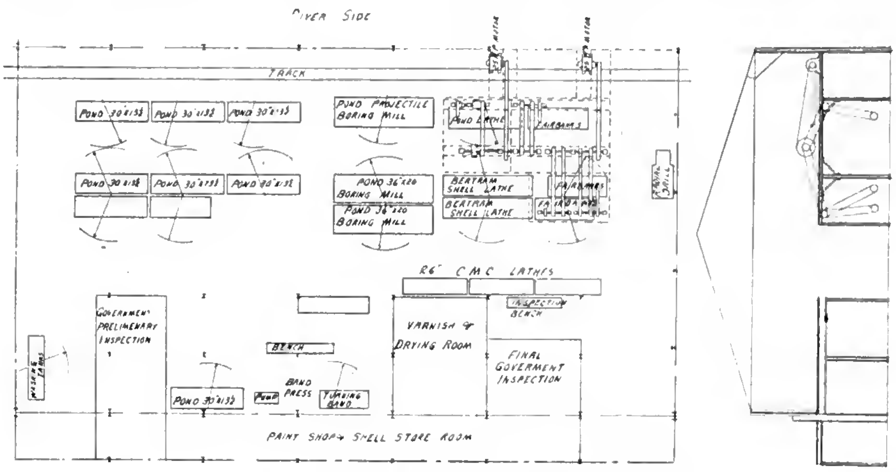
One bar shears for nuts and bolts, by the Badger State Machine Co., Janesville, Wis.

stock, with oil furnace in connection, by the Acme Machine Co.

Five bolt and rivet machines, by the Acme Machinery Co.

In the bolt and nut department, the following furnaces are installed:—

Two continuous rivet heating furnaces, each being 9 ft. by 24 ft.



MACHINE TOOL LAYOUT, 9.2-INCH SHELL SHOP.

Ten bolt and nut machines, by the Acme Machinery Co.

There is being installed one disc machine for 9 2 shells, by the Acme Machinery Co.

Departmental Machine Shop

The machine shop for this department contains one milling machine (No. 2.A.) by Brown & Sharpe, Providence, R.I.

One boring machine, by the John Bertram & Sons Co., Dundas, Ont.

One Champion drill, No. 20, by the Champion Blower & Forge Co., Lancaster, Pa.

Two 20 in. B.G. lathes, by J. J. McCabe. One Newton lathe.

Thirteen bolt and nut furnaces, 6 ft. by 10 ft.

Two pit spike furnaces, 5 ft. by 8 ft.

Spike Department

The spike department contains four continuous spike furnaces, 9 ft. by 24 ft., also the following machines:—

Two pit spike machines, by the National Machinery Co., Tiffin, Ohio.

Four railroad spike machines.

One tumbler for cleaning spikes and discs now working on shell stock.

Three disc boring machines, by the John Bertram & Sons, Dundas, On.

Two threading machines, by the Acme Machinery Co., Cleveland, Ohio.

Two burring machines, by the Acme Machinery Co., Cleveland, Ohio.

Roll Turning Department

The roll turning department contains one lathe for turning cogging rolls up to 28 in. diameter; three lathes, one of which was made by Miller & Co., Coatbridge, Scotland, the others being made at the plant. This shop is supplied with a 7½-ton Cleveland crane.

Box Department

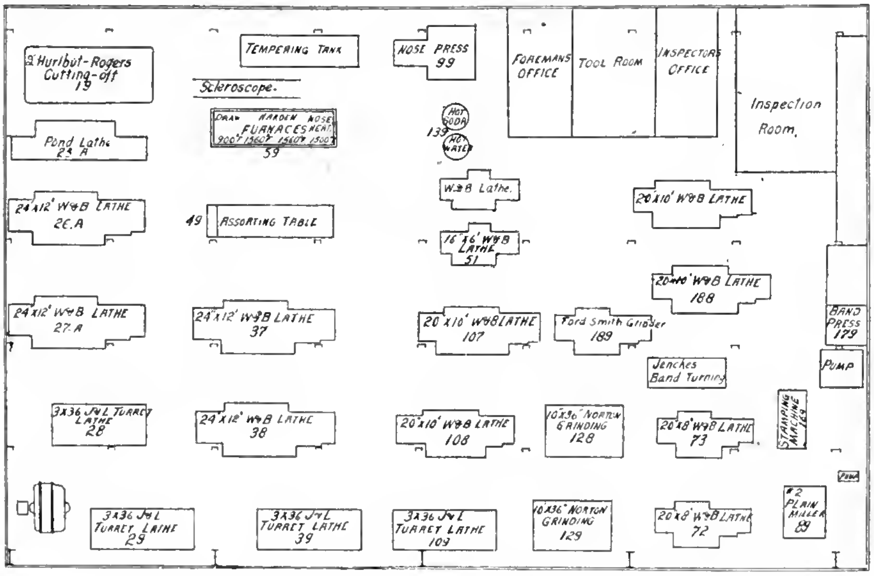
In the box department are manufactured the boxes in which bolts, nuts, and spikes, etc., are shipped. The shop is equipped as follows:—

One engine and boiler, by the Robb Engineering Co., Amherst. N.S., driving the following machines:—

One box nailer, by the Morgan Nailing Co., Rochester, N.Y.

One circular saw; two stainers.

One standard gauge, depressed railroad track for bringing in lumber, etc.



MACHINE TOOL LAYOUT IN 18-PDR. SHELL FINISHING SHOP.

Upper Floor

The upper floor contains:—One 4 in. header for 4.5 shells, by the Ajax Machine Co., Cleveland, Ohio.

One 3-in. header, for 18 pdr. shell

One surface grinder, by the Springfield Mfg. Co., Bridgeport, Conn.

Two general purpose lathes, by Schumacher & Boye, Cincinnati, Ohio.

One oil furnace, steel saws, etc.

Pattern Shop

The equipment in the pattern shop

consists of one 34-in. band saw, by John Bertram & Sons Co., Dundas, Ont.

One planer, by J. Fay & Egan Co., Cincinnati, Ohio.

One buz planer, by Goldie & McCulloch Co., Galt, Ont.

FINISHING A 25-FT. STEEL SHAFT IN MACHINE SHOP.

One swinging cut-off saw, by J. A. Fay Co., Cincinnati, Ohio.

One rip saw by the Egan Co., Cincinnati, Ohio.

One lathe, by J. A. Fay Co., Cincinnati, Ohio.

One knife grinder, by Chas. A. Strelinger, Detroit, Mich.

One stamping machine, by Williams & Wilson, Montreal, Que.

Heavy Forging Department

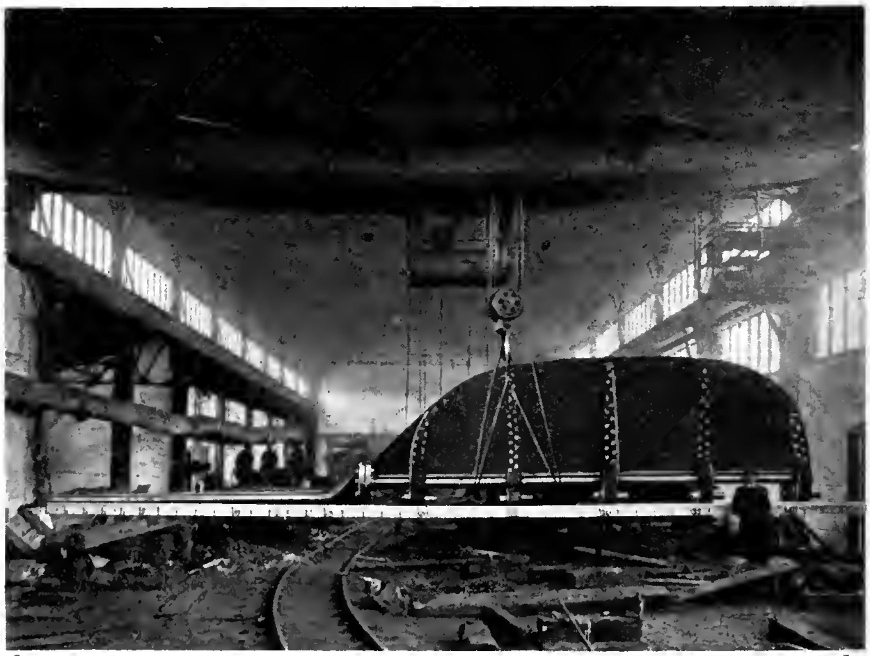
The equipment here consists of one 4,000 ton steam hydraulic press, and one 600-ton steam-hydraulic press. These are used for forging heavy pieces, such as rudders, crank shafts, etc., up to any weight. Two furnaces capable of heating 30 ton ingots are in close proximity to the 4,000 ton press. Return tubular boilers are installed over each furnace to utilize all the waste heat from the latter. Two smaller furnaces are used for the 600 ton forging presses, one furnace having one boiler over it.

Shell Forging Department

In the forge building there are installed six hydraulic shell presses built by C.P.R. for forging exclusively 18 pdr., 4.5 in., and 60 pdr. shells. The power of these presses is 268 tons. They are supplied with 1,500 lbs. per sq. inch water pressure by two accumulators 18-in. by 18 ft., manufactured by the R. D. Wood & Co., Philadelphia, and work in conjunction with six 19-30-5-24 Worthington pumps. The presses work in three 8-hour shifts. Six heating furnaces 8 ft. by 20 ft., equipped with American automatic stokers are used for heating the shell blocks for the above presses.

The boiler installation in the forge department consists of three 500 h.p. Stirling and two-400 h.p. Babcock & Wilcox water-tube boilers. These supply steam to six Worthington and three Wilson-Snider pumps. The capacity of the former is 170 water horse-power and of the latter, 290 water horse-power. The boiler gases pass into two steel self-supporting stacks.

Three accumulators supply hydraulic pressure to one 1,500-ton (with intensifier) and one 500-ton hydraulic presses, also to one draw-bench 18 in. by 12 ft., and to one draw-bench 18 in. by 18 ft. for forging 8 in. and 9.2 in. shells. They C. P. R. presses in shell forging department already mentioned.



RUDDER FOR SS. "GRYFERVALE." WEIGHT COMPLETE 22,000 POUNDS.

Two continuous furnaces, 5 ft. by 50 ft., heat 8 in. and 9.2 in. shell blocks for the 1,500 ton and 500 ton presses. The shell blocks are pushed in at the back of also supply hydraulic power to the six furnace by a hydraulic pusher and are taken out at front by continuation of the process. The shell blocks are next put through two operations on the presses upsetting and piercing, being afterwards transferred to the draw-bench, where they are drawn down to finished-forge size. The draw-benches were supplied by the Mesta Machine Co.

Axle Turning Department

The railway car axle shop is one of the most up-to-date in the whole plant, containing, it is claimed, the best railway car axle manufacturing equipment extant. This department produces, we understand, a greater daily and monthly output than any other works in the British Empire; besides there are believed to be no shops on the European Continent with an equal output.

The axles are, of course, products of the "fluid compressed" steel plant at Sydney Mines, thus the high standard of excellence for both freight and passenger cars. Axles, forged, rough or finish turned, are being manufactured at the rate of over 5,000 per month.

The axle turning department contains the following machines which are used meantime for turning shell stock of various sizes.

One Bridgeford axle lathe, now turning 4.5 in. and 5 in. shell stock.

Two 5 inch lathes, by Williams Tool Co., Erie Penn., engaged on 4.5 in. and 5 in. shell stock.

One 5 inch lathe on shell stock.

One 24-inch lathe, by Wm. Sellers & Co., Philadelphia.

One 24 inch lathe, by Lodge & Shipley Machine Tool Co.

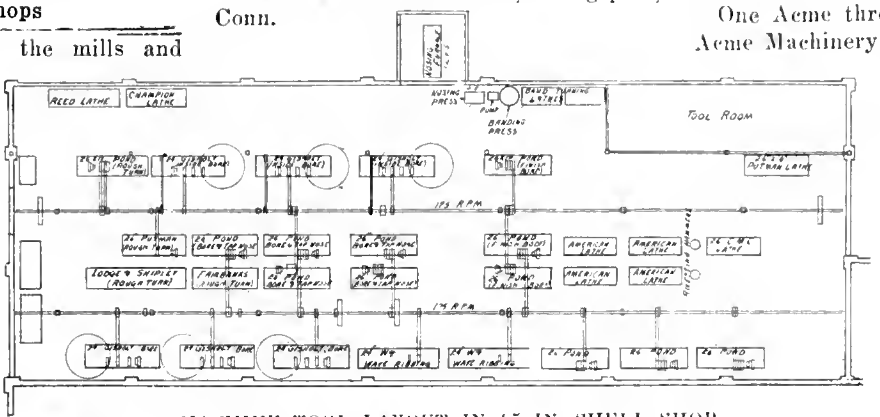
Three axle lathes, makers name not available.

One lathe, by Canadian Fairbanks-Morse Co., Montreal.

One Bridgeport lathe, and two other lathes whose makers' names are not available, also two cutting machines.

Machine Shops

In conjunction with the mills and heavy and light forge shops there are two large machine shops; one housed in the extension to the new forge building, equipped especially for turning up rough forgings and finishing the heavier classes of work, while the other is used on the lighter work. The list of machine tool equipment installed is as follows:—



MACHINE TOOL LAYOUT IN 4.5 IN. SHELL SHOP.

New Shop

One horizontal boring machine, by John Bertram & Sons Co., Dundas, Ont.

One drill, by John Bertram & Sons Co.

One boring machine for gear wheels, etc., by Herman L. Winterer, Philadelphia, Pa.

One Espen-Lucas, No. 2 saw for cutting shell stock.

One lathe, by the Fifield Tool Co., Lowell, Mass.

One lathe, by the A. R. Williams Machinery Co., St. John, N.B.

Two 45-inch lathes, for heavy rolls, shafting, etc., by Hulse & Co., Manchester, England.

One planer, by Loudon Bros., Johnstone, Scotland.

One Espen-Lucas saw for cutting heavy shafting, etc.

Two lathes by Niles-Bement-Pond Co., Pond Works, Plainfield, N.J.

Two lathes, type 3, No. 6, by the American Tool Works Co., Cincinnati, Ohio.

One Espen-Lucas saws for heavy shell stock.

The following makes of cutting-off machines are installed for operating on shell stock:

One Manning, Maxwell & Moore, New York.

Five Hurlbutt, Rogers Machine Co., South Sudbury, Mass.

One Gorton saw, size No. 2 B, by the George Gorton Machine Co., Racine, Wis.

One 50-inch diam. boring mill. John Bertram & Sons Co., Dundas, Ont.

One 10 ft. boring mill, by Smith & Coventry, Manchester, England, for large gears and rudder irons, etc.

Old Shop

The old machine shop contains the following:—One 36-inch boring mill, by the Baush Machine Tool Co., Springfield, Mass.

One 36-in. boring machine.

One boring mill, 50-in. diameter by the Bullard Machine Tool Co., Bridgeport, Conn.

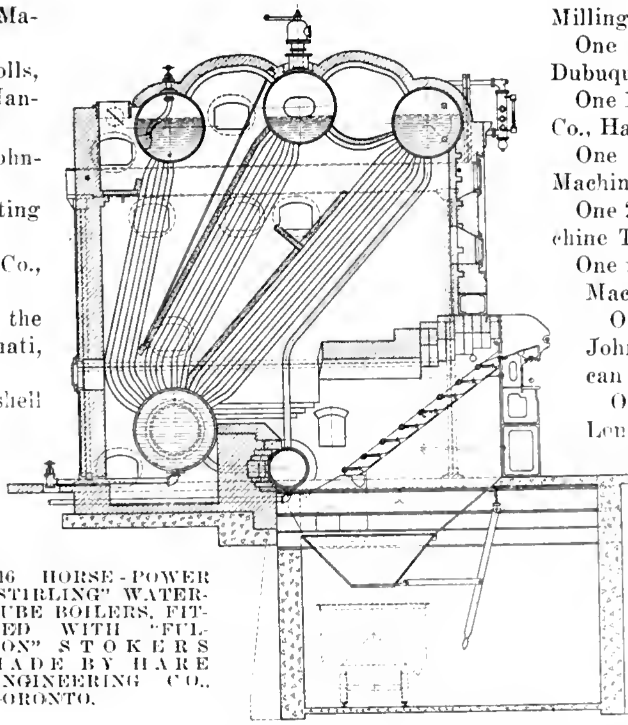
One finishing lathe, 20 ft. bed, by the John Bertram & Sons Co., Dundas, Ont.

One 24-inch lathe, 15 ft. bed, by the John Bertram & Sons Co., Dundas, Ont.

One planer for work up to 15 ft. by 5 ft., for planing bearings for hot saw, etc., by the John Bertram & Sons Co., Dundas, Ont.

One 16 inch lathe, by J. J. McCabe, New York.

One 22-inch Bradford lathe, by the Bradford Machine Tool Co., Cincinnati, Ohio.



316 HORSE-POWER "STIRLING" WATER-TUBE BOILERS, FITTED WITH "FULTON" STOKERS MADE BY HARE ENGINEERING CO., TORONTO.

One 20-inch Bradford lathe, The Bradford Machine Tool Co., Cincinnatti, Ohio.

One 19-inch lathe, by Flather & Co., Inc., Nashua, N. H.

One 56-inch Bertram lathe, 15 ft. bed, John Bertram & Sons Co., Dundas, Ont.

One 5 ft. (dia.) roughing lathe, by the New Haven Mfg. Co., New Haven, Conn.

One 4 ft. roughing lathe, by Bement, Miles & Co., Philadelphia, Pa.

One 20-inch lathe, by the London Machine Tool Co., Hamilton, Ont.

One Acme threading machine, by the Acme Machinery Co., Cleveland, Ohio.

One drill, by the John Bertram & Sons Co., Dundas, Ont.

One boring machine, by F. E. Reed, Worcester, Mass.

One saw grinder, by the Gigley Machine Co., New York.

One cutting-off machine, by the Higley Mfg. Co., New York.

One high duty shaper, by Gould & Eberhardt, Newark, N.J.

One radial drill, 8 ft. arm, by the John Bertram & Sons Co., Dundas, Ont

One drill press, by the Cincinnati-Bickford Tool Co., Cincinnati, Ohio.

One 16-inch lathe, by New Haven Mfg. Co., New Haven.

One key seater, by Baker Brothers, Toledo, Ohio.

One gear cutter, 60 in. dia. by 18 in. face, by the Cincinnati Gear Cutting Machine Co., Cincinnati. Ohio.

One milling machine, by the Cincinnati Milling Machine Co., Cincinnati, Ohio.

One gear cutter, by the Adams Co., Dubuque, Iowa.

One 14 inch lathe, by Pratt & Whitney Co., Hartford, Conn.

One 15 inch shaper, by the Hendey Machine Co., Torrington, Conn.

One 25 inch shaper, by the London Machine Tool Co., Hamilton, Ont.

One radial drill, 6 ft. arm, by the Pond Machine Tool Co., Plainfield, N.J.

One slotter, by T. Shanks & Co., Johnstone, Scotland, and one American shaper.

One grinder and planer, by the London Machine Tool Co., Hamilton, Ont.

One drill, by the John Bertram & Sons Co., Dundas, Ont.

One 22-inch lathe, by the John Bertram & Sons Co., Dundas, Ont.

One 18-inch lathe, by F. E. Reed, Worcester, Mass.

One 8-inch lathe, by the John Bertram & Sons Co., Dundas, Ont

One small lathe, by the John Bertram & Sons Co., Dundas, Ont.

One 18-inch lathe, by the Hill, Clarke Co., Boston, Mass.

One 18-inch lathe, by Chandler &

Farquhar Co., Boston, Mass.

One Niles-Bement-Pond lathe, 36 in. by 28 ft. bed.

One boring mill, by the Canada Machinery Corporation, Galt, Ontario.

The tool room equipment of the old and new machine shops consists of a shaper, by Gould & Eberhardt, Newark, N.J.; a milling machine, by the Rockford Milling Machine Co., Rockford, Ill.; a universal grinder, by the Walker Grinder Co., Worcester, Mass., and a 14-in. Lodge & Shipley lathe.

Ordnance Department

Shortly after the opening of the European war, a demand arose for shells of various types and sizes. To meet this demand the "Scotia" Company started at once the manufacture of suitable steel, made the blanks and rough-forged shell cases, the latter being shipped to different shell machining plants, both in Canada and Great Britain. The first shell made in Canada complete originated at the "Scotia" plants. With succeeding months, more and more orders for shells were placed in Canada, and not only were the quantities increased, but the sizes and types materially so.

In common with our metal-working plants generally, "Scotia" found it necessary to extend and add to its plant and equipment. As a result we find additional forge and machine shops erected and equipped with the latest tools and appliances for producing shrapnel and high explosive shells all the way from 15 and 18-pdrs. of the former, and from 4.5 in. to 12 in. of the latter. The accompanying tabulated statement of a twelve months' output of shells gives a fairly good idea of the facilities which the "Scotia" plant offers for the work.

At the present time production is getting under way relative to 6-in., 8-in. and 9.2-in. shells, right from the ore to the finished article.

18-Pdr. Shrapnel Shop

The machine tool equipment in this shop is driven for the most part by a 75 h.p. C.G.E. motor. In addition, a Ford-Smith grinder is driven by 25 h.p. Canadian Westinghouse motor, while motors of the latter make, 2½ h.p., 5 h.p., and 5 h.p., drive a cutting compound circulating pump, a grinder and shell burnisher, and the nosing press respectively. The various items of machine tool and other equipment installed are as follows:—Lathe, by Whitcomb & Blaisdell Machine Tool Co., Worcester, Mass.; heating furnace, by Tate-Jones Co., Pittsburgh; nosing press, by John Bertram & Sons Co., Dundas, Ont.; banding press and pump, by Richard Dudgeon Co., New York City; Bertram marking machine; plain milling machine, by Becker-Brainard Milling Machine Co., Hyde Park, Mass.; pump for circulating compound to cutting-off machines, by Smarter-Turner Co., Hamilton, Ont.; three Chapman Double Ball Bearing Co. trucks; Jenckes copper band turning machine; Hurlbut Rogers cutting-off machines; Pond lathes; Shore Scleroscope, etc. Tool room equipment consists of emery stone, vise, and hand tools only.

HEAD OFFICE, NOVA SCOTIA STEEL & COAL CO., NEW GLASGOW, N.S.

4.5-in. Shell Shop

Equipment installed in the 4.5-in. shell machining department includes one Bertram radial drill, one Champion lathe, one Putman lathe, one 16-in. American lathe, one 26-in. C.M.C. lathe, and one Rochester high-speed hammer. Three Chapman trucks are employed for transporting the shells about the shop. The varnishing of the shells is done in a special room outside the machine shop, and the varnish baking in a special oven made by the Renton Gibbs Co., Liverpool, England.

9.2-in. Shell Machining

For the machining of 9.2-in. shells, the following equipment has been installed: Two Niles-Bement-Pond 30 in. x 13 ft. 6 in. lathes for finish turning shell bodies; four ditto for finish boring and threading shell noses; one 26 in. Canadian Fairbanks-Morse single purpose lathe or finish boring and threading shell noses; two N.B.P. 30 in. x 13 ft. 6 in. lathes for base counterboring, threading and facing shells to weight; one No. 6 Bertram axle lathe wave ribbing and undercutting; three N.B.P. 36 in. x 20 ft. projectile boring lathes for inside bore of shells; one 36 in. x 14 ft. N.B.P. triple geared lathe for rough turning outside shell bodies; two Bertram lathes for rough turning outside shell bodies; three 26 in. Canadian Fairbanks-Morse single purpose lathes for preliminary rough turning or spotting; three 26 in. C.M.C. lathes for finish turning, etc.

The operations pertaining to the machining of 9.2-in. shells are as follows:—(1)—Cut off open end of forging; (2)—bore and face nose (6 ft. radial drill); (3)—rough turn; (3a)—preliminary rough turn; (4)—rough and finish bore; (4a)—preliminary rough bore; (5)—finish turn body; (6)—finish bore, face and tap nose; (7)—counterbore base, thread and face to weight; (8)—wave rib and undercut; (9)—wash; (10)—shop inspection; (11)—preliminary Government inspection; (12)—turn adapter; (13)—screw in adapter; (14)—press copper band; (15)—turn copper band; (16)—face off base with adapter in position; (17)—enamel interior of shell; (18)—bake enamel; (19)—mark shell; (20)—final shop inspection; (21)—rectify; (22)—final Government inspection; (23)—painting; (24)—boxing; (25)—shipping.

Other important departments and quite extensive contributors to the various production processes, as well as to the upkeep of the various plant structures, and the shipment of finished commodities, are the carpentry, pattern, structural and box-making shops.

The shipping and store room is of ample size to care for all finished products, being 850 feet long and 75 feet in width. This department, in common with the others, is equipped with powerful electrically-operated cranes sufficient to handle the various weights required.

Power Plant

In the power plant, nine Stirling boilers are installed, each of 350 horsepower. Five of the boilers are fitted with Fulton stokers, the remainder being fired by hand. A Williams feed regulator is installed. A Davidson pump, 14-

8¼-14, and a Weir pump supply water through a feed water heater to the boilers from a tank, which in turn is supplied by return water from skid pipes from the various heating furnaces, and from turbines and air compressors. This is supplemented by automatic supply pipe from water service direct. A Williams feed regulator is installed in the system.

In addition to the Stirling boilers there are six Matheson return tubular boilers in connection with the mill furnaces. These supply steam to the mills, also to the old and new power houses.

The old power house contains one d.c. 640 k.w., 230 volt generator, driven by a 150 h.p. Matheson engine.

The new power house contains two d.c. low pressure turbines, and a 500 k.w. Siemens generator of 230 volts, made by Daniel Adamson & Co., Dunkinfield, England.

One Robb engine, and a 50 k.w., d.c. generator of 200 volts, and 220 r.p.m., the latter made by the Canadian General Electric Co.

One high pressure turbine pump of 350 lbs. pressure, driven by low pressure turbine and of 3,200 r.p.m., for accumulator service.

Air pumps and 10 h.p. motor running 850 r.p.m., made by Daniel Adamson & Co., Dunkinfield.

Surface condenser in connection with low pressure turbines, made by Daniel Adamson & Co.

One set condenser for turbine driving high pressure pumps, made by Daniel Adamson & Co.

Three circulating pumps at shore for delivering water to condensers, made by Daniel Adamson & Co. These are driven by 40 h.p. motors running 1,040 r.p.m.

One pump for delivering condensed water to boiler tank; output being 72,000 gallons per 24 hours.

One ventilating fan driven by 7 h.p. motor.

One 5-ton Cleveland crane, operated by chains.

Two air compressors as follows:—No. 4131 with air cylinders of 13-21-36 and steam cylinders of 12-22-36, and No. 1560 with air cylinders of 14-14-22 and steam cylinders of 14-14-22, supplied in each case by the Canadian Ingersoll Rand Co., Sherbrooke, Que.

These compressors supply air to entire plant.

The plant is situated on the Intercolonial Railway of Canada, giving it direct connection by rail to all parts of the Dominion and the United States. Railway sidings extend into the various departments. On completion of the river improvements now in progress, the plant will be on tide-water, and will be accessible to 6,000-ton ships. The buildings cover an area of some 10 acres, and employment is given in normal times to over 1,000 men.

Welfare Work—Trenton Plant, New Glasgow

Every precaution is taken to render safe the working conditions of the men, and to provide first aid promptly to the injured should an accident unfortunately occur. First aid boxes have been provided in the different departments, and a well-equipped first aid room is always kept in readiness for the reception and treatment of those injured. The company also has a comfortable and well constructed ambulance at the plant for the conveyance of sick or injured to the Aberdeen Hospital or to their homes.

The hospital mentioned is modern, thoroughly equipped and manned. It is situated in the town of New Glasgow about two miles distant; and has a most efficient corps of physicians and nurses. Being in the centre of a large mining territory its maintenance is provided for by subscriptions from the workmen, the companies operating in the district, and other residents. From every workman at the steel plant a small monthly subscription is received, and, in return, during sickness or injury, free treatment for the subscriber and members of his family is provided.

A further example of the interest taken by the company in the welfare of its workmen is the Employees' Relief Fund which is administered by a joint committee consisting of representatives of the workmen and the management. A small monthly fee, varying in amount from 15 to 40 cents, is subscribed by every employee, the company adding to the amount a subscription equal to the total sum so subscribed. From this fund, weekly payments are made to a workman during his period of sickness, injury or quarantine, and a cash payment made to the estate in case of his death. It may also be mentioned that rest houses have been installed for the benefit of the men at convenient points about the plant.

Shells Forged to April 30, 1916

18 Pr. Shrapnel	2,933,166
15 Pr. Shrapnel	336,677
Total	3,270,000
4 5 in. High Explosive	1 085.415
60 Pr. High Explosives	105 075
Total	1,200,000

Shells Finished to April 30, 1916

18 Pr. Shrapnel	say 110,000
4.5 in. High Explosive	56,000
60 Pr. High Explosive	7,836

Miscellaneous Outputs, 1915

Coal, 618,103 tons, four coal mines being in operation at present time.

Iron ore mined, 125,069 tons.

Pig iron made, 73,110 tons.

Steel ingots made by Sydney mines, 97,072 tons.

Steel billets rolled, 76,082 tons.

"Scotia's" Shipbuilding Enterprise

In view of the recent utterances of Col. Cantley relative to Federal Government aid to already established and prospective shipbuilding enterprise in Canada, it is interesting to note that, while action along the lines indicated is still more or less an uncertain factor, there is no uncertainty as to what "Scotia" has planned to undertake in the creation of a steel shipbuilding industry in a plant adjacent to its New Glasgow steel mills. A vessel of 220 ft. in length is to be the pioneer of the new enterprise, and not only are the plans prepared, the shipyard surveyed and in process of preparation, the equipment for same ordered and the expert help engaged, but a contract has been awarded for the propelling machinery. The latter will consist of a 1,000 horse-power, De Laval marine type steam turbine, complete with double helical reduction gears, and will constitute the first installation of its kind on a Canadian-built vessel. The propeller speed will be 80 r.p.m. The vessel on completion will enter the "Scotia" Company's general freight service. The De Laval turbines are being supplied through the Turbine Equipment Co., Toronto, and we are advised that they will also furnish the condensing equipment, bilge and boiler feed pumps.

"Scotia" Directorate

The men directing "Scotia" are as might be expected prominent in a wide variety of successful industrial and commercial enterprise as a glance at the accompanying list indicates:—President and general manager, Colonel Thos. Cantley, New Glasgow, N.S.

Vice-president, Hon. J. D. MacGregor, Ex-Lieutenant-Governor of Nova Scotia, New Glasgow, N.S.

Vice-president, W. D. Ross, director Bank of Nova Scotia, Toronto, Ont.

J. Walter Allison, director Bank of Nova Scotia, Eastern Trust Co., Acadia Sugar Refining Co., etc., Hallifax, N.S.

James C. MacGregor, vice-president Eastern Car Co., president I. Matheson & Co., director J. C. Carmichael & Co., New Glasgow, N.S.

George F. MacKay, former manager Nova Scotia Forge Co., New Glasgow, N.S.

Robert E. Chambers, M.I.M.E., manager ore mines and quarries, New Glasgow, N.S.

Frank W. Ross, capitalist, Quebec, P.Q.

Lorne C. Webster, vice-president Quebec Railway, Light, Heat & Power Co., Montreal, P.Q.

Frank Stanfield, M.L.A., director Stanfield's, Ltd, Truro, N.S.

George S. Campbell, director Bank of Nova Scotia, director Eastern Trust Co., Halifax, N.S.

W. H. Chase, Wolfville, N.S.

A. F. Rendall, St. John's, Nfld.

N. Bruce McKelvie, of Hayden & Stone, Boston and New York.

The Man Behind the Industry

Col. Thomas Cantley has been general manager of the company since 1901, and has been with it since 1885. He became second vice-president in 1909 and president in 1915. It is no reflection upon previous managers to say that "Scotia's" greatest development has taken place since he assumed its management, but more of a tribute to his untiring energy and ability.

Col. Cantley was elected first vice-president of the Canadian Manufacturers' Association in 1915, and to be next to the top of such an important organization, with a membership of over 3,000 Canadian manufacturers, is no mean compliment to a man who has worked his way up from the bottom of the ladder. Col. Cantley has taken a leading part in the production of shells for the Allies, was made an honorary colonel in this connection, and is chairman of the Canadian Munition Resources Commission in Canada.

Like many others, of our prominent industrial and business men, the Colonel started his first job when 15 years old, as a messenger with the Western Union, and when the Intercolonial Coal Co., at Westville, built a telegraph system connecting the collieries, railway and wharves with the Western Union system, he became their first telegraph operator. Later, he went into a general merchandise business which he abandoned in 1885 to take up the work of sales agent of the Nova Scotia Steel Co. Step by step, he rose in the estimation of the executive, also in position, becoming in turn, secretary, assistant manager, joint manager, director, and holds the dual appointment of general manager and president of the company. He is a practical man in every sense of the term having not only a thorough knowledge of the steel industry, but what is equally important, of his company's position and possibilities.

Col. Cantley was born in New Glasgow, N.S., and not believing that far away fields only are green, stayed in Nova Scotia. He has probably half-a-dozen suit cases well spattered with labels, as he has spent much time in Great Britain, Germany, Norway, Sweden, Austria, Italy, France, Cuba and other countries. Between 1895 and 1900, he introduced Wabana iron ore abroad, more than 2,000,000 tons being so exported. That trade having ceased on account of the war, Col. Cantley has been hustling with the typical enterprise of the maritime province people, to find new export markets and openings for the products of his progressive corporation.

Col. Cantley has several valuable helpers, other than those on the directorate. A. McCall, secretary commercial manager, has been with "Scotia" for over a score of years, and is familiar with every phase of its commercial activities. Major Cantley, who spent about eleven months with his regiment, the Fifth Royal Highlanders, somewhere in France, was recalled by the Minister of Militia and seconded for special duty in connection with munition work. Since his return, he has been responsible for all munition work of the "Scotia," in addition to filling the position of assistant general manager of the whole enterprise. H. B. Douglas is manager of the Eastern Car Co., and has his end of the business in excellent shape to handle the large orders which are expected in the future. During the past year, Mr. Douglas and his men have been busy in filling orders for cars for the Russian and French governments.

Directors' Report—Year 1915

At the annual meeting of shareholders of the Nova Scotia Steel & Coal Co., held at New Glasgow on March 20, the directors submitted the fifteenth annual report and statement of assets and liabilities, with abstract of profit and loss, for the year ended December 31, 1915.

Col. Cantley in dealing with the operations of the preceding year, 1916, said that during the past 30 odd years in which he was privileged to be connected with the Scotia Company, the corporation and its management had passed through some anxious and trying periods, but in all his experience he could not recall a year where the issues involved in the fluctuations and departure from normal conditions were anything like so great as during 1915.

Of the staff and other employees of the company there have volunteered for military service in various units, 721 men, while a considerable further number are enrolled in the permanent Canadian militia. These figures are equivalent to about 40 per cent. of those in the employ of the company of military age, and it is doubtful if any corporation in Canada has provided a larger number of recruits in proportion to its staff.

The company has made considerable sacrifice in this loss of officers and men, but the policy of the board has been that, although the management is being hampered and the operations of the company greatly handicapped, no restrictions should be placed in the way of enlistments. On the contrary, soon after the outbreak of war it was by a formal resolution of the board decided that all employees of the company volunteering for service in the armies of the Empire or the Allies should on their return from active service be again given employment by the company, even should it necessitate the retirement of others who had entered the company's service subsequent to that date.

The year 1915 brought to the management and staff, particularly at New Glasgow, many new problems and made heavy demands on the operative engineering and executive staff, many of whom worked long hours under heavy pressure and are entitled to very great credit for the character of the service rendered and the success attending same. A strong feeling of optimism prevailed among the large number of shareholders present and they were not only enthusiastic about the outcome of the past year, but looked forward with an eye of optimism toward what the future has in store for their well-managed and well-equipped organization.

The accompanying table shows the ore shipped by "Scotia" from the Wabana mines from 1895-1915:—

Year.	Tons per year	Tons to date
1895	2,400	2,400
1896	35,900	38,300
1897	45,387	83,687
1898	101,127	184,814
1899	302,784	487,598
1900	127,791	615,389
1901	342,638	958,027
1902	422,906	1,380,933
1903	343,227	1,724,160
1904	245,933	1,970,093
1905	308,044	2,278,137
1906	387,841	2,665,978
1907	346,496	3,012,474
1908	312,795	3,325,269
1909	460,387	3,785,656
1910	516,651	4,302,307
1911	516,334	4,818,641
1912	484,472	5,303,113
1913	623.037	5,926,150
1914*	249,957	6,176,107
1915*	190,060	6,366,167

*Shipments during these years were reduced on account of the war.

The directors are each of them men of ability and enterprise and are well known in Canadian business and financial spheres. The future success of Scotia will more than anything else depend as in the past on the calibre of the men who manage its affairs, and just at the moment there is little likelihood of any backsliding making itself evident. The outlook for the remainder of the present year, at least is of the brightest possible description.

Icebreaker Launch Marks St. Lawrence Navigation Epoch

Staff Article

Just to what extent the work of the new and powerful ice-breaker "J. D. Hazen" will be able to compress the ice-bound season of navigation on the St. Lawrence River is at present more or less problematical. Her advent is, however, a step in the right direction, and, if followed up, cannot fail to effect in the direction indicated a very material improvement on the conditions hitherto existent on that great highway of trade and commerce.

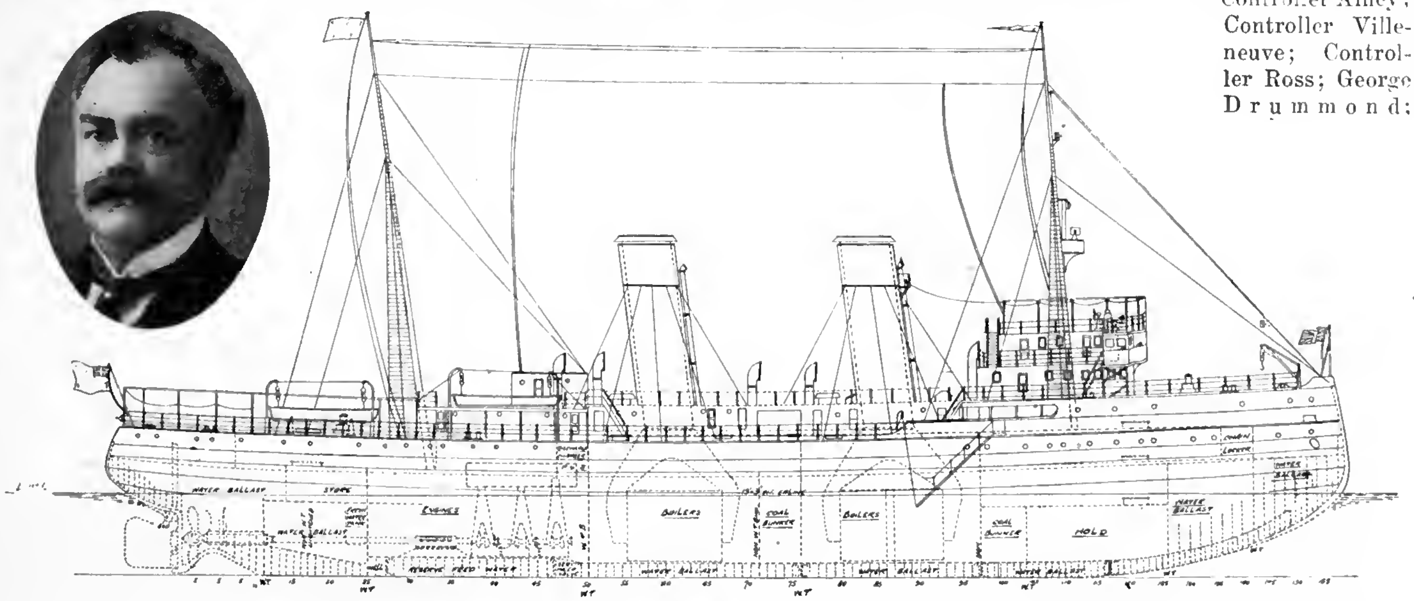
THE launch of the Dominion Government icebreaker, J. D. Hazen, on Monday afternoon, May 15, from the shipyard of Canadian Vickers, Montreal, was an event of more than ordinary importance. True it is that the major significance attaching to it appealed particularly to the residents of our Metropolitan City, and to those of the cities and townships located on and about the shores of our great ocean highway—the St. Lawrence River. Notwithstanding, the circumstances were such as to produce a stimulating effect even now as in the days to come, on the whole agricultural, industrial and commercial life of this far-flung Dominion.

LADY BORDEN,
Wife of Canada's Prime Minister, and who christened the vessel.

The building and conspicuously successful launch of the J. D. Hazen in this war time, when other and just slightly more urgent service commodities must be given preference, is an achievement of which the builders may well be proud. Further it should be remembered that steel shipbuilding and marine engineering have never been over-robust in Canada—thanks in large measure to lack of interest, because lack of intelligent appreciation by responsible governments of not only our national requirements in the matter but of the latent possibilities in our manhood awaiting the opportunity to achieve something worth while in a world sense in these two spheres. Lack of skilled labor due to the intermittent nature of shipbuilding within our borders has always had to be contended with, and in recent months has become trebly acute through the absorption of our manhood for overseas Empire military service.

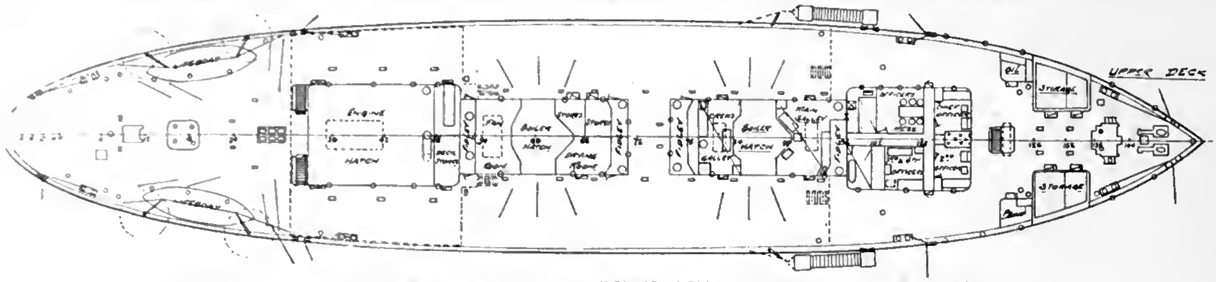
As befitted the occasion, the launch of the first real seagoing ship, not only from the plant of Canadian Vickers, but from the port of Montreal, a large and influential party of ladies and gentlemen was present on invitation of the vessel builders, among whom we noticed the following:—

Sir Robert and Lady Borden; His Honor the Lieutenant-Governor of Quebec and Mrs. LeBlanc; Mr. and Mrs. W. G. Ross; Ald. Hushion, representing the Mayor of Montreal, and Mrs. Hushion; Chief Justice Archibald; G. Bury, vice-president Canadian Pacific Railway; Brig-General Sir Alexander Bertram; Lady Williams-Taylor and Miss Brenda Williams-Taylor; D. Lorne McGibbon; Jas. Carruthers, director Can. Vickers; R. C. Smith, K.C.; Aime Geoffrion, K.C.; Mrs. R. Chaplin, Brig- General and Mrs. E. W. Wilson; Mr. and Mrs. J. G. Lewis; Sir Charles Gunning; Hon. and Mrs. C. J. Doherty; Serge de Liktascheff and Madame Liktascheff; Senator and Mrs. J. P. B. Casgrain; C. C. Ballantyne; Smeaton White; Miss de Salaberry; Mrs. G. W. Cook; J. W. McConnel; F. Orr Lewis, president Canadian Vickers; Brig-General A. E. Labelle; Farquhar Robertson; Mayor Seath; M. P. Fennell, jr.; Ludger Gravel; J. N. Cabana; Dr. W. H. Atherton; Dean Adams; Sir Herbert Holt; S. W. Ewing; ex-Controller Wanklyn; Hon. Jeremie Decarie; Sir William Petersen; Controller Ainey; Controller Villeneuve; Controller Ross; George Drummond;



CANADIAN GOVERNMENT ICEBREAKER "J. D. HAZEN," WITH PHOTO OF MINISTER OF MARINE AND FISHERIES INSET.

Hon. W. S. Fielding; ex-Ald. L. A. Lapointe, M.P.; Colonel Starke; P. V. G. Mitchell; W. G. Annable; Captain

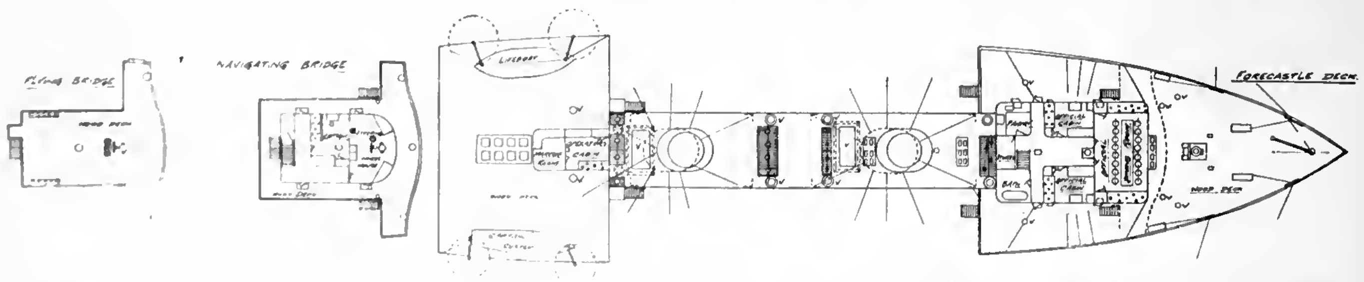


GENERAL ARRANGEMENT OF UPPER DECK, ICEBREAKER "J. D. HAZEN."

Bourassa; Lieut.-Col. Magee; Robert Reford; F. J. McClure; W. A. Coates; Sir John Kennedy; Ald. W. G. M. Shepherd; P. L. Miller, shipyard manager, Can. Vickers; Edgar McDougall; Herbert Ewan; Mr. and Mrs. J. H. Rodgers; John S. Leitch, Collingwood; O. E. Champagne; James French, New York, principal surveyor of Lloyd's Registry, United States and Canada; H. Driver, Secy. Can. Vickers; Thomas Hall; Cecil Doutre, commercial manager Can. Vickers, and Peter Bain, editor Marine Engineering of Canada, etc.

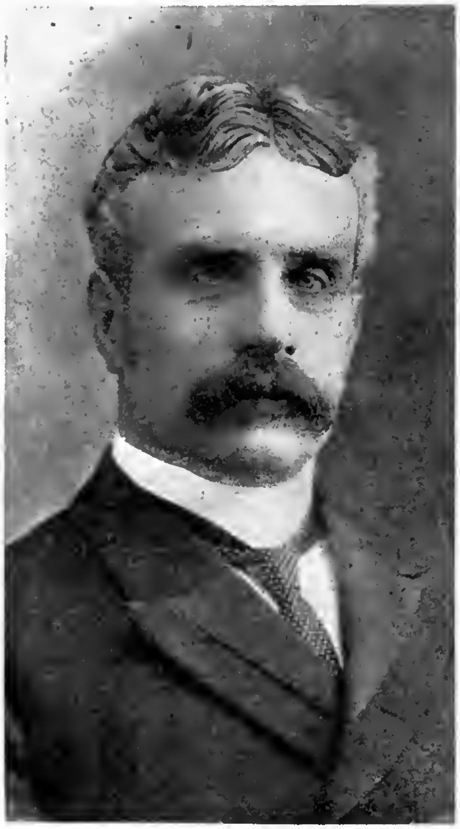
Lady Borden, wife of Sir Robert L. Borden, Canada's Prime Minister, performed the christening ceremony as the vessel began to move towards her native element, the ease and grace with which the little function was marked being indicative of the vessel's part in taking the water a few seconds later. Immediately following the launch, the J. D. Hazen was taken alongside the builders' wharf to receive her engines and boilers and be fitted out for service, the invited guests in the meantime adjourning to the shipyard molding loft which had been tastefully decorated for the occasion. Here refreshments were served, and some more than usually significant speeches made by F. Orr Lewis, president, Canadian Vickers, and by Sir Robert L. Borden, our Prime Minister.

Mr Lewis pointed out the now exceptional opportunity for Canada to start on the way to become a great shipbuilding nation, and the Premier in his response stated it was the policy of the Government to lend every reasonable assistance in competing with the long-established yards of older countries, including the United Kingdom.



GENERAL ARRANGEMENT OF FORECASTLE DECK, FLYING AND NAVIGATING BRIDGES, ETC., ICEBREAKER "J. D. HAZEN."

At the end of Mr. Lewis' address, he presented Lady Borden, as a souvenir of the occasion, with a gold neck chain, to which was attached a specially large diamond. Lady Borden made graceful acknowledgement of the gift.



RT. HON. SIR ROBERT L. BORDEN,
Who was present at the launch and spoke at the reception following.

F. Orr Lewis in his address reminded his auditors that a few years ago the site of the building in which they were gathered had been a part of the River St. Lawrence, from which more than 36 acres had been reclaimed by dredging.

He thanked Sir Robert and Lady Borden for coming, and paid a tribute to the present and previous Ministers of Marine and Fisheries, to the present and previous harbor commissioners and engineers of Montreal, and to P. L. Miller general manager, and his staff, for the zeal and great ability which had marked the construction and launch of the new icebreaker. He spoke of the work already accomplished by the shipyard plant in repairing one of His Majesty's cruisers, and in constructing ten other important vessels in a shorter time than had ever before been known.

Mr. Lewis pointed out that Canada has (potentially at least) in her steel, coal and timber all that is necessary to enable her to rival the results of which the Americans are so justly proud. Preparations he said should be made immediately to secure for Canada a portion of the enormous shipbuilding business which, as a result of war, will go to those ready to undertake it. After the war would be too late. John Leyland had placed the loss of British tonnage since the war began at 3,300,000 tons of all denominations.

"It is perhaps an open secret that when this yard was established, it was with the undertaking that as soon as we were ready we would have the building of naval ships," said Mr. Lewis. "Our alliance with one of the greatest, if not the greatest, shipbuilding companies in the world places us in the most favorable position to undertake the work, and if naval and commercial shipbuilding could proceed side by side, there is no doubt that within a short period of years the question of price, as between Canada and the older countries who have been building ships for generations past, would be satisfactorily solved."

Premier's Speech

Sir Robert Borden in his speech referred to the great war as one not only between armies engaged but between the industrial resources of the Allies and those of the Central Empires. In both capacities Canada had surpassed not only the expectations of her people, but the expectations of the world outside. After eulogizing what Canadians had done on the battle field, the Premier also praised the patriotism, skill and adaptability of those who organized Canadian industries and managed them so that they have been of such benefit to the Empire.

"The ship which has just been launched to-day is an example of the efficiency of these works," said the Premier, "and also of their scope and the efficiency of the management. I congratulate most sincerely not only the company, but the whole Canadian

Nova Scotia. He saw no reason why Canada should not go forward to the undertaking of building steel ships, and why she should not rival in the future the record made by Nova Scotia in the past in building wooden vessels.

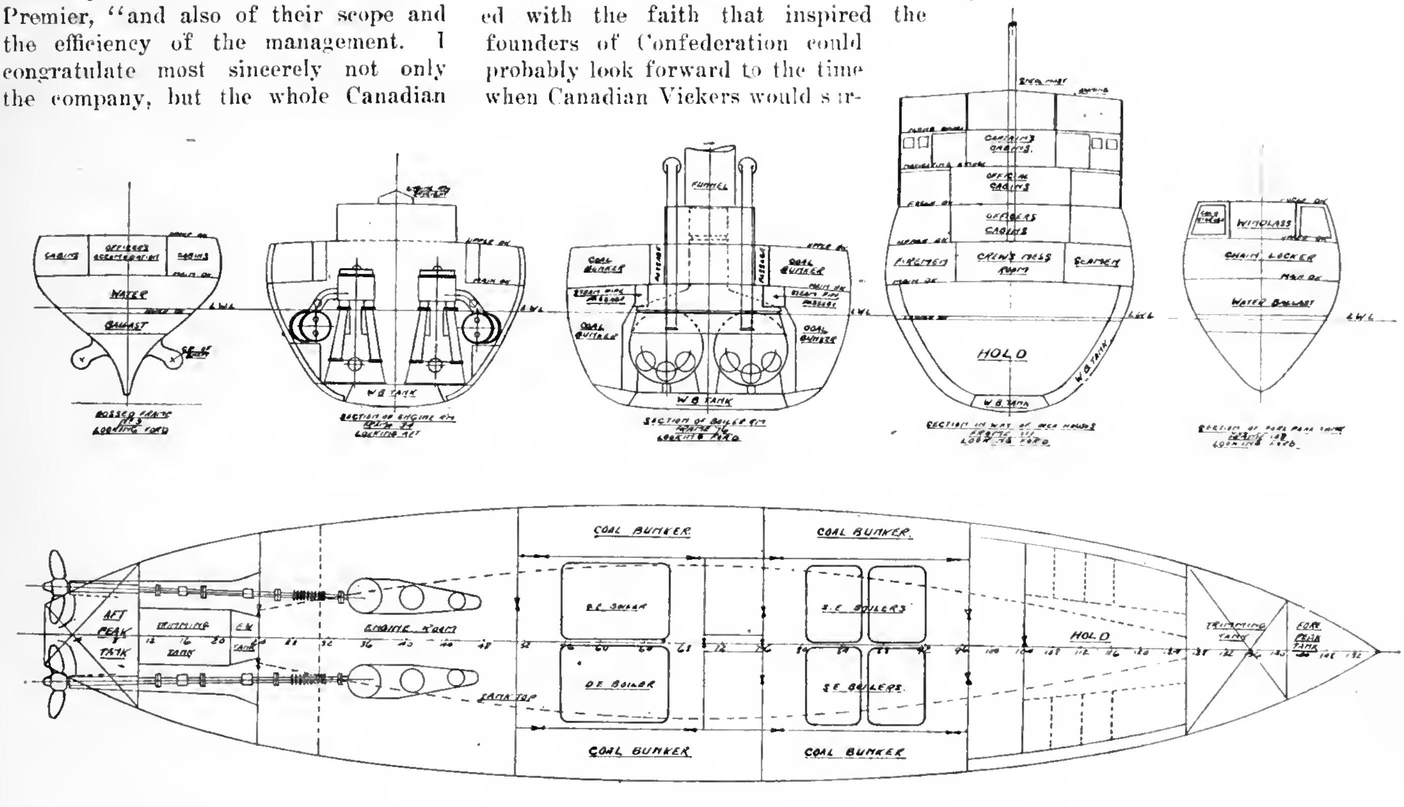
Sir Robert quoted a remark made to himself in Great Britain by the manager of one of the greatest shipbuilding concerns there, that, as the years roll by, the cost of building steel ships in Canada will more and more approximate to the cost in the United Kingdom.

"One man told me," said the Premier, "that in the next twenty years the cost in Canada will not be greater than the cost in the United Kingdom."

The Premier said that those inspired with the faith that inspired the founders of Confederation could probably look forward to the time when Canadian Vickers would sur-

war occur. He thanked Mr. Lewis for the splendid example given Canadians as to what could be accomplished with Canadian resources, coupled with the experience and knowledge which had been built up through such a long period in the United Kingdom. He referred, in closing to the hope of all that victory would come soon and that the preservation of the liberty and institutions of Canada, the Empire, and the world would be assured by a peace at once honorable and triumphant.

Hon. C. J. Doherty, Minister of Justice, thanked the Canadian Vickers, Co., for the opportunity afforded those present of seeing a noteworthy event in Canadian annals. Mr. Orr Lewis responded briefly.



HOLD PLAN AND SECTIONAL ELEVATIONS OF ICEBREAKER "J. D. HAZEN."

nation that this ship has been turned out in the short time available. I believe she has been on the stocks some time, but the work on the ship launched to-day had to be postponed for important reasons which may not be mentioned here. It is possible that this ship may be applied to some purpose connected directly or indirectly with the carrying on of this war and the furnishing of supplies. If such should be the case, and indeed in any case, the company are to be congratulated for a work which will be in the cause of Empire and the Allied Nations."

Referring to Mr. Lewis' remarks on shipbuilding, Sir Robert spoke of the ancient pre-eminence of Canada in this regard, more especially to what had been done in his native province of

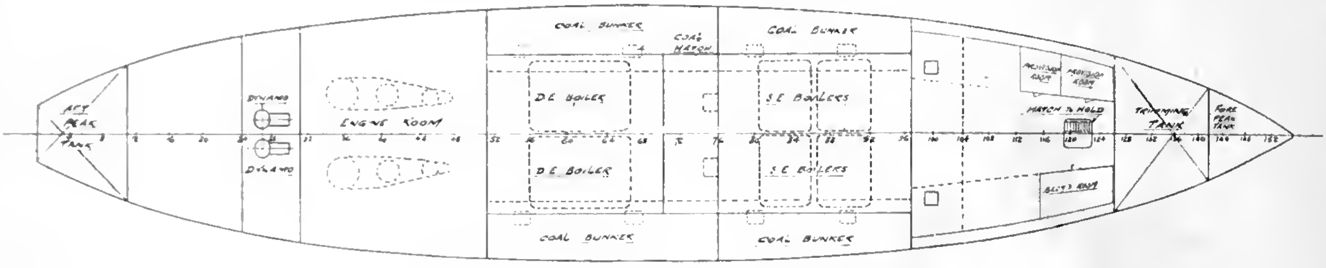
pass the parent from which it had sprung and when Canada would have a shipbuilding industry equally as great as that in the United Kingdom. "I am sure that both political parties are thoroughly in sympathy with that development," said Sir Robert, "and I am absolutely confident that both political parties in Canada will be willing to pledge themselves to give all reasonable assistance to help bring about that end."

The Premier then pointed out that other enterprises would derive benefit from a flourishing shipbuilding industry the requirements for building, fitting out and commissioning a vessel being many and varied. The development here of a large shipbuilding industry would also be a great asset to Canada and the Empire should another great

In addition to those specially invited to the launching ceremony and subsequent reception, and who were conveyed to the shipyard by special train on the Harbor Commissioners railway tracks from the foot of McGill Street, several thousand more or less privileged people were admitted to points of vantage inside the shipyard from which a view of the icebreaker as she glided into the water could be comfortably had. Work in every department of the plant ceased at noon on the day of the launch to give the employees opportunity of being present at the unique function. A pleasing feature of the arrangements made for taking care of and giving guidance to the invited guests and others was the distribution of 85 members, 53rd Montreal Boy Scouts

(Vickers troop) under command of Scout-Master Costain, along the line of approach to the vessel while on the ways, and to the reception hall. Sixty of the boys are employed at the works, and the majority are sons of employees as well.

On conclusion of the whole proceedings the invited guests were taken by

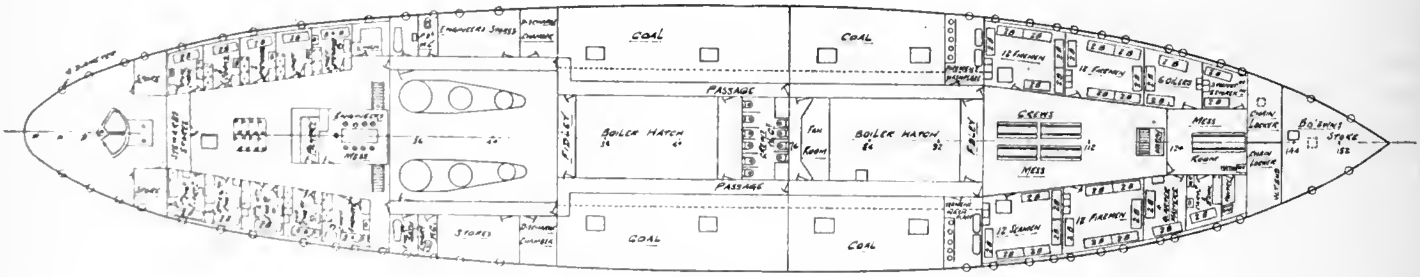


LOWER DECK PLAN, ICEBREAKER "J. D. HAZEN."

train to the opening ceremony in connection with the extension to Harbor Commissioners Elevator No. 1, concerning which an account is given elsewhere in this issue. It should also be added that each invited guest, during the reception proceedings was the recipient of a handsomely illustrated souvenir booklet, briefly descriptive of the new icebreaker.

Vessel Particulars

The hull, as is usual in vessels of this type is of extra strong construction, every advantage having been taken of the wide experience possessed by the builders to insure satisfactory service under exceptionally severe conditions. The vessel is intended for ice-breaking purposes only and will probably be laid up during the open season. Steel construction is adopted throughout the hull which is sub-divided into watertight compartments by seven transverse bulk heads to the height shown in profile. The hull bottom is of the double cellular type, and extends from frame 25 to frame 126, the space being used



MAIN DECK PLAN, ICEBREAKER "J. D. HAZEN."

for carrying water ballast, a portion of which, however, of about 90 tons capacity is reserved for feed water storage purposes.

The stem is formed of a massive steel casting, raked aft, and the stern is of the cruiser type which facilitates navigation amongst ice. Complete equipment is provided for pumping purposes, each compartment being fitted with steam and hand operated pumps. The rudder frame is an extra heavy steel casting, while the trunk is of .46 in. steel plate securely riveted to the stern framing, with cast steel stuffing boxes having brass glands. All side plates are 20 lbs. per sq. ft., the inner space being filled with well—seasoned fir closely fitted and bedded in white lead.

Watertight construction is used in the side bunker walls to the height of the upper deck, these, with the inner skin between the forepeak and the forward bulkhead, forming a double skin extending aft to the boiler room bulkhead. A 10 ft. deep ice belt is fitted at the water line, extending the entire length of the hull, the thickness forward being $1\frac{1}{8}$ in., and 1 in. aft. Plating of $1\frac{1}{8}$ in. thickness is used in the forward part of the hull while from the bottom of the ice belt to the keel plate for some distance aft, a 1 in. thickness is used.

Success to the "J. D. Hazen" and all who sail in her. May she prove a credit to her builders and to Canada, the land of her birth. —Lady Borden.

Two steel masts are fitted, the topmasts being of Oregon pine telescoped, and the whole supported by wire ropes galvanized and covered.

Propelling Machinery

Two sets of triple expansion surface condensing engines are fitted, the cylinder diameters being 28 in. 46 in. and 75 in. x 48 in. stroke. The valve gear is of the double eccentric link motion type, all wearing surfaces being extra large and well lubricated.

Forged steel is employed for all moving parts such as valve spindles and eccentric rods, while the connecting rods are of extra heavy construction to withstand the stresses resulting from shocks during ice-breaking operations in winter.

Particular attention has been given to the crank shafts which are forged from "fluid-compressed" steel, the webs being shrunk on to the shafts and crankpins, and secured by turned dowels driven half into webs. Each complete shaft is composed of three interchangeable lengths, connected by solid flanged couplings; the thrust and propeller shafts are of similar material. All working parts of the machinery possess a degree of strength varying from 35 per cent. to 60 per cent. in excess of Lloyds' requirements.

Boilers

These are of the Scotch type, two being double-ended and four single-ended units of 15 ft. 6 in. diam., the former 21 ft. and the latter 12 ft. long. The total heating surface amounts to 21,900 sq. ft. and the grate area, 560 sq. ft. The boilers operate under forced draft, and supply steam at a pressure of 180 lbs. per sq. in. enabling the engines to develop 8,000 indicated horsepower when running at a speed of 100 revs. per min. The bunker capacity is designed for 1,300 tons of coal.

Auxiliary Equipment

A complete electrical installation is fitted, the 110 volt, A.C. generator being in duplicate, and driven by compound high speed engines, running 500

revs per min. A 24 in. searchlight is provided for observation purposes, and a wireless equipment is to be installed by the Canadian Marconi Co.

Engine room communication with the navigation bridge is provided by Chadburn's (Ship) Telegraph Co., the instruments being of the latest type: illuminating, repeating, and tell-tale.

Ventilation, steam heating, hot and cold water services throughout are provided to withstand rigorous climatic conditions. Four 26 ft. lifeboats and one captain's cutter provide life-saving apparatus in compliance with law, for the ship's crew of 90 officers and men. Engineers' and stewards' quarters are on the main deck, the crew and petty officers being quartered on the forward part of the same deck, while officers' quarters and mess-room are located at the forward end of the upper deck casing.

Dimensions

Following are the principal dimensions of the vessels:

Length overall	292 ft.
Length between uprights	275 ft.
Breadth moulded	57 ft. 5 in.
Depth moulded	32 ft.
Draft mean	19 ft. 3 in.

Deadweight on above draft with coal stores and crew, about 950 tons.

ICE-BREAKER LAUNCH PROMPTS SHIPBUILDING AID DEBATE

ON a motion to go into supply in the House of Commons, Ottawa, on May 16, E. M. MacDonald, of Pictou, brought up the question of shipbuilding in Canada. He referred to the statement of Sir Robert Borden at the launching of the new ice-breaker at the Canadian Vickers yard, Montreal, that the Canadian Government favored subsidizing the shipbuilding industry. It was not so long ago, said Mr. MacDonald, that the idea of building of steel ships in Canada had been proclaimed an absurdity by the Government. Now it had been demonstrated that as Canadian manufacturers could make shells, submarines and ice-breakers, in like manner they could make steel ocean-going vessels. The Pictou member did not favor assisting the construction of wooden vessels. In conclusion, he pointed to the present scarcity of tonnage as a reason for the immediate encouragement of shipbuilding, and said he had no doubt the scarcity would for a long time exist after the war was over.

Sir Robert Borden replied that he was not aware that Canada's ability to build steel merchant ships had ever been questioned. A country with Canada's resources must ultimately engage in the construction of steel ships. Mr. MacDonald had appeared to confuse the development of a Canadian shipbuilding industry with the present scarcity of tonnage due to the war. Sir Robert said that he had found no one in Canada prepared to construct steel ships within a period which would render them useful in the present condition of vessel scarcity. He doubted whether it would be any advantage to begin the construction of steel vessels now when the cost was at its peak, in view of the fact that they would not be available when tonnage was most needed. After the war was over, the Prime Minister thought, there would be less cargo for vessels to carry, and owing to the release of vessels now interned there would be many more ships to carry it. Sir Robert said he had been informed that the cost of building steel ships in England and Canada would in twenty years be approximately the same.

Hon. Wm. Pugsley said that Canada ought to proceed at once to encouragement of shipbuilding, but unlike his confrere from Pictou, he was in favor of assisting the construction of wooden vessels.

Sir Thomas White said that the tariff had evidently been framed to help the shipbuilding industry, but a protective tariff would not be sufficient. There would have to be a bounty extending over a period of years. The encouragement of shipbuilding was much to be discussed, but it seemed at the present time that if shipbuilders were not now encouraged by the present high prices and high freights to construct vessels they would not be by a bounty. The Finance Minister said that the Government was entirely in sympathy with the idea of encouraging shipbuilding in Canada and of adding vessels to Canada's merchant marine.

Sir Thos. White, answering a question of Mr. Macdonald, said the War Measures Act was wide enough to allow the Government to deal with that part of the problem which had reference to the shipping situation.

F. ORR LEWIS, PRESIDENT CANADIAN VICKERS, LTD.

ADMINISTER HALF THE WORLD'S SHIPPING

IN the House of Lords recently Earl Curzon said that the Government is now administering the entire British mercantile marine, amounting to half the gross tonnage of the world. Forty-three per cent. of British tonnage has been requisitioned for naval and military purposes; 14 per cent. is carrying foodstuffs and raw material on behalf of the Government and its Allies, and the remaining 43 per cent. is being operated by British owners under State regulations.

U. S. TRADE WITH AUSTRALIA

PHILLIP B. KENNEDY, director of the Department of Trade and Transportation at New York University School of Commerce, has been appointed Commercial Attache from the United States to Melbourne. The main object of Mr. Kennedy's work will be to foster a friendly spirit between the United States and Australia, and to help as much as possible to keep the commercial relations on a sound footing. Speaking to a press representative, Mr. Kennedy expressed the view that the United States was exceedingly friendly to Australia. America had watched Australia's part in the war with the greatest admiration, and had taken much interest in her national schemes, particularly in the training of cadets, which he believed would be copied in the United States.

The Eastern Car Co.

New Glasgow N.S.

STAFF ARTICLE

The directors of Nova Scotia Steel & Coal Co. some three or four years ago noted that Canada's demand for railroad rolling stock was increasing faster than its car-building capacity. Further, as keen business men they saw, in addition, that a car construction plant in close alliance with "Scotia" could not fail to provide a good customer for their various steel products. As a consequence, they decided to promote and establish the Eastern Car Co., the plant and equipment of which at New Glasgow, N.S., together with the variety product turned out, form the subject matter of the accompanying article.

THE enormous amount of railway construction which has taken place in Canada in recent years, and is still progressing, although curtailed to some extent on account of the war, not only as to the main trunk lines of the three trans-continentals, but also as to their double trackings and the intricate network of branch lines, which is gradually altering the agricultural and industrial features of the entire Dominion, necessitates a very large amount of rolling stock material. The opening up of new territory and the consequent increase of trade and population, each contribute to a brisk demand for rolling stock.

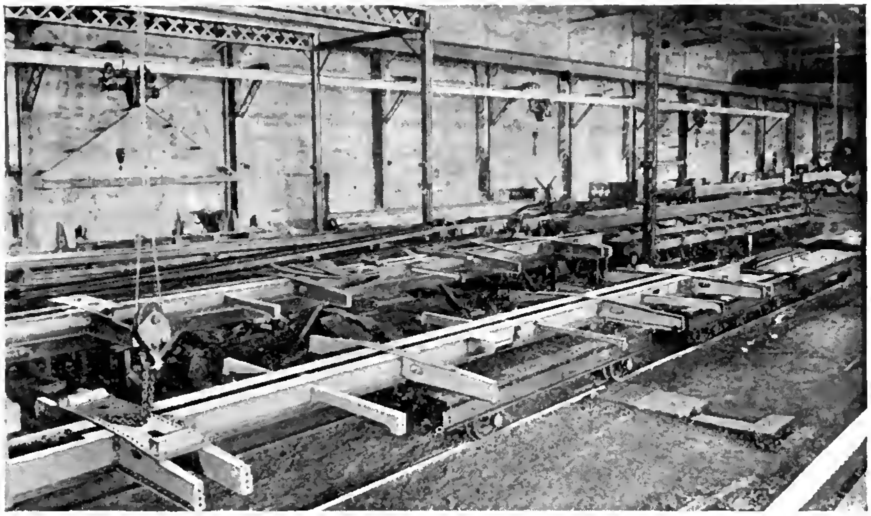
The Eastern Car Co. began operations in September, 1913, and since that time has developed a system of manufacturing capable of producing 40 cars daily. The market for these cars—at home and abroad—is easily capable of absorbing the entire output. Freight cars of all types in wood and steel are being produced.

The company is a subsidiary of the Nova Scotia Steel & Coal Co., the properties of the two concerns being adjacent to each other on the banks of the East River at New Glasgow, N.S. The recent improvements on this river enable ocean-going vessels to land direct at the company's wharf, giving them excellent shipping facilities by both rail and water. The plant was designed and constructed by Horace H. Lane, consulting engineer, Detroit, Mich., who had an organization on the work until the whole was in complete operation. The site embraces some 65 acres.

GENERAL OFFICES, EASTERN CAR CO., NEW GLASGOW, N.S.

Material Handling Efficiency

There are few engineering institutions in which so great a variety of heavy material is handled in such large quantities as in a freight car plant; therefore, to be efficient, everything must



FREIGHT CAR BODY ASSEMBLY DEPARTMENT.

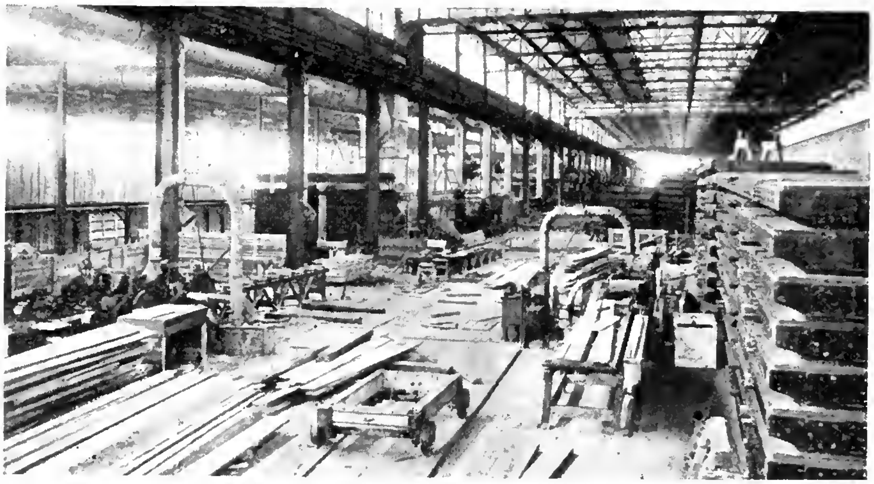
be so arranged that the various materials travel forward steadily from the time they enter the plant until they emerge in the finished product. In some plants the various parts of a car are made in separate buildings, and taken from there to the erection shop, where they are assembled. Some parts, however, go to two or three different buildings before reaching the final assembly.

In this plant it has been aimed to eliminate as far as possible the unnecessary transportation of material and the different departments are for this reason largely centered under one roof, this having the additional advantage that work is not so much affected by weather conditions as it would be with the departments in a number of separate buildings.

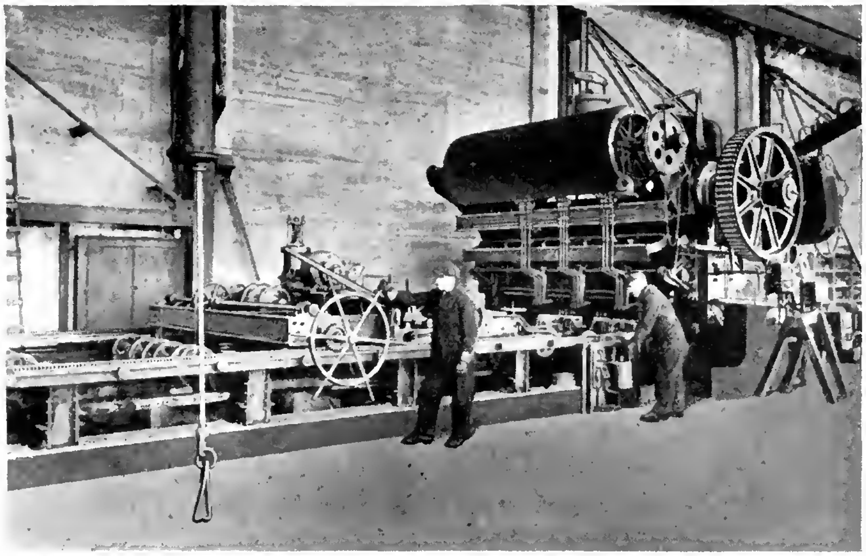
The shops in which the cars are built are the last word in industrial construction as to light, air, warmth and, as already stated, convenience of arrangement. They consist of four parallel buildings, each 1,100 ft. long and 90 ft. wide, all of steel, with concrete foundations and reinforced concrete walls. The storage yard for steel, lumber and other material is at the west end of the plant, the material travelling towards the other end, from whence it emerges as a finished car any type.

The first span contains the air brake, forge, bolt and rivet machine and truck departments, and the general stores, the arrangement being such that the wheels, axles, forgings and other materials for trucks move comparatively short distances until they are assembled, the finished trucks coming out at a point very close to where they are used on the erecting tracks in the next span.

The second span is devoted entirely to the steel department, and contains the shearing, punching, pressing and riveting departments, arranged practically in the order named. The material when brought into the shop is first sheared, then punched and pressed, after which the various units and small parts are assembled and riveted as far as possible before going to the erecting tracks where they are assembled in the completed car. Here again the "progressive" plan is used. The trucks are placed on the erecting track and the main members of the underframe are placed upon it and bolted together. The car then moves to the next "station," where another gang of men proceed with the riveting and further assembling, and so it proceeds from one station to another until by the time it reaches the end of the shop, the steel work is completed. If the car is not an all-steel car, it is then transferred to the next span where the wooden superstructure is completed. The railroad tracks on which the cars are built are located here, and in connection with each track there is an overhead runway, on each of which are located twelve 5-ton hoists, or two hoists for each successive position reached by every car as it approaches completion.



PLANING MILL WITH CAR UNDER-BODIES IN FOREGROUND.



WILLIAMS-WHITE AUTOMATIC PUNCHING MACHINE.

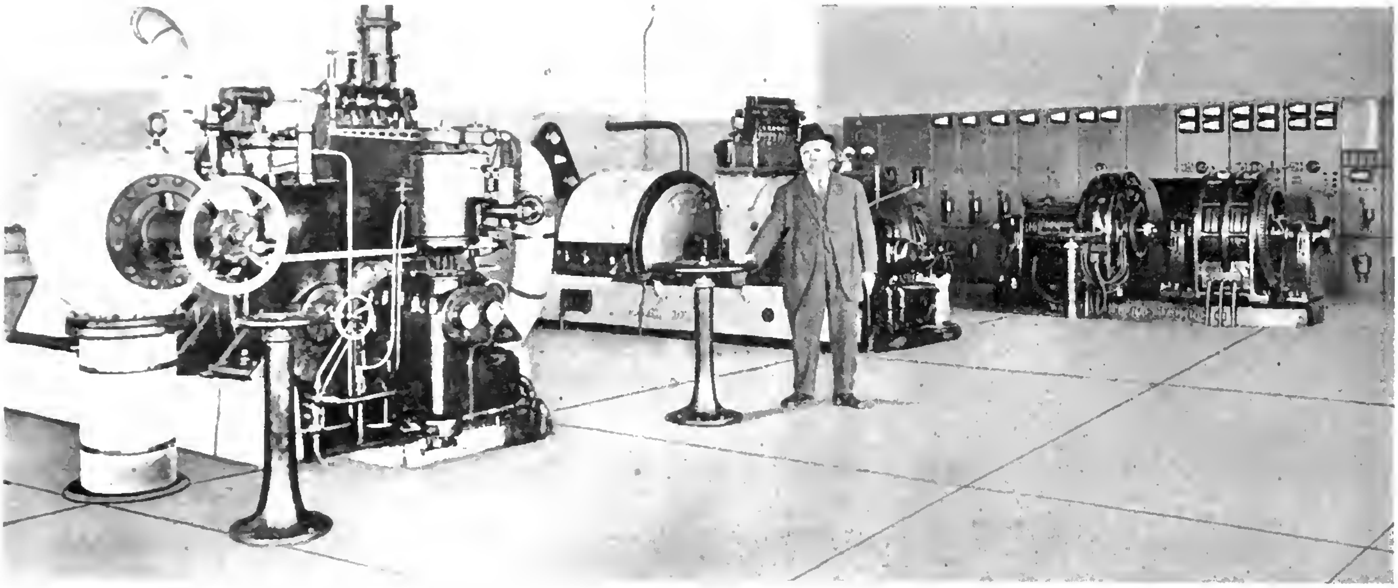
The third and fourth span are taken up with wood-working machinery and wood car erection; the foremen's offices, tin shop, pattern shop, electrical and other maintenance departments are located in the fourth span. The floors of each of the three last-mentioned buildings are controlled throughout the whole length by two 10-ton cranes. There are two in the wood car shop, three in the

steel car shop, and two in the truck and forge shop. The central power house provides current for the electrically-driven machines throughout the plant, also power for the hydraulic presses at a pressure of 1,500 lbs., and compressed air of 200 lbs. per square inch.

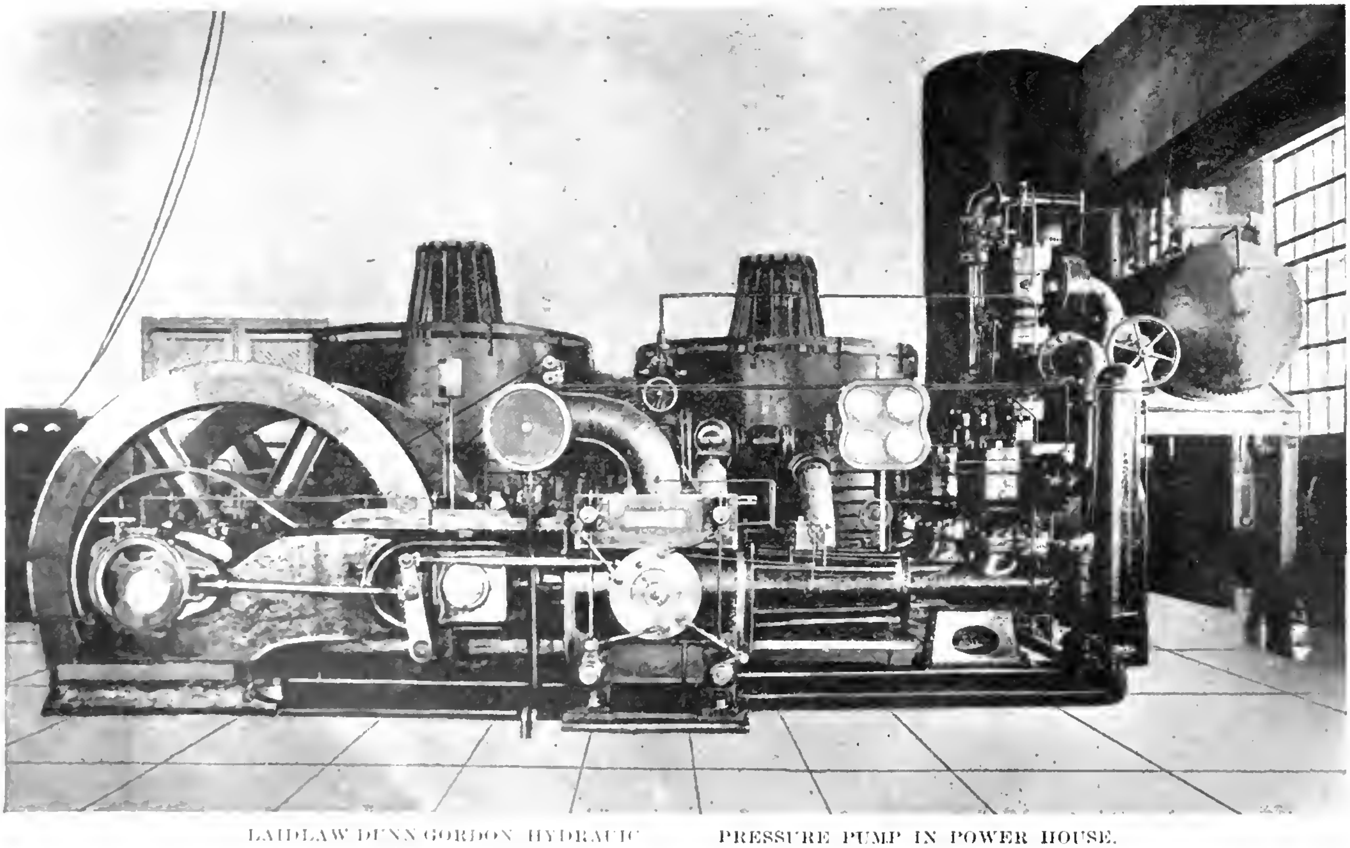
General Equipment

The entire equipment has been selected with a view to building any type of wood or steel car, special attention being given to the heavy steel underframe type which is being so universally used, the heaviest class of automatic machinery being installed for this work. For example, four large Thomas automatic spacing tables and Williams White punching machines are provided. These will punch sheets up to 10 feet wide and 50 feet in length, automatically without any template or pattern, producing the work with greater accuracy and rapidity than can possibly be done by hand. Two R. D. Wood hydraulic presses are installed of 300 and 500 tons capacity, provision being made for a third to be installed later. Most of the machine tools were furnished by John Bertram, Sons & Co., Dundas, Ont., and Canada Machinery Corporation, Galt, Ont.

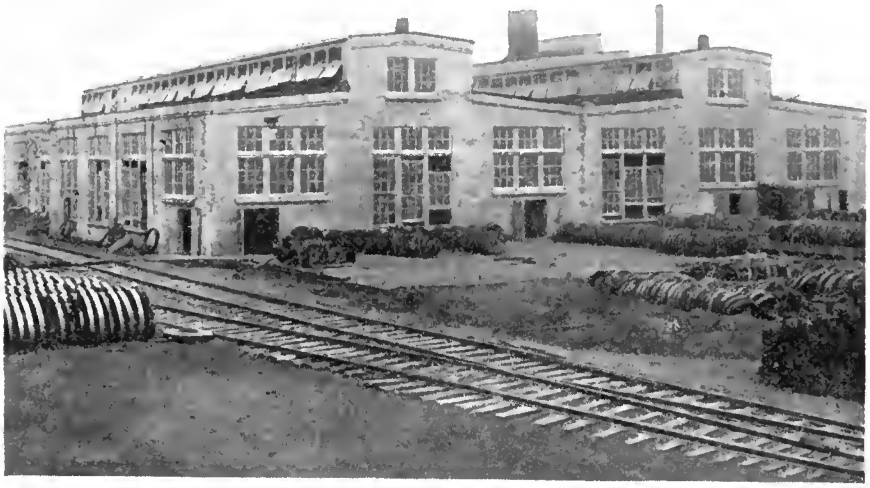
All machines so far as possible are individual motor driven, electricity being used wherever convenient. Very few air hoists are employed, nearly all of the work being done by electric hoists. In order to handle material between the different shops, two outside crane-runways, for operating across the end of the four



INTERIOR OF POWER HOUSE, SHOWING TWO 750 K.W. TURBO-GENERATOR SETS, THE 200 K.W. MOTOR GENERATOR SET, AND MAIN SWITCHBOARD.



LAIDLAW-DUNN-GORDON HYDRAULIC PRESSURE PUMP IN POWER HOUSE.



EXTERIOR VIEW OF CAR WHEEL AND GREY IRON FOUNDRY DEPARTMENTS.

buildings, have been provided and equipped with 10-ton Shaw electric cranes.

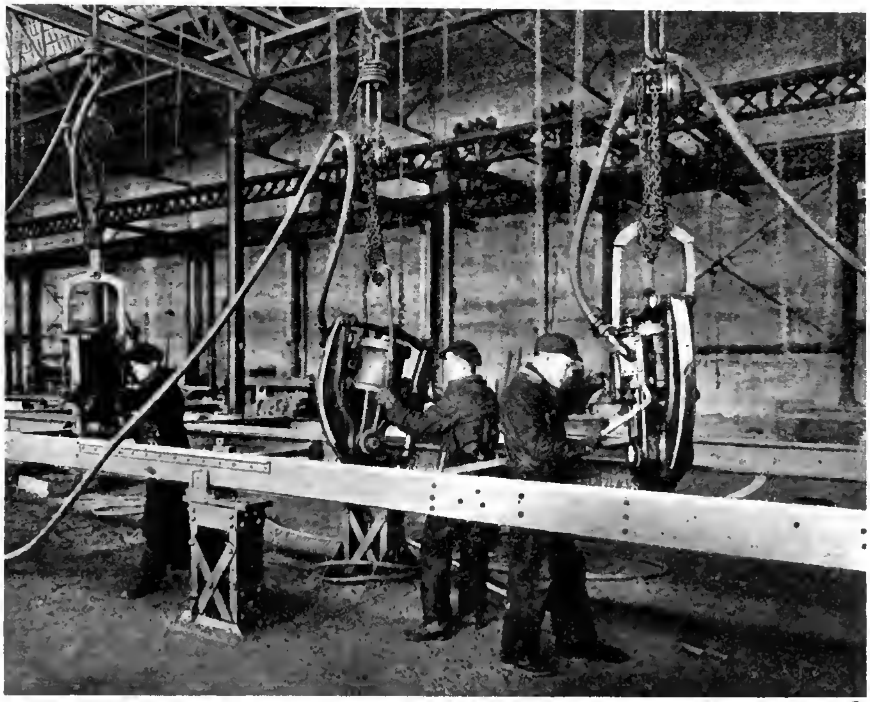
The paint shop to the north of the main four-span buildings is 1,100 ft. long by 150 ft. wide. It is not only used by the paint department, but also as a storage for cars, having accommodation for about 250 of the latter. In addition to the travelling cranes, each of the buildings has a system of narrow-gauge tracks, with turn-tables at intersections, thus giving a very flexible transportation service. Among the other accessory buildings which go to make up the plant are the following: Power house, dry kiln, lumber storage, general storeroom, paint and oil storage, locomotive house, general office, etc.

The Power House

The power plant, housed in a separate structure, is close to the west side of the main building, midway along its length, as central as possible without being too far from the supply of condensing water. The condensing water is taken from the East River, 1,000 ft. away. A pump house is built on the shore of this river, containing three electrically-driven pumps with remote control, so that the operator can start and stop them from the power house without the necessity of going to the pump house except for occasional inspection. Water for the boilers and for drinking, etc., is supplied free by the town of New Glasgow.

The power house building is 113 ft. by 120 ft., and is divided into separate engine and boiler rooms, with direct access to each. Three Edge-Moor type water-tube boilers of 600 horse-power each are installed; provision is also made for two more. All are equipped with Foster superheaters and Green chain grate stokers, and the installation is guaranteed for a continuous overload of 50 per cent. Overhead steel bunkers lined with concrete are provided for coal storage and a continuous conveyor handles the coal from the track hopper to the bins. Automatic ash conveyers are also installed. Provision has been made at each boiler for burning wood refuse and shavings, the material being handled by a blower system which delivers it direct to the boilers. Any boiler can in a few minutes be changed from coal to wood or vice versa, an arrangement which, it is found, gives better results than burning wood and coal together. The working pressure is 200 lbs. with 100 degs. superheat. The chimney which is of concrete rises 175 feet above the grates.

INTERIOR OF CAR WHEEL FOUNDRY SHOWING FLASKS.



PNEUMATIC RIVETERS AT WORK ON STEEL CAR FRAMES.

Engine Room

Both direct and alternating-current electric power is used. The alternating current is 3-phase at 600 volts and the

direct current, which is used on cranes and variable speed motors, is at 220 volts. The electric power plant consists of two 750-kw. turbines furnished by the Canadian General Electric Co. and there is provision for a third unit of the same size. One of the two turbines installed is equipped with a bleeder attachment which allows steam to be extracted between stages for heating or dry kiln purposes, the remainder of the exhaust going through the condenser. The other turbine is of the mixed pressure type, and can be run with either high or low pressure steam, or both. A motor-generator exciter set of 35 kw., and a turbine-driven exciter set of 25-kw. are also installed. During the summer months this machine can utilize the exhaust steam from the air compressors, hydraulic pumps and auxiliary machinery, making altogether a very flexible and highly economical combination arrangement.

BORING CAR WHEEL HUBS.

Auxiliary Lighting

A Terry turbo-generator of 125-kw. capacity has been installed to take care of overtime loads, such as night and Sunday lighting, etc. A 200-kw. motor generator set provides the direct current, with both steam driven and electric driven exciters. The switchboard and bus-bar arrangement has been designed particularly to make the plant highly flexible. The main circuits leave the power house in conduits and the whole system of electric connections in the power house is arranged with ample space to afford ready accessibility. The turbines are provided with synchronizing motors and are also controlled by a Tirrill regulator.

One cross-compound, two stage Canadian Ingersoll Rand, Corliss type air compressor of 3,000 cub. ft. capacity has been installed and provision made for a second unit of the same size. A hydraulic system has also been provided, one 3-cylinder compound, fly-wheel high pressure pump being now in service, while the second will be installed when opportunity offers. Two large accumulators are located in the power house to take care of load fluctuations.

Heating and Pumping

The main building is heated by four large fans and heaters provided by the Canadian Sirocco Co., these units each containing tiers of indirect radiation heated by exhaust steam from the power house. A Sirocco fan on each unit distributes the heated air through ducts to the various parts of the shop.

Beginning at the power house and extending across the entire width of the main building, a tunnel 6 ft. 6 in. by 7 ft., is provided with smaller branches leading to the various departments. In this tunnel are placed all main electric cables, steam, exhaust, air, and hydraulic piping, making it all readily accessible for inspection and maintenance.

Other power plant equipment consists of two Weir boiler feed pumps; Blake-Knowles feed water heater, Martin pump for taking care of heating system returns, Laidlaw-Dunn-Gordon hydraulic pressure pumps, two H. R. Worthington condensers of 1,600 and 3,100 sq. ft. of surface respectively, Blake-Knowles air pump, and Terry turbine driven centrifugal pump.

Foundry Department

The foundry department consists of two buildings, one housing the wheel foundry and the other the steel and gray iron foundry, with floor areas of 60,000 and 30,000 square feet respectively.

The wheel foundry is of the straight floor type, and is provided with pneumatic and electric equipment for handling all ladles, flasks and finished wheels. It is arranged for an ultimate capacity of four hundred wheels per day. Wheels can be rolled direct to the truck shop, a distance of 60 feet.

Export Trade

Three more hydraulic presses have recently been installed, the plant being now thoroughly equipped for the manufacture of "All-Steel" cars, in addition to all varieties of freight cars, cabooses and mine cars. At the present time it is engaged in filling an order for "All-Steel" coal cars of 100,000 lbs. capacity for the Canadian Government Railways, has just completed two thousand 75-ton cars for the Russian Imperial Government, and is working on 3,000 Standard cars for the French Government.

During the past two years the management has devoted a great deal of attention to the foreign market, and the

HYDRAULIC WHEEL PRESS FOR PRESSING ON WHEELS TO AXLES.

successful manner in which it has handled the large European orders already secured is a good indication of the position the company is in to take care of future orders from abroad.

In addition to the very large and complete equipment described and illustrated in these pages, the Nova Scotia Steel & Coal Co. fleet of ocean steamers for freight carrying purposes, is at the disposal of the Eastern Car Co. for taking care of their shipments of cars, car parts and equipment to European and other foreign markets.

The company has developed a system of manufacturing capable of producing forty cars daily. All types of freight cars, of wood or steel, are being constructed both for the Canadian and for the foreign market. The first order received when the plant started in 1913 was for 2,000 standard box cars for the Grand Trunk Railway System.

Russian and French Cars

During the early part of 1915 the Russian Government Railways and the French Government were in the market for a large number of cars. After demonstrating the ability of the Eastern Car Co. to deliver cars by their own steamers to any ports, the first order was secured from the Russian Government for 2,000 forty-ton steel frame box cars.

This type of Russian car is exceptionally large, and in a number of ways resembles the Canadian Pacific type of box cars. It is unusually long—43 feet, and has a carrying capacity of 40 tons of grain. The gauge of track for these cars is 5 feet, which is 3½ inches wider than the standard gauge of Canadian roads. The wheels are of cast iron—41⅜ inches in diameter. The roof is made of a design generally used in Russia, consisting of sheet steel on pine boards. There are no holes whatever through the sheets or the lap of the roof, therefore no danger of leakage. The running boards are protected by a railing, thus safeguarding the trainmen, who are not in the habit of walking along the roof of the small two-axle cars common in Russia. In these and other respects the Russian cars are designed specially to meet the requirements of the Russian State Railways.

When the French Government came in the market for a special type of freight cars, they placed with the Eastern Car Co. an order for 1,000 twenty-ton cars, and followed this later with an order for 2,000 more of the same type.

Both the Russian and the French Governments are, we understand, negotiating for further orders for freight cars, and from what we have seen the company is in an exceptionally good position to take care of these and other foreign car orders, in the order in which they are received.

LOADING FREIGHT CARS "KNOCK-DOWN" AT PICTOU LANDING FOR SHIPMENT TO RUSSIA.

Lumbering Department

The company controls, in its Newfoundland and Nova Scotia timber areas, 107 square miles of timber land, consisting of spruce, fir, hemlock, birch, beech and maple, from which the average yearly output of lumber is from five million to six million feet board measure. In Nova Scotia most of the lumber is sawn by portable mills which are taken into the district being lumbered, and the sawn lumber is hauled to the nearest railway siding. In Newfoundland, the logs are stream driven down the Gander River, and the sawmill is situated on an arm of Gander Bay, where steamers load for the Ore Mines at Wabana. Practically all of this lumber is used for the company's requirements, and at Wabana Mines, Newfoundland; Sydney Mines, C. B., and New Glasgow, N.S.

All the buildings except the main office are steel and concrete throughout. They are of a specially substantial type, and practically all material is stored under cover, there being no interruptions due to inclement weather. The principal lighting is done by flaming arc lamps, but in the power house and smaller buildings, large tungsten lamps are used. The main office which is located at the entrance to the plant is built of brick with stone and cement trimmings.

IMPORTANT TRADE COMMITTEES APPOINTED

THE President of the British Board of Trade has appointed two further committees to consider the position of certain branches of British trade after the war, with special reference to international competition, and to report what steps, if any, are necessary or desirable in order to safeguard that position. These committees are as follows:

Textile Industries

Henry Birchenough, C.M.G. (chairman), Sir F. Forbes Adam, C.I.E., James Beattie, T. Craig Brown, E. S. Fielder, J. W. Hill, Albert Illingworth, M.P., J. H. Kaye, E. H. Langdon, J. W. McConnol, H. Norman Roe, Sir Frederick Smith, Bart., T. C. Taylor, M.P., The Right Hon. Robert Thompson, M.P., Frank Warner.

T. Ainscough will act as secretary to the committee, and all communications relating to it should be addressed to him at 6 Whitehall Gardens, S.W.

Electrical Trades

The Hon. Sir Charles Parsons, K.C.S., F.R.S. (chairman), J. Annan Bryce, M.P., T. O. Callender, James Devonshire, B. M. Drake, Sir John Snell.

All communications should be addressed to the secretary, Electrical Trades Committee, at 7 Whitehall Gardens, S.W.

The president of the Board of Trade has further appointed Sir Joseph P. Maclay, Bart, and Summers Hunter, to be additional members of the Shipping and Shipbuilding Committee, and F. H. Marker, of the Board of Trade, to be secretary to that committee.

Steel Mill for Montevideo.—Uruguay is to have a mill to roll steel billets into merchant bars and small shapes. It is to be situated at Montevideo, and contracts are said to have been placed in Pittsburgh for an 18 in. train of rolls and other equipment. The project has been developed by A. Voulminot, formerly a representative of the American Bridge Co. in South America. The Government of Uruguay is to furnish half of the financial backing.

Russia's Machinery Market from a Competitive Viewpon*

By P. Gurewitch

As a potential purchaser, Russia possesses a peculiar fascination for producers in the leading industrial countries. That at some time in the future her large natural resources will alter the economic situation of the country, there is no doubt, but the probability of the nation's needs developing more rapidly than its production precludes the possibility of internal competition assuming monopolistic dimensions for several decades yet.

THE beginning of the machinery trade in Russia dates back to the early sixties following the emancipation of the peasants from serfdom in 1861, this far-reaching event giving the first impulse to Russia's conversion from a purely agricultural to a mixed agricultural and industrial state.

Early Stages

For many years thereafter the state was the most important customer, large quantities of railway materials, locomotives, etc., being required for the railways which were built by the state, whilst considerable orders were given for the army and navy. In view of the fact that early manufacturing enterprises were founded to supply the requirements of and were maintained by government work, the general market remained stagnant, and development was retarded by the absence of rivalry and competition such as existed in Western Europe. The result of this one-sided development was that in later years when an industrial crisis arose, due, among other causes to a lessening of railway orders, the country was dependent on foreign supplies for more than 40 per cent. of all machinery and apparatus not specially connected with railroad requirements.

Recent Growth

The extent and rate of development attained by Russia's machinery requirements can be gathered from the following table in which it should be noted that although its percentage of the total imports decreased slightly in 1913, the actual amount of machinery imports was increasing at a greater rate each year.

Years.	Machinery Imports to Russia. *Roubles.	Total imports of all goods to Russia. Roubles.	Machinery Imports in % of total imports. %
1911 ..	147,000,000	1,022,700,000	11.4
1912 ..	149,200,000	1,031,600,000	14.4
1913 ..	163,700,000	1,220,500,000	13.4

*Roughly 10 roubles (actually 9.46) go to the pound sterling. Thus the value in English money is given roughly by cutting off the last "0."

With regard to Russian home production of machinery, according to the statistics of the Russian Ministry of Finance in 1900, the whole of the state and private manufacturers produced various machines to the value of 52,000,000 roubles, on the making of which 49,000 workmen were engaged.

In the year 1908 the number of workmen increased to 110,000, and the values of machinery produced to 140,000,000 roubles. Thus the value of machines manufactured in Russia increased in eight years by 173 per cent., and the number of workmen by 124.5 per cent.

Value of Production

The value of machines produced in Russia in 1912 is calculated by expert authorities to be 210,000,000, which when added to that year's machinery imports gives a value to the year's demand of 360 million roubles (=say $180,000,000).

According to official statistics from the various authorities, this volume of machinery imports was divided amongst the four leading export nations as follows:—

	Exports of machinery to to Russia.	Total of machinery exports.	Exports to Russia in % of total exports. %
England	£3,885,664 = 36,758,000 R.	=£34,743,000	11.2
Germany	M.129,918,000 = 59,762,000 R.	M.678,000,000 =£33,450,000	19.2
Switzerland	11,741,000f. = 4,402,000 R.	76,776,000f. =£ 3,046,000	15.3
U.S.A.	....	$127,981,000 =£26,350,000	....
Total of machinery exports, £97,599,000.			

The figures show that Great Britain's share in the Russian market for machinery was the smallest, while nearly one-fifth of the total German and one-sixth of the total Swiss machinery exports went to Russia, only 11.2 per cent. of the whole of Great Britain's machinery trade was done with Russia. As the importer of 19.2 per cent. Russia was the chief importer of German machinery, as Germany exported to Austria in 1913 only 11 per cent. of its total machinery export, 10 per cent. to France, 7 per cent. to England, and 5 per cent. to Belgium, Holland, and Italy respectively. In five years the Germany machinery export to Russia increased more than $2\frac{1}{2}$ times, or 250 per cent., so that in 1913 it was $12,000,000, or 64 per cent. higher than the British export to the same country.

Skilled Labor Scarce

A scarcity of good engineers is felt everywhere, on account of there being insufficient middle and high grade technical schools. Only a few hundreds of young men can be taken yearly at each of the technical universities of Russia, while the number seeking admission to further their studies amounts to thousands. Hence the most severe entrance examinations have to be passed in order to lessen the number of the candidates. To this must be added, that special limitations are framed against Russian subjects who do not belong to the orthodox church, especially Jews, disqualifying them for entrance to the universities. The result was that thousands of young men used to go to Germany before the war to study at the technical schools. These young people, after having learnt the German language and gained a knowledge of Germany machinery and materials, after they returned to Russia and became managers of factories naturally gave German products the preference.

The lack of capital and long credit greatly checked the development of the Russian machinery industry. The establishment of companies was made difficult by the founders having to apply to the Russian Government for concessions, the statutes having to be laid before the Cabinet by the Minister of the Board of Trade for the purpose of ratification. The minimum capital required for founding a company as well as the value of shares, are, according to present Russian company law, much higher than in other countries. In the last years before the war the reactionary party limited, by its oppressive policy, the rights of the unorthodox citizens as regarded the founding of companies, thereby checking the progress of company promotion. The suspension of this harmful mediaeval religious persecution has been agitated for by most Russian industrial organizations and far-seeing politicians, but, to the great prejudice of the whole of Russia, in vain.

These are only a few of the chief reasons stigmatized by the most important Russian economists, far-seeing politicians, the corporations, trade societies and congresses, as the cause of Russia's weak development in industry.

*An abstract from a series of articles in The Engineer, dealing with British Machinery and the Russian Market.

This question has been gone into at length, in order to show that the hindrances to Russia's industrial development are of a passing character only, and that hand-in-hand with political progress and reform these evils will disappear. The war has brought out vividly the crying need for reforms, and it is to be hoped that they will soon be introduced. Then the Russian industry will develop by leaps and bounds, as there is an enormous inland market and no scarcity of raw materials.

Future Conditions and Influences

Then the Russian market will become of great importance to the English machinery industry, as the Russian industries being freed from the checking influences above mentioned will require enormous quantities of new machines of all kinds. The Russian machinery industry will be fully engaged in order to cope with the increased demands in simple machines for many years to come. Complicated and special machines will have to be imported for a long period from those countries which have a long experience in machine construction and do not work solely for a limited inland market, but for the world's markets. A machine manufacturer can only alter and perfect his models and produce a series of cheaper machines if he has an enormous output.

Having now dealt shortly with the future of the Russian machine industry, the present conditions will be reviewed.

Present Costs Handicap

The greatest obstacle checking the Russian machinery industry consists, however, in the enormous cost of raw materials, semi-finished products and fuel. This burden of costs has been a real calamity for the whole Russian industry for many years. The reasons of these unnatural high prices, which are unknown in other countries, will be discussed later.

In consequences of the extraordinarily high costs of production, the cost price per ton of even simple machines, according to the information of the Society of Manufacturers for the Moscow District, is in Russia £28.8 sterling dearer than in Germany. One-half of these increased productive costs is to be ascribed to the high prices of raw materials and fuel. The difference between the manufacturing costs of complicated machines is still larger.

The above explanations give the reason why even simple agricultural machines and implements are imported into Russia in such great quantities year by year.

Agricultural Machines

Russia being for the most part an agricultural country, its requirements for agricultural machinery are very large, but the Russian factories are not able to supply the country's requirements. However, it may be here mentioned that of all the branches of the Russian machinery industry the manufacture of agricultural machines is the most developed.

The inland production of machinery of this kind in Russia reached in 1911 a value of 48,000,000 roubles, in 1912 it increased to about 52,500,000 roubles, and shortly before the war it amounted to between 60 and 70 million roubles. The demand was, however, so large that agricultural machinery in 1911 to the value of 54,400,000, in 1912 of 58,700,000, and in 1913 of 63,500,000 roubles had to be imported from abroad. The total yearly requirements of the Russian market for agricultural machines were in 1913 about 125 million roubles (=$62,500,000).

The future prospects for this trade with Russia are excellent. Agricultural machinery to the value of $17,500,000 has not been able to enter Russia in consequence of the interruption of the last year's imports by the war. The Russian inland production of these machines has also greatly decreased. Apart from the stoppage in production of agricultural machinery in fifty-seven factories of Russian Poland, most other factories of inner Russia have had either to stop work altogether, or greatly to diminish their output, on account of lack of raw materials and fuel. In consequence of this one may assume that the importing of agricultural machines to Russia in the future will be even more considerable than in normal years before the war.

Prime Movers

While no specific figures can be given regarding English exports of prime movers to Russia, it is interesting to know that for internal combustion engines alone, the demand increased from $9,000,000 in 1910 to $13,000,000 in 1912, only one-half of the demand being met by the home makers. According to Professor Sawwin, the Russian industry in the last-mentioned year required steam engines, steam turbines, and portable engines to the value of $5,000,000, one-third only of the steam engine demand being met by inland production. The total value of Russia's requirements in prime movers increased from $16,750,000 in 1910 to $22,500,000 in 1912 in which year the total home production amounted to $7,250,000.

The German proportion of this business was very great, being 76 per cent., according to Russian statistics, but really amounting to less because of certain methods of classification. These exports, however, included 1,776 internal combustion engines, 808 portable engines, 264 steam engines, 77 water-power machines, and 57 steam turbines, amounting to 24 per cent. of Germany's total export of this class of goods.

Metal-Working Machines

In four years the total imports of these goods increased nearly three-fold amounting in 1913 to $6,350,000. The inland manufacture of metal-working machines in Russia is of all branches the least developed, very few factories producing such machines. In some quarters there is considerable agitation for a re-adjustment of the tariff, but the real causes of the weak development of Russia's production of metal-working machines are to be found in quite other direction which have already been dwelt upon. It is interesting to know that of the total British foreign trade in sewing machines in 1913, 35.5 per cent. value over $4,000,000 was sent to Russia, being nearly double that of Germany, and 3½ times that of the United States.

Mining Machinery

The chief provider of mining machinery was Germany, all large German manufacturing companies having their representatives in South Russian coal and iron districts, where however, the mines are chiefly in the hands of French and Belgian companies, who whenever possible, gave preference to machines of their own nationality. Owing to difficulties in the way of classification no statistics are available for comparison between different countries, but future prospects for this trade with Russia are excellent. After the war Russia's coal and ore production will be considerably increased, as all easily available supplies were used up long ago. Moreover, the imports from abroad, which were very considerable during the last few years, will hardly reach their former proportions in the period immediately following the conclusion of peace. Consequently Russia will be forced to pay increased attention to its own coal and ore production.

Conclusions

Coke, naphtha, iron, and copper production are all important industries which in course of time will assume their places of importance in the economic structure of the country, but not being finished products do not occupy the attention of manufacturers to the same extent as machinery, etc. Amongst the latter might be mentioned flour mill machinery, clay, lime and cement machinery, and machines for the wood and timber industry.

The question of Russia's present and future tariff policy is of vital interest to and affects the British machinery industry in no small degree. British machinery exports to Russia before the war amounted to 11 per cent. of Britain's total machinery exports, and it greatly depends on Russia's future tariff policy whether these important exports worth about twenty million dollars are promoted or checked.

Vol. XV. MAY 25, 1916 No. 21

THE ENTERPRISE OF "SCOTIA"

IN this issue considerable space has been given to a description of the various plants of the Nova Scotia Steel & Coal Co., as also to its subsidiary, the Eastern Car Co. Doubtless what will most strike readers of the different articles is the practically self-contained nature of the main and parent enterprise. Resources, location and ultra-created facilities as regards raw material entering into almost every class and type of wood and metal product, and the ease with which these can be made available or brought, so to speak, to the door of the consumer, lead one to the not unreasonable conclusion that such a concern could not do otherwise than make good, irrespective of occupying a foremost place in the industrial life of the country to which it belongs.

It will be abundantly evident, however, that something more than resources, location, and ultra-created facilities have brought this big Canadian corporation to its to-day-place of prominence in a world sense. The grim determination of the human element has permeated the career of the organization for a generation or more, and with it has been coupled an intensive and well-directed energy, safeguarded at every turning by native caution and the vision to anticipate and take advantage of opportunity. In view of the foregoing, small wonder is it then, that, the announcement of establishing a shipbuilding plant in connection with its other activities at New Glasgow and elsewhere has aroused not only the keenest interest in business and commercial circles, but has earned as well the enthusiastic commendation of Canada's citizens generally, and that of the shipping and shipbuilding fraternity particularly.

New life as it were, has been given to the shipbuilding industry throughout the Dominion, and in saying so we refer to the construction of steel steamships. In recent years many and varied attempts have been made to enthuse our Governments at Ottawa on the subject of support for Canada's shipbuilding enterprises, but somehow, and very probably on account of the lack of backing by our big steel corporations and others, a more or less deaf ear was turned to the requests and pleadings. Irrespective, however, of past experiences, and because of a new set of circumstances prevailing as a result of the war, there has developed a new attitude to the shipbuilding industry by our commercial and industrial interests, large and small. In consequence, we find the Nova Scotia Steel & Coal Co. now engaged in the preliminaries attendant on the creation of a steel shipbuilding plant with a view to construction of their first vessel.

Nova Scotia in years gone by occupied a place of no mean order in the shipbuilding of the world, but had to forego the distinction when steel vessels began to supplant those of wood for long or short deep sea services. Most sanguine expectations as to the outcome of "Scotia's" new venture find ready expression, and if one might judge by the results achieved by "Scotia" in its other spheres, there is little doubt but that the success predicted will be fully realized. It may be, in addition, that the province of Nova Scotia will again attain to its former high place in world shipbuilding, thereby reviving its former glory and adding lustre to it because of a dual significance.

WINTER NAVIGATION ON THE ST. LAWRENCE

IN connection with the launch of the ice-breaker, J. D. Hazen, from the plant of Canadian Vickers at Montreal recently, the possibilities of prolonging the winter service on the St. Lawrence River have been widely discussed. The opinion has been expressed that there was not a day during the whole of last winter when an ocean steamer could not have entered or departed from the port of Quebec, assisted perhaps during the most severe weather by such an ice-breaker as the J. D. Hazen.

The possibilities of the development of Canada's great inland ocean ports through a winter service on the St. Lawrence have long been considered in relation to Montreal and Quebec. Montreal as an all-year-round port would logically be the greatest shipping point on the continent. Situated at the heart of North America, it would be the great economic distributing point of both Canada and the United States. Such development of the port as has been effected has been in the face of the handicap of maintaining the overhead expense of facilities which can only be made use of during a portion of the year. The difficulties of the St. Lawrence route are many; there are delays from fog, slow navigation of the river channel, and loss of time, to weigh against the shorter mileage as compared with American ports—these in addition to the winter freeze-up. However, if, with the aid of ice-breakers, the route could be kept open to Quebec during the winter, it would benefit Canadian commerce and undoubtedly bring a measure of shipping revival to the Ancient City.

SHIP PLATES AND SHAPES PRODUCTION

A POINT worth noting in connection with the proposed subsidizing of shipbuilding in Canada is our ability to have the industry self-contained in so far as the principal materials—raw and finished—are concerned. Among the more important of the latter may be mentioned the ship's hull, tank, bulkhead and deck plating; frames, deck beams, etc. Plates for our ship, tank, and boiler construction are for the most part imported from the United States, and naturally, with a stimulation of either or both industries, imports of these commodities would correspondingly increase. The establishment of a plate mill in Canada capable of dealing with the requirements of at least medium-sized vessels would, therefore, seem to be in order, and is doubtless receiving attention in the proper quarters.

It has, however, always been our understanding that a whole plate mill equipment, although not installed, and capable of rolling steel plates up to 1¼ inches thick by 10 ft. wide, is available at one of our leading steel plants, and, doubtless, if the subsidizing of shipbuilding on our lake and ocean shores is determined upon and put into effect, the above-mentioned mill will be pressed into service.

INDUSTRIAL NOTABILITIES

DONALD HUGH McDOUGALL, general manager, Dominion Steel Corporation, Sydney, N.S., Director Nova Scotia Construction Co., is a native of Nova Scotia, being born at Cape Breton, September, 1879, son of John and Alexis McDougall. His education was received at the Government Mining School, Glace Bay, N.S., International Correspondence Schools and Dalhousie College Summer Schools (Mining Course), after which he occupied the positions of: Apprentice Mechanic, Assistant

DONALD HUGH McDOUGALL.
General Manager, Dominion Steel Corporation.

Mine and Railway Surveyor, Mine Surveyor, Civil Engineer, Engineer in charge of Construction, Dominion Iron & Steel Co., 1900; Assistant Resident Engineer, New York Central and Hudson River R.R., 1902; Manager, Wabana Mines, Nfld., 1904; Superintendent Mines and Quarries, Dominion Iron & Steel Co., 1907; Assistant General Manager Dominion Coal Co.; Superintendent of Mines and Quarries, Dominion Iron & Steel Co., and Assistant General Manager Sydney & Louisburg R.R., 1910; present position since January, 1916.

Mr. McDougall's new position carries with it the responsibility of directing the energies of 16,000 employees, and controlling the activities of what ranks among the largest single enterprises in Canada.

He is president of the Mining Society of Nova Scotia, a vice-president of the Canadian Mining Institute, a member of the Institution of Mining Engineers (England), and a member of the Canadian Society of Civil Engineers.

Mr. McDougall married Clara E. Gillis, daughter of John Gillis, in 1906, and resides at King's Road, Sydney, N.S., his family consisting of four sons and one daughter.

His clubs are: Royal Cape Breton Yacht; Halifax City; St. John's (Nfld.).

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., May 20, 1916—No new developments have transpired in the industrial situation during the past week. The effect of the enormous business resulting from war conditions, has been to steadily improve the general domestic situation, and the outlook for the future is encouraging. Increased interest is being shown in the development of foreign trade, and steps are now under way which will strengthen the mutual feeling already existing between the industrial forces of this country and those of our allies.

Pig Iron

The situation is unchanged, but owing to the strikes now prevailing in various sections of the States, the consumption of foundry iron has been materially reduced and prices have declined. Pittsburgh is quoting 30 cents lower on No. 2 foundry.

Steel

While the steel situation is comparatively unchanged, the general conditions show an easier tone, as the demand on future positions appears to be diminishing. Price quotations are holding firm, and in view of the fact that daily advances are no longer the rule, the conditions may be said to be improving.

While the demand for open-hearth steel is relatively as great as ever, unexpected offerings have materially reduced the tension under which the market has been laboring for nearly a year. This development has resulted in a decline of $5 a ton on billets and sheet bars, Pittsburg; a similar decline is noted in forging billets.

No price changes are noted this week in sheet quotations. Conditions in cold rolled strip are stronger and higher prices are apparently pending. The wire market is firm and steady and the demand is good with the exception of barbed wire which has shown signs of easing up. Makers of boiler tubes are well filled for this year's business especially on seamless tubing, which in some cases is booked into 1917.

Metals

Copper has taken on a little strength and the demand continues good. Tin is quiet at present, but consumption is still heavy and prices are firm. The spelter situation has started on a slide which at the present time, is difficult to define. Lead continues quiet, but remains firm. Antimony is declining every day and the supply is increasing.

Copper—Increased interest on the part of consumers and further export inquiries have added strength to the market, but no hevay buying has as yet developed.

London cables report a strong market on advancing prices, and quotations on standard spot has advanced £2 during the week; futures show an increase of £6 while spot electro is quoted £4 higher. This week's prices are £143; £141 and £158 respectively.

New York quotes 29½ for prime lake; 30 for electro and 27½ for castings; these prices being an advance of ½ cent lake and a decline of ½ cent on castings and electrolytic.

Local dealers report a fair market with conditions unchanged. Prices are firm at 33 cents for lake, 32½ for electrolytic and 31 for castings.

Tin.—While the present market is dull and quiet, consumption continues very heavy, the tin plate producers being exceptionally busy in meeting the demand for tin plates both for home and foreign marktes.

The London market is quiet and prices are easier;a decline of 15 shillings on spot and 5 shillings on futures, leaves the quotaion this week at £197-5 shillings and £197-10 shillings respectively. New York reports an advance of ¼ cent on a quotation of 49½ cents per pound.

Dealers here are quoting last week's prices on a quiet market, 49 cents per pound.

Spelter.—The decline in spelter continues and the question now before the market appears to be the extent of the present slump. Recent reports that the production of spelter was exceeding the

demand have resulted in the gradual decline, and consumers cannot be induced to buy while daily reports show a weakening market. Producers are busy at present, but unfilled orders are on the decrease.

London markets are very quiet on sharp declines, spot having fallen off £4 during the week and future £7 off; quotations now being £95 and £85 respectively. New York reports show a decline of 1⅜ cents per pound, being quoted at 15.425 per pound.

Local conditions are similarly affected and the market is exceptionally quiet on declining prices. A decline of 1 cent leaves this week's quotation at 19½ cents per pound.

Lead.—The situation at present is quiet and in the face of a weaker market in London, early future foreign business will be curtailed. Reports of considerable new business, however, have kept the market here fairly firm and prices are stationary.

Lead in London has shown a decline on the week of £2 12 shillings, spot being quoted at £31 12½ shillings with futures 5 shillings easier. This weakness however has not yet affected the American market, New York still quoting 7½ cents per pound.

Prices here are unchanged but with an easier tone, this week's quotation being 9¼ cents per pound.

Antimony—This market is quiet and still on the decline. Consumers are showing little interest in the situation and further declines are not unlikely. New York reports a decline on the week of 5 cents, the present price being 30 cents per pound. Following the action of foreign interests local dealers have also declined on antimony, this week's quotation of 41 cents showing a drop of 3 cents per pound.

Aluminum.—The situation is unchanged with prices firm at 68 cents per pound.

Machine Tools and Supplies

The principal purchasing at present is on small orders for single machines. The eagerness of buyers is not so pronounced as a few months back, and the demand for machinery of the special purpose type is now being replaced by inquiries for standard machines. The situation as regards supplies shows no change, high prices and limited supply still prevailing.

Old Materials

Dealings in scrap metals appear quite active, but quoted prices in many instances are being shaded. Activity in scrap zinc is falling off. Aluminum scrap is active following a period of dullness. A decline of ¼ cent is noted in tea lead and scrap zinc is ½ cent lower. Other metals and material are comparatively active with quotations firm.

Toronto, Ont., May 23.—Trade continues active all over the country and a better feeling prevails in business circles generally. Annual reports of the many companies issued nearly all bear witness to the wave of prosperity that is passing over the Dominion, some of these concerns being only as a matter of fact indirectly benefited by war orders. The fact that these conditions will end sooner or later is being more fully appreciated by manufacturers who are becoming more united in their efforts to develop markets outside Canada. The possibilities of development in the export trade during abnormal times has already been proven and the opportunities of opening up new markets have never been more favorable. Some concerns are doing a big export business as a result of individual effort, while other organizations have also been most successful in securing business from various parts of the world. The experienced gained now should help considerably in retaining a hold in those markets after the war when conditions become more normal. The Canadian Commission which will meet in London, England, early in June is another step towards the development of export trade. The closer commercial union between the Empire and our Allies will be a distinct advantage to Canada and will be productive of wider markets and consequently a large volume of trade.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

There is no improvement in the situation as regards shortage of labour and raw material. The problem will become difficult to solve as time passes there being no prospect of any relief this year, at least. Enlistments are drawing men from the factories and production is being curtailed in consequence. The increasing demand for iron and steel is greater than the mills can take care of, the result is that these commodities cannot be obtained in sufficient quantities to cover the requirements of the manufacturers of finished products. In this case there appears to be little if any possibility of improvement in the situation during 1916, as the mills are already booked up for the fourth quarter, and in some cases well into 1817. Prices of all steel products are consequently high even if they do not advance much further they will in any case remain at a high level.

Steel Markets

The situation in the iron and steel market continues favorable. Quotations are steady but have still an upward tendency, although few price changes have been made during the week. The export demand is an insistent as ever and is keeping the market in a buoyant condition. The domestic demand is improving but is somewhat restricted owing to the delay in getting steel, deliveries being more backward than ever. The wrought iron pipe market is strong and prices firmly held with prospects of an advance in the near future; skelp is scarce and high in price. Boiler tubes are firm and deliveries are now running into the last quarter. Makers of shafting are practically sold up for the remainder of the year, and prices are very firm and unchanged. Plates have advanced 25c per 100 lbs. and are now quoted as follows: plates ¼ in. to ½ in., $4.25; heads, $4.50, and tank plates 3-16 in., $4.75 per 100 lbs.

The sheet market continues strong and prices will possibly advance. Inquiries for many weeks have embraced tonnage far beyond the capacity of the mills. The demand for blue annealed sheets is particularly heavy, while deliveries on black sheets are also very backward. The galvanized sheet market is unchanged and little hope is entertained by most makers for an early improvement. The spelter market is unsettled and the price is still too high to interest the galvanizers, for this reason many plants are operating at considerably reduced capacity.

The steel market in the United States is steadier than it has been for many months and may have reached the top point. It is thought however that it will be several months before prices begin to decline as the demand for steel is still very great, and is likely to remain so for a considerable time. There appears to be little danger of any marked weakness developing in the market, even after the war, as there will be a big demand for steel in Europe during the period of reconstruction, and the mills in the States and also in Canada will be called upon to furnish heavy tonnage of steel products. Prices are generally firm but unchanged this week. Steel bars are quoted at 3c, plates, 3.75c, and shapes 2.60c, f.o.b. Pittsburgh.

Pig Iron

The market continues firm and the situation generally is unchanged. The consumption of steel-making pig iron is as heavy as ever, while foundry grades are in better demand. Quotations are firm and unchanged.

Old Materials

The market is steady with a fair demand for scrap copper and heavy melting steel at unchanged prices. Both lead and zinc are weaker but quotations are practically the same as last week. The market has a better undertone and an improved demand is expected for some old materials.

Machine Tools

It is highly probable that the railways will be in the market at no distant date for new equipment for their car plants. A part of the government subsidies may be appropriated for this purpose, as the railways have been out of the market so long that new machine tools will be required. The large order for freight cars recently placed by the Dominion Government for the Intercolonial Railway will no doubt bring the car companies in the market for some equipment. Inquiries for single purpose lathes and other special tools for munition plants continue fair, but the backward deliveries on standard tools is tending to restrict the volume of business.

Supplies

A good demand for most lines of machine shop supplies is reported, and prices continue to have a higher tendency although there are no changes of particular importance to note this week. Putty advanced 15c and is now quoted at $3 per 100 lbs., in drums. Turpentine is steadier but the linseed oil market is still weak and unsettled. Oil is being quoted by some dealers at 89c-92c, but others are quoting 85-88c for raw and boiled oil respectively.

Metal Markets

There has been no development of any particular importance in the metal markets since the last report. Outside of a brisk demand for copper and continued strength in that market, the general tendency has been quiet, with the single exception of antimony which is lower; quotations are unchanged this week. Business locally is good, the demand for lead, copper and antimony being heavy.

Copper.—The market is quiet but the general situation has undergone no change and continues strong. There is reported to be a great shortage of copper in Europe which should result in heavy buying in the near future. Quotations are unchanged and nominal at 32c per pound.

Tin.—The market is steady and dull with quotations unchanged. The problem of getting licenses to ship tin from England is still an important factor in the situation but it is believed that permits will be granted with greater freedom in the future. Tin locally is nominal and unchanged at 54c per pound.

Spelter. — The market is dull and easy. Producers are said to have sufficient business booked to keep them busy for another month but their unfilled orders are steadily decreasing. Consumers are keeping out of the market although there is considerable buying in prospect. Spelter is weak and unchanged at 21c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

Lead.—The London market is weaker and New York dull and easy. The "Trust" price is unchanged at 7.50c, New York. Some large business is reported to be pending which will stiffen the market. Local quotations are unchanged at 9½c per pound.

Antimony.—The market is weak and lower. Consumers are showing no interest in the market. Antimony has declined 1c and is now quoted at 44c per pound.

Aluminum.—The market is quiet but firm and quotations are unchanged at 68c per pound.

TEXTILE MACHINERY

TEXTILE machinery, says a recent issue of the British Trade Review, is in request, and export orders are coming well to hand. Trade has improved greatly Difficulty is being met with in the fulfilment of orders by engineering firms owing to shortage of skilled labor and higher costs of raw material. One large Belfast firm with good Dundee connection has secured a considerable volume of new orders, and has booked contracts at remunerative prices. Foreign orders are also receiving attention, and shipments are being made abroad. The firm in question specializes in all kinds of machinery dealing with jute, flax, hemp, manila, and sisal.

Orders for bag-making machinery have been well in evidence—sack cutting, sewing, and printing, and for a time works had delay in executing the contracts for manufactories. Extensions of engineering establishments have taken place, and several are now in hand. There is a constant inquiry for new up-to-date plant, such as large modern carding machines for the jute and flax industries.

Orders from Calcutta are to hand, and consignments are sent out, chiefly spare parts and replacements, also looms to meet the demand for extension. An important order for a mill extension in Calcutta—engines, boilers, shafting, and machinery—was delayed, and building operations had to wait until the necessary plant could be sent out from Great Britain. Dyeing and cloth-finishing plant has also been booked in considerable volume, and extensions of these departments in factories have given occasion for good orders. The great improvement of trade has led to the installing of the newest type machinery to economize labor charges and augment output.

TO BUILD VESSELS IN B. C.

CONTRACTS were awarded on May 19, to the Wallace Shipyards of North Vancouver for the construction of three steel vessels, the hulls to cost about $400,000. Machinery, which will include large oil engines, will be additional. The boats are to be used in the lumber carrying trade from British Columbia ports, and are to be built under an interest guarantee of the British Columbia Government.

H. W. Brown is in charge of the contracts, and associated with him are H. M. Wolverin, a Great Lakes transportation man; James Carruthers, president of the Canada Steamship Lines; G. W. Norcross, of Montreal, vice-president and managing director of the Canada Steamship Lines; James Whalen, of the British Columbia Sulphite Co., and president of the Western Drydock & Shipbuilding Co., of Port Arthur; M. J. Haney, of Toronto, capitalist and contractor, and Sir Trevor Dawson, managing director of the famous Vickers Ltd., of Great Britain.

RISK OF TRANSSHIPMENT

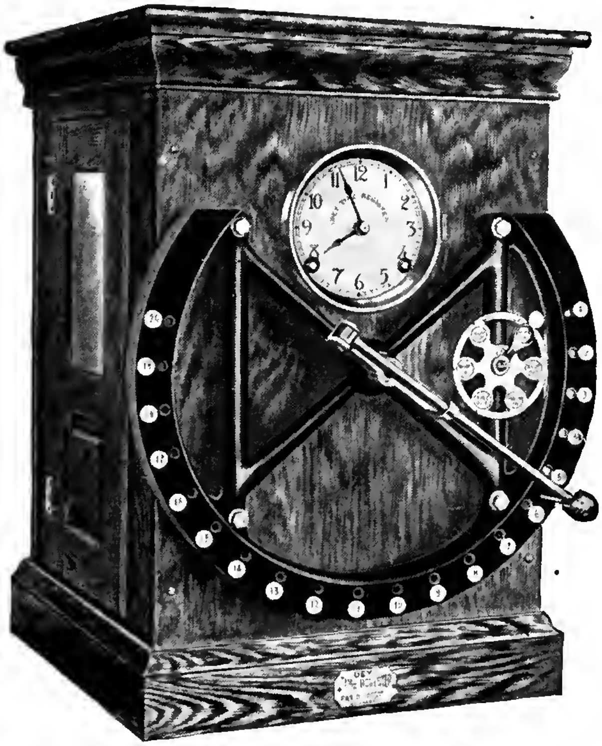
WHERE a shipment is made to a foreign port, with transshipment at an intervening port, the risk of transshipment is borne by the shipper and not by the carrier, except where gross negligence on the part of the carrier can be proven.

Here's the way to save a year's dividends

You have competitors? Yes! Look around and you'll see they use International Time Recorders. That's why they are SUCH competitors.

There's no argument about "working time" being the greatest of all raw materials you buy, yet many manufacturers permit four leaks a day in the supply every man on their pay-roll sells them.

"Walking time"—there's the biggest leak. The time the employees take *after* ringing in on the Recorder and *before* they get to work.



Check this loss. Put an International Time Recorder at the door of each department. Then it's up to the foreman to see that every man is busy at his bench or machine—and he'll do it.

Our big, new Canadian factory is prepared to make a Time Recording system to exactly suit any business—even yours.

Prices and new literature on request. Write to-day for it. No time like the present to start saving money.

SOUTH AMERICAN TRADE OPPORTUNITIES

THAT Canadian manufacturers may, if they seize the opportunity, gain a very valuable trade in South American countries which hitherto have received a very large proportion of their supplies of manufactured goods from Germany is the opinion of J. Enoch Thompson, Spanish Consul in Toronto. The field in the southern continent of America, he says, is simply waiting for the advances of salesmen from this and other countries. Germany has been cut off nearly altogether from South America, and in order to introduce Canadian-made goods into that territory the manufacturers of Canada must aim first to adapt themselves to the needs and demands of the people of the Central and South American countries, which are chiefly Spanish-speaking.

The annual imports of these South American peoples amount to 1,600 million dollars, and much of this huge volume of trade could be supplied from Canada. For example, Argentina, Brazil and Chili import annually the following articles:

Argentina

Agricultural machinery and tools	$10,000,000
Soap	600,000
Cheese	2,000,000
Leather goods	2,000,000
Paper	10,000,000
Pianos	1,300,000

Brazil

Wheat and flour	$20,000,000
Butter, cheese and provisions	7,000,000
Pianos	800,000
Ships	5,000,000
Sewing machines	1,500,000
3,338 pianos	1,000,000

Chili

Animals and animal products	$ 7,000,000
Agricultural implements	1,500,000
Paper	3,000,000
Cotton goods	11,000,000
Lumber and furniture	2,000,000

If our manufacturers and exporters wish to extend their trade to Spain and South America they have an opportunity now which may never again occur," declared Mr. Thompson. "To take advantage of it they must issue Spanish catalogues and correspond in that language, following it up by sending representatives who speak Spanish. Here is what a Venezuelan paper, El Fonografo said, six months ago, quoting a Mr. Serret, a Frenchman, who has lived many years in South America, who explains first the causes of the commercial preponderance acquired by Germans in South America. He affirmed that they owed it to their method, their power of adaptation and their lack of scruples, which distinguish them, as well as the paternal solicitude of the Imperial Government.

On the navigable waters of all the coasts, especially of the South Pacific, until August, 1914, were seen innumerable German vessels which, thanks to the generous subvention given by their Government, could cut freight rates much below standard rates and thus secure most of the important cargoes."

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

DON'T WASTE TIME PUZZLING OVER YOUR TAPPING PROPOSITION

Submit it to us, and our Experts will tell you how it can be done
TO YOUR BEST ADVANTAGE

Geometric Collapsing Taps are arranged for all classes of thread tapping above ¾-inch diameter. Rigid while tapping, but collapse the chasers when the required depth is reached. Can be fitted to screw machine or turret lathe, also to live spindle, such as a drill press.

Let us send our booklet describing these Geometric Collapsing Taps in a general way, or, with your specifications at hand, we will describe your Tap in particular.

The Geometric Tool Company

New Haven, Conn., U.S.A.

Canadian Agents: Williams & Wilson, Ltd., Montreal

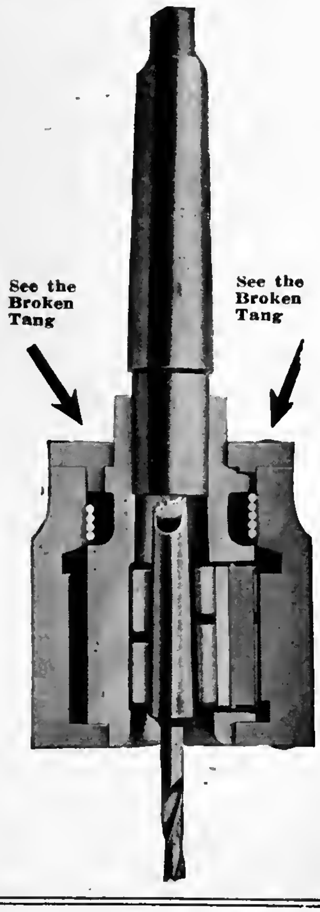
Geometric Collapsing Tap, Class "N-L," Equipped with Chasers for Plug Tapping



Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off —DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1¼"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops.

The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Hamilton, Ont.—M. Brennan & Sons are in the market for a nailing machine.

Watrous, Sask.—The Watrous Electric Light Co. will install a new gas producer plant.

Toronto, Ont.—J. T. Hepburn Co., are building an addition to their machine shop on Van Horne Ave.

Montreal, Que.—H. Morgan & Co., 16 Beaver Hall Hill, will build a brick and concrete garage to cost $10,000.

Niagara Falls, Ont.—The American Cyanamid Co. have started work on a plant to cost $20,000. H. P. Eastman is manager.

Ruscomb, Ont.—William Lockhart is considering the erection of a plant for the manufacture of brick, tile, etc., to cost $10,000.

Brantford, Ont.—The American Radiator Co. has been granted a permit for the erection of an addition to its plant, to cost $8,000.

Chatham, Ont.—After some delay in the delivery of steel for the plant of the Dominion Sugar Co., delivery of several carloads of material has begun.

Vancouver, B.C.—The City Council will install a 4-in. pump, including motor, at the Parker Street pumping station. F. L. Fellows is the engineer.

Penetang, Ont.—The Dominion Stove & Foundry Co. is making extensive additions to its plant, and will install equipment for the manufacture of furnaces, etc.

Vanvouver, B.C. — The Begg Motor Co. will have an addition built to its plant immediately at a cost of $15,000. The Dominion Construction Co. is the contractor.

Medicine Hat, Alta.—The Lake of the Woods Milling Co. will build a large steel and concrete mill to replace the one recently destroyed by fire with a loss of $200,000.

Cobalt, Ont.—The Trethewey Mining Co. is at the present time experimenting with the treatment of tailings from the mill dump. A small flotation plant may be installed if the experiments are successful.

St. John, N.B.—Work has started on the foundaton for the new foundry and machine shop for the T. McAvity & Sons, Grant and Horne of this city are the contractors for the new buildings which will cost over $100,000.

Port Arthur, Ont.—Fire recently damaged the pattern storage at the plant of the Western Dry Dock & Shipbuilding Co. The loss of the building is estimated at $25,000, but a large number of valuable patterns were destroyed.

Edmonton, Alta. — The Provincial Legislature has ratified an agreement between the Edmonton Power Co., care G. W. Farrell & Co., Montreal, Que., and the Edmonton City Council, for the supply of power for 21 years. The company will construct a power house, large dam, electric railway and other works at a cost of $6,000,000.

Galt, Ont.—The Goldie & McCulloch Co. are making extensive improvements to their south plant, and work has already been commenced by the contractors. Secord and Sons of Brantford. At the rear of the office a power house is being erected. Alterations to the office are also planned. The cost of the extensions as estimated at about $55,000.

Municipal

Chatham, Ont.—The City Council have decided to buy a motor truck for the fire department.

Stratford, Ont.—The local Hydro-Electric Commission contemplate installing three 750 k.w. transformers.

Ottawa, Ont. — The appointment of City Commissioner is under consideration at a salary of $6,000 per annum.

Gananoque, Ont.—The Town Council contemplate making extensions to the waterworks system.

St. John, N.B. — The City Council contemplate making considerable improvements and extensions to the water distribution system.

St. John, N.B.—The city council are considering the installation of a incinerator. The work will probably be proceeded with this year.

Brantford, Ont.—The city council have passed on to the ratepayers a by-law to issue debentures for $58,000 for hospital extensions, the vote to be taken June 26.

Estevan, Sask.—A by-law will be voted on by the ratepayers to raise $5,000 to pay for the completion of the electric power plant.

Point aux Trembles, Que.—The town council have under consideration a number of civic improvements, including the installation of a waterworks system.

New Glasgow, N.S.—The Town Council is considering the purchase of two new chemical wagons, one with engine, wagons and hose, and the other for ladders and hose.

Wyoming, Ont.—The village council decided at a special meeting held on May 13, to sell the present gasoline lighting system in the town hall and substitute the hydro-electric.

Yorkton, Sask.—The town council will proceed with the installation of a second 500 h.p. unit in the municipal power house without delay. The plant will then have a capacity of 1,150 h.p.

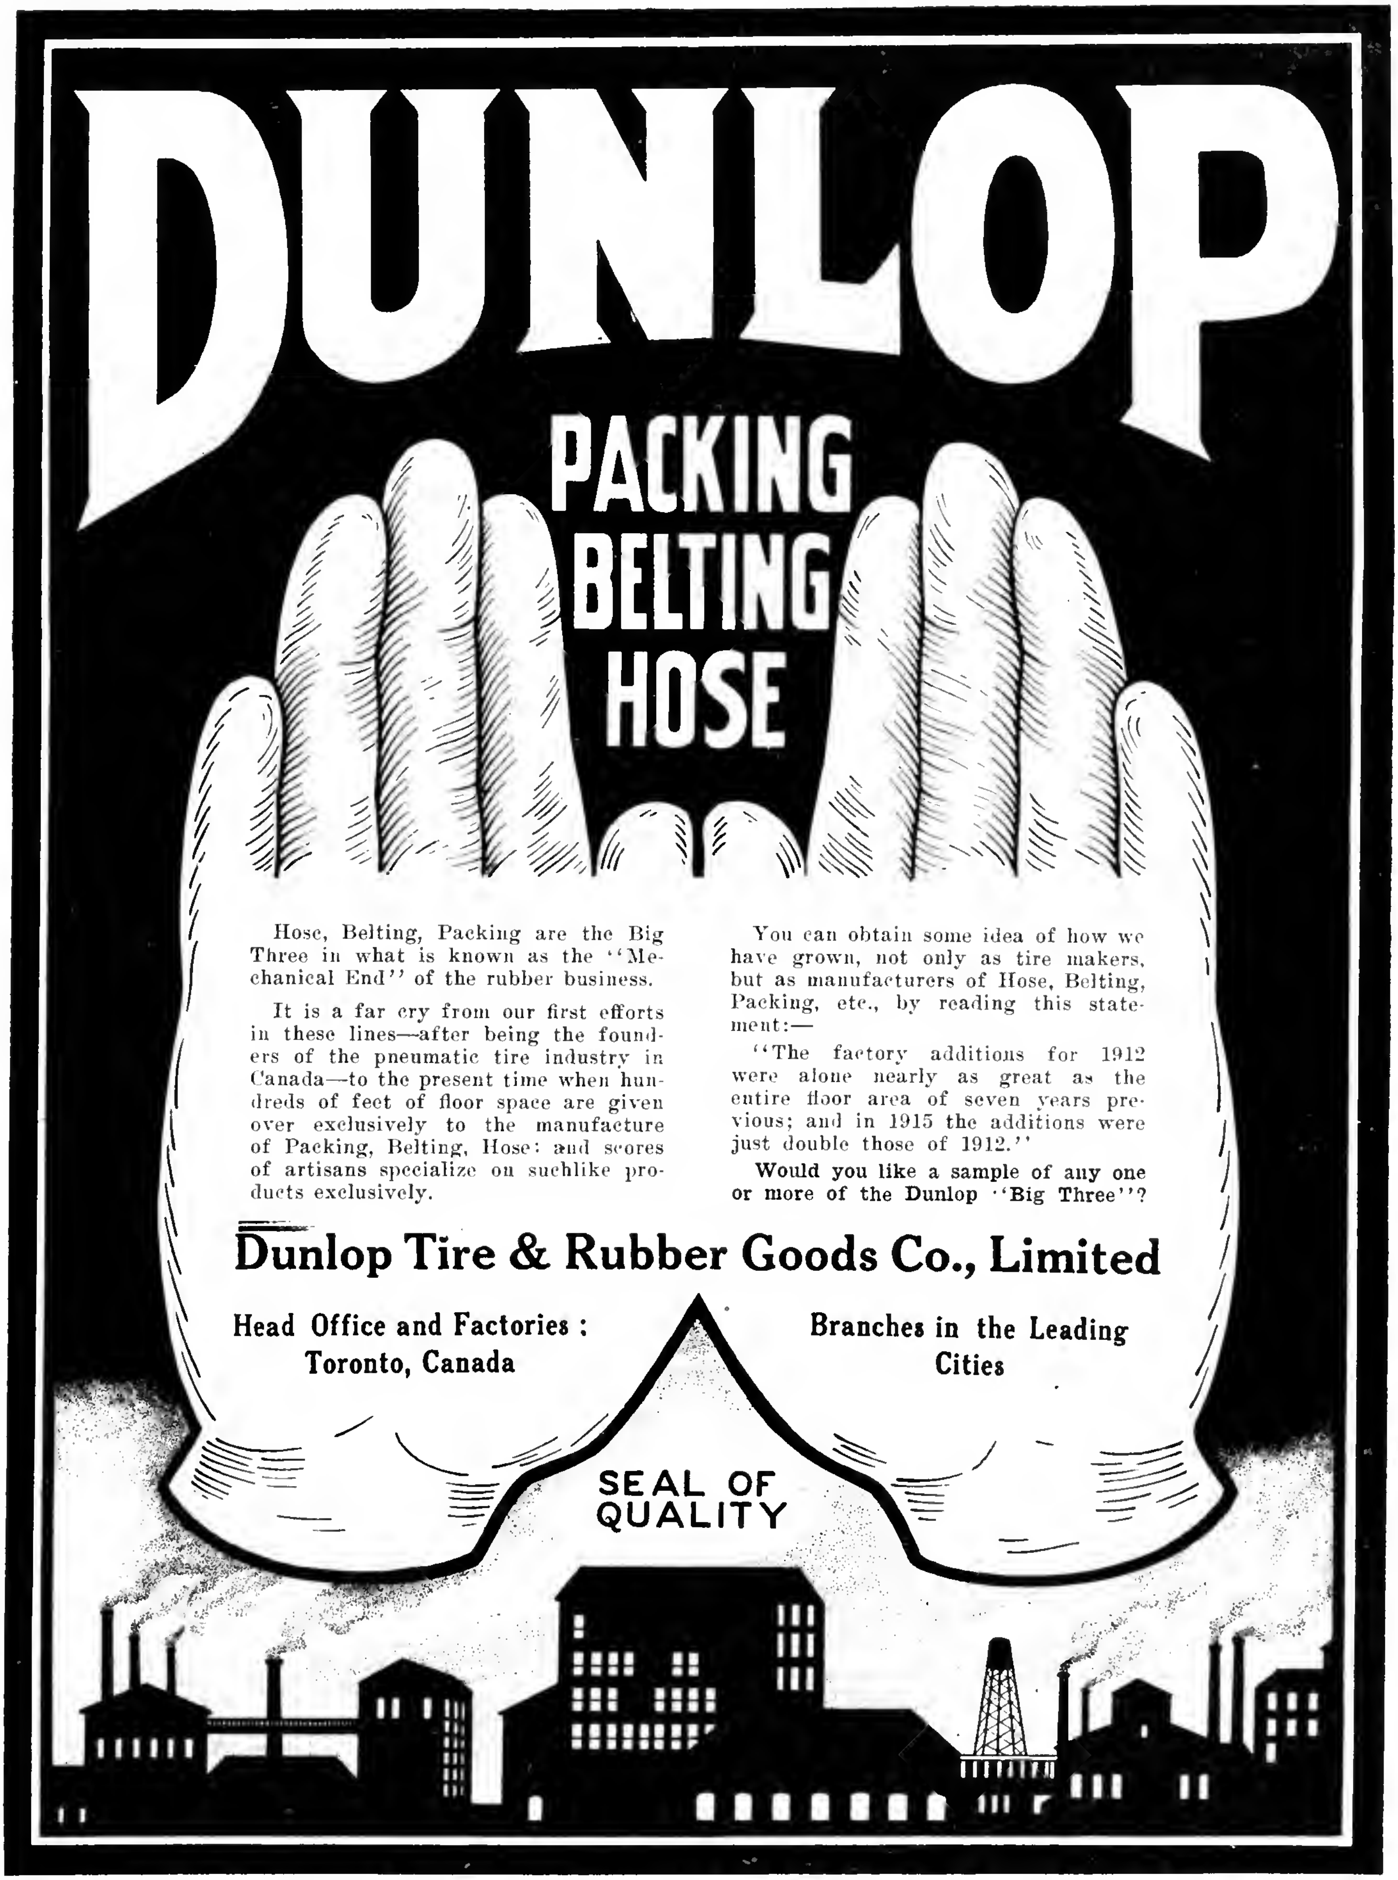
Loan to Paper Mills.—The by-law authorizing the loan by the town of Campbellford to the Northumberland Paper & Electric Co. of the sum of $30,000 to assist them in the rebuilding of their paper mills recently destroyed by fire, was carried by a very large majority on May 22.

Saskatoon, Sask.—The authority of the Local Government Board for the proposed expenditure on the incinerator and site, is likely to be delayed, as the chairman of the Board seems to be of the opinion that the Public Health Commissioner should be consulted in the matter.

Welland, Ont.—County Clerk Cooper has received notice from the Minister of Public Works that the country is authorized to spend up to $100,000 this year on good roads construction, and $12,000 for repairs. He advises, however, that construction be kept down to the lowest possible figure meantime.

Scarboro, Ont.—The Township Council has decided to erect a modern municipal building, which will house the various township offices and will also contain an ample council chamber. While no plans or specifications have been drawn as yet, it is stated that the proposed new structure will be one of the most up-to-date municipal buildings in the county and will cost over $5,000.

Orillia, Ont.—The by-law for transferring Orillia's power plant to the Ontario Hydro-Electric Commission, submitted to the ratepayers on May 22, was defeat-



DUNLOP
PACKING
BELTING
HOSE
Hose, Belting, Packing are the Big Three in what is known as the "Mechanical End" of the rubber business.
It is a far cry from our first efforts in these lines—after being the founders of the pneumatic tire industry in Canada—to the present time when hundreds of feet of floor space are given over exclusively to the manufacture of Packing, Belting, Hose: and scores of artisans specialize on suchlike products exclusively.
You can obtain some idea of how we have grown, not only as tire makers, but as manufacturers of Hose, Belting, Packing, etc., by reading this statement:—
"The factory additions for 1912 were alone nearly as great as the entire floor area of seven years previous; and in 1915 the additions were just double those of 1912."
Would you like a sample of any one or more of the Dunlop "Big Three"?
Dunlop Tire & Rubber Goods Co., Limited
Head Office and Factories: Toronto, Canada
Branches in the Leading Cities
SEAL OF QUALITY

ed by an overwhelming majority, the vote standing 513 against the by-law to 79 for it. Though it was admitted that the town would gain financially under the proposed arrangement, the townpeople were strongly opposed to giving up control of their generating plant, which has been in operation for nearly fifteen years. The town will now have to proceed with the completion of their new plant at the Swift Rapids, at an estimated cost of $90,000.

Tenders

Charlottetown, P.E.I.—Tenders are being called for an oil engine-driven pump for the waterworks plant. Tenders for a boiler may be called for within a few weeks. R. S. & W. S. Lea, of Montreal, are the consulting engineers, from whom particulars may be obtained.

Weyburn, Sask.—Tenders will be received up till June 1, addressed to the City Commissioners, Weyburn, for the supply and erection of one 500 k.w. steam turbine, generator, switchboard and auxiliaries.. All information may be had by applying as above.

Toronto, Ont.—Tenders will be received at the Department of Public highways of the Province of Ontario up to June 9, for the supplying of motor vehicle markers required for the year 1917. Specifications and forms for tender may be obtained from W. A. McLean, Deputy Minister of Highways.

Sarnia, Ont.—The Board of Education will receive tenders, until June 1, 1916, for the erection of an eleven-roomed school building. Plans and specifications may be seen at the Board of Trade Room, City Hall, Sarnia, or with the Architects, Messrs, S. F. Coon and Son, Ryrie Building, Yonge street, Toronto.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, up to June 6, for the supply and delivery of coal meters for measuring coal at Main and High Level Pumping Stations. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Winnipeg, Man.—Tenders will be received at the office of the Board of Control, up to June 5, for the supply of one combination gasoline pumping engine and hose wagon, with a pumping capacity of 700 gallons per minute, and capable of carrying 1,000 feet of 2½ inch fire hose. Form of tender may be obtained at the office of the chief of the fire department, Central Fire Station.

Ottawa, Ont.—Tenders will be received until May 31, for the construction of station, water tank, engine-house, transfer platform, standpipe pit ash-pit and turntable foundations for the Carleton Point Car Ferry Terminal, Prince Edward Island. Plans, specifications and form of contract may be seen at the office of the Chief Engineer, Department of Railways and Canals, Ottawa, the Chief Engineer, Canadian Government Railways, Moncton, N.B., and the Engineer in charge, Car Ferry Terminals, Carleton Point, P.E.I.

Wood-Working

Elmira, Ont.—The Elmira Planing Co. is building a new mill, to cost about $25,000.

St. Clothilde, Que.—A saw mill will be built here by the Bergeron Co. to cost about $5,000.

Simcoe, Ont.—The lumber and planing mill of Lewis Fick & Sons was destroyed by fire on May 11.

Montreal, Que.—S. W. Halliday, will build a carriage factory on St. Catharine Street, at a cost of $6,000.

Toronto, Ont.—The Ontario Show Case Co., West; Toronto is in the market for a wood-turning lathe.

St. Mary's, Ont. — The St. Mary's Wood Specialty Co., is in the market for a 16-in. buzz saw planer or joiner.

Building Notes

Toronto, Ont.—The McClary Manufacturing Co., will make addition to their warehouse at 177 King street West, at a cost of $3,000.

Toronto, Ont.—The Trusts & Guarantee Co. will erect an eight-storey office building on Bay Street, to cost about $50,000. Curry & Sparling, of Toronto, are the architects.

Toronto, Ont.—The City Council has decided to provide $30,000 for the Board of Education Administration Building, $38,000 for the High School of Commerce, and $284,395 for the Technical School.

Windsor, Ont.—By a majority of 346 votes the ratepayers sanctioned the expenditure of an additional $95,000 for the erection of a new Collegiate Institute building. The $100,000 which had previously been voted was not sufficient to cover the cost of the building.

Toronto, Ont.—A permit for the construction of the large mail order building on Mutual Street has been given to the Robert Simpson Co. by City Architect Pearce. The building, which will front on Mutual Street, will run back to Dalhousie Street, and will cost $400,000.

General Industrial

Toronto, Ont.—The Comfort Soap Co. will build an addition to the their factory to cost $4,000.

St. Catharines, Ont.—The McKinnon Dash Co. will build an extension to their factory here, to cost $70,000.

Port Hope, Ont. — A syndicate has taken over the old plant of the International Tool Steel Co., S. E. Brandon is interested.

Toronto, Ont.—The Flint Varnish & Color Works, Perth avenue, will erect a one storey brick and concrete factory, at a cost of $12,000.

Listowel, Ont.—The Canadian Mill Products Co., of Brownsville, Ont., will probably build a factory here at an approximate cost of $100,000.

Toronto, Ont.—Thompson-James Co., 43 Davies avenue, will build a one-storey brick factory at the east side of Broadview avenue near Wilton avenue, at a cost of $3,800.

Toronto, Ont.—The Wm. Neilson Co. will build an addition to their ice cream and candy factory at a cost of about $25,000. Sproat & Rolph, of Toronto, are the architects.

Montreal, Que.—Damage estimated at $30,000 was done by fire in the establishment of Louis Winstainer & Son, manufacturers of picture frames, 58 St. Lawrence Boulevard, on May 20.

St. Catharines, Ont.—The Dominion Food Co. have started work on the construction of a jam factory to cost $20,000. T. H. Wiley of St. Catharines is the architect.

Chatham, Ont.—At a special meeting of the City Council held on May 17, it was decided to grant to the American Pad and Textile Co., a strip of boulevard on Jeffrey street, ten feet wide at the rear of the plant. The company is planning the erection of a large addition at a cost of over $30,000.

Elmira, Ont.—A by-law authorizing a loan of $15,000 to the Colonial Knitting Co., has been carried by a majority of 264. The Knitting Co. comes from Guelph and will put up a large building. Machinery worth $25,000 is to be installed. The by-law to grant exemption of general taxes for 10 years to the Elmira Planing Mills Co., passed with 218 votes in favor and 60 against. A plant, 70 feet by 90 feet, all of concrete, will be erected.

Electrical

Stratford, Ont. — The local Hydro-Electric Commission has decided to install three transformers at a cost of $35,000.

Welland, Ont.—The Municipal Hydro-Electric Commission have asked the City Council for $12,000 to cover the cost of further extensions to the street lighting system.

Orillia, Ont.—The Hydro Electric Commission propose taking over the development at Swift Rapids. The Commission has offered the Town of Orillia $225,000 exclusive of transmission lines.

Orangeville, Ont.—Town Council has made the Cataract Electric Co. an offer of $7,000 for its distribution system in that town. Work on the hydro at that place is expected to commence at once.

Personal

George McKnight has been appointed city engineer of Fredericton, N.B.

R. M. Hannaford, assistant chief engineer of the Montreal Tramways Co., has been elected president of the Canadian Railway Club, Montreal.

Sir George Foster, Minister of Trade and Commerce, will leave for England probably this week and will be over there for some time.

J. E. Macfarlane has assumed the duties of general manager of the Western Canada Flour Mills Co. with headquarters at Winnipeg.

Thomas Roden, of Roden Bros., Toronto, has been elected chairman, and **L. L. Anthes,** of Anthes Foundry, vice-chairman of the Toronto branch of the Canadian Manufacturers' Association.

Lawn Smith, formerly of Dundas, Ont., has been appointed assistant engineer at the Curtis aeroplane works of Buffalo, N.Y.. Mr. Smith worked in the Chapman Engine Works at Dundas, Ont.

Fred W. Dunn, foreign manager of the Canada Cycle & Motor Co., Toronto, Ont., has sailed on a business trip from Vancouver, for New Zealand, Australia and the Orient. He will be absent six months.

W. Frank Hatheway has sailed from New York on the Kroonland for Europe. He is the only Maritime representative on the commission of Canadians recently appointed to inquire into the possibilities of after-the-war trade with Great Britain, France, Italy and possibly Belgium.

A. J. Moxhan, president of the Aetna Explosives Co., which has a plant at Drummondville, Que., has resigned and H. S. Kimball, president of the American Zinc, Lead & Smelting Co., has been elected president. Mr. Kimball will continue as president of the American Zinc, Lead and Smelting Co.

H. D. Scully, who has been secretary of the Canadian Manufacturers' Association and of the Munitions Section of the Canadian Manufacturers' Association, has resigned his position with these organizations in order to accept an important position with the Russell Motor Car Co. Mr. Scully will become secretary of the Russell Motor Car Co., and also secretary and a director of its subsidiary, the Canada Cycle & Motor Car Co.

Joseph A. Horne, a director of the Yale & Towne Mfg. Co., has been elected to the position of second vice-president, retaining also his present position and title of general superintendent. Mr. Horne, who has been over 24 years in the company's service, has the entire management of the works at Stamford, Conn., and of all manufacturing operations of the company, including those of its Canadian plant at St. Catharines, Ont.

Contracts Awarded

Ottawa, Ont.—The City Council have awarded the National Ironworks of Toronto, a contract for a quantity of cost iron pipe.

The Ferranti Co., have been awarded a contract by the City of Winnipeg for three transformers for the King St. substation of the light and power department at $9,650.

Burlington, Ont.—The town council have awarded a contract for a "Denby" motor fire truck to the Sherman Auto Garage of Hamilton, Ont. The truck complete with 200 ft. of chemical hose and ladders, etc., will cost $4,850.

Railways—Bridges

Fredericton, N.B.—The tenders for the construction of the uncompleted sections of the St. John Valley Railway are all in and the contract will probably be awarded shortly.

The Pas, Man.—Steel-laying on the Hudson Bay Railway on the last half of the road, was resumed on May 16 on the ninety-mile stretch between Manitou Rapids and Kettle Rapids. Contractors expect to have the track laid to Port Nelson by next summer at latest.

Name New Station "Petain." — In honor of the gallant French general who has been in command of the operations at Verdun during the terrific onslaughts delivered by the Germans, the junction point of the Kettle Valley Railway with the main line of the C. P. R., near the station of Hope, on the north side of the Fraser River, has been named "Petain." The appellation appears in the new summer schedules, which are now in the printers' hands, and will be issued shortly. The new time tables will become effective on June 4 as previously announced. The junction point of the Kettle Valley and the C. P. R. lines near Otter Summit, where the Spences Bridge branch of the latter road ends, has been designated Brodie as a compliment to H. W. Brodie, general passenger agent for the C. P. R.

Trade Gossip

North Vancouver, B.C.—A scheme is being considered by local interests which may result in a shipbuilding plant being established here.

Edmonton, Alta.—A workmen's Compensation Act is proposed for the Province of Alberta. It will likely be similar to a bill now before the B.C. Legislature.

Wiarton, Ont.—It is reported that the Crown Portland Cement plant will be sold, and instead of cement there will be manufactured magnesia, hydrate of lime, potash, etc.

Ottawa, Ont.—It is understood that the Canadian Northern Railway is in the market for equipment, and that contracts will follow the voting of the financial assistance now being asked from the Dominion Government.

Wallaceburgh, Ont.—The St. Clair Oil Co., a new concern just organized, with head office at Toronto, will take over and operate the Wallaceburg Oil Refinery in the near future. C. W. Yates, of New York, and R. G. Stitt, of Toledo, Ohio, are among those interested in the deal.

Barrie, Ont.—At the annual meeting of the Barrie Board of Trade held on May 19, the following officers were elected: Hon. president, P. J. Lynch; president, J. R. Hambley; vice-president, H. A. Sims; secretary-treasurer, Geo. D. Hubbard.

Rubber Seized.—Fourteen hundred parcels of rubber which were taken from the first-class mails on the Dutch steamer Gelria, while she was on her way from South America to Holland, were condemned in the British Prize Court on May 22. The parcels were said to be destined for Germany.

Saskatoon, Sask.—The Board of Trade may be represented at the conference of Chambers of Commerce of the Empire, to be held in London, England, on June 6, 7, 8, by Lt.-Col. H. W. Laird and

Major F. J. James. These two officers are at the present time on active service with the Canadian Army Service Corps in England.

Contract for Uniforms.—Contracts for 250,000 uniforms will be awarded by the Canadian Government within the next ten weeks, and will be shared by Canadian firms only. The drill and army duck required for these, it is said, can be obtained only from the Dominion Textile Co., so that it will add another to the many huge orders the Textile Co. are receiving.

The Sudbury Nickel Refineries, of Ottawa, has been Federally incorporated with a capital of $5,000,000. The company has the patent rights to a new process of nickel refining, and is said to be prepared to establish in Canada a big nickel refining industry, competing with the International Nickel Co., which is now arranging for a plant in the Maritime Provinces.

Bonus for Shipbuilding.—North Sydney, N.S., is going to make a bid for the establishment of a shipbuilding plant in the town. The council has adopted a resolution providing for the town furnishing a free site, tax exemption and other concessions tending to induce a company or persons to establish such a plant in the town: they even go so far as to offer a bonus.

Copper Refineries.—The ten copper refineries of the United States will have a combined annual capacity of 2,461,000,000 pounds upon the completion, within a few months, of increased facilities The plants of the American Smelting and Refining Co. and the Anaconda Copper Mining Co. will contribute the principal gains, the six refineries of these two companies to have a capacity of 144,000,000 lbs. of copper a month.

C. N. R. and Cunard Lines.—Cunard representatives visited Bristol recently and were given a reception by the Lord Mayor and the public bodies on taking over the Canadian Northern shipping. The new service will be inaugurated by the sailing of the Principello for Montreal. William Phillips, European manager of the Canadian Northern, expressed appreciation of the treatment of his company by the Cunard officials.

B. C. Boards of Trade Organize.—A special meeting of the Associated Boards of Trade of South-western British Columbia was held in the Vancouver Board of Trade rooms on May 13 to consider a resolution offered by the Vancouver Board of Trade providing for the organization of an association of Boards of Trade for the Province of British Columbia. The organization proposes to foster trade and assist in the development of the province.

Trade Commission Sails for Europe.—The Traveling Trade Commission, appointed by Sir George Foster, to visit Great Britain, France, Belgium, Italy and possibly Russia, has sailed for Europe, and will be absent for three or four months. Roy Campbell, a son of A. C. Campbell, of the Hansard staff of the House of Commons, and secretary of the Montreal branch of the Canadian Manufacturers' Association, is appointed secretary of the commission.

Government Orders Freight Cars.—It is understood that, in addition to the 30 locomotives ordered from the Canadian Locomotive Co., Kingston, Ont., for the Government Railways, orders for freight cars to the value of approximately $2,000,000 have also been awarded. The freight car order has been equally divided between the Canadian Car & Foundry Co., and the Eastern Car Co., New Glasgow, N.S. The cars are of a standard 50-ton type and are for use on the International Railway.

The Joliette Steel Foundries, recently destroyed by fire, has been taken over by a new company called the Joliette Steel Co. Kennedy Stinson is president., F. V. Moore, B.Sc., C.E., managing director, and G. B. LaForest, B.Sc., chemist The old plant has been rebuilt and remodelled with a capacity of 25 tons per day, to be immediately doubled however. A Bessemer converter has been installed. The head office is in the Read Building, Montreal, and operations started on the plant last week.

The Russell Motor Co., purposes to build a new factory at Weston, on twenty-eight acres recently purchased, to house the cycle and skate business. In the past, these branches of the company's activities have been handled in connection with the motor car plant at West Toronto. This has been turned over to the new Willys-Overland Co. of Canada, who require the whole premises for their business. Consequently the Russell Motor subsidiary, the Canada Cycle & Motor, must go elsewhere. The company is handling its fuse contracts at the city plant on Dufferin street. The factory, it is stated, will cost $100,000.

Grain Shipments.—The C. P. R. shows, in special publications, that 14,510,182 bushels of grain were shipped from Canadian ports at the head of the Great Lakes, during the last week in April, and that the total grain in store at the end of April, at the head of the lakes, was 28,197,921 bushels, compared with about 10,000,000 bushels a year ago. There is also much grain at inland points in the West, so that a busy season is anticipated. It is believed that the financial effects of the crop will be felt more this season than last, as the surpluses of wheat still unsold come upon the market.

May Subsidize Shipbuilding.—A subcommittee of the Cabinet is to be appointed shortly to deal with the question of the advisability and the means of Federal assistance for the development of the shipbuilding industry in Canada. This question was discussed on several occasions during the recent session, principally on behalf of the Canadian shippers, who have been encountering difficulties through the shortage of ocean tonnage. The appointment of a Ministerial Committee to deal with the question will be followed by a careful study of the problems surrounding the building up of a Canadian shipbuilding industry.

The Export Association of Canada, Montreal, which was organized a few months ago for the purpose of securing orders for Canada from the other portions of the British Empire and the Allied countries, has booked actual orders with Canadian firms within the past few weeks aggregating more than half a million dollars. This amount could have been increased many fold but for the scarcity of ocean transportation. That the association has been so successful in spite of the scarcity of space and the abnormally high prevailing freight rate should encourage Canadian manufacturers to prepare for export business. The association is sending a special representative to Siberia. He will go via Vancouver, and will open offices in Vladivostock, continuing his investigation and sales as far west as Omsk on the Trans-Siberian Railway.

Scholarships for C.P.R. Employees—George Bury, vice-president of the C.P. R., announces that two free scholarships, covering four years' tuition in the Faculty of Applied Science in McGill University, are offered to apprentices and other employees enrolled on the permanent staff of the said company, and under 21 years of age, and to minor sons of employees. The competitive examination will be held at the University, Montreal, and at other centres throughout Canada, in June. The candidates making the highest average and complying with the requirements of admission will be awarded the scholarships. The scholarship will be renewed from year to year, to cover a period not exceeding four years, if, at the close of each session, the holder thereof is entitled, under the rules, to full standing in the next higher year.

Plant Extension.—The Goldie & McCulloch Co., Galt, Ont., are making an addition to their South Works plant in the shape of a new power house. This will be thoroughly modern in every respect. It will be equipped with coal and ash handling apparatus, the coal being delivered to the bunkers direct from hopper-bottomed cars. The boilers will be

Goldie & McCulloch sectional water tube type, with superheaters and automatic stokers, and the engines will be Goldie & McCulloch vertical type, direct connected to d.c. generators. Besides the engines and generators, the engine room will contain the switchboard, a vertical air compressor and the usual condenser and feed pumps. These latter as well as the feed water heaters will be of Goldie & McCulloch make. A complete new hot water forced circulation heating system is to be installed for heating the present shop buildings. The pump for circulating the heating water will be of the centrifugal type driven by a Goldie & McCulloch steam turbine.

Refrigeration

Killarney, Man.—The Crescent Creamery Co., propose establishing a creamery here to cost $5,000. The town gives the company exemption from taxation on their plant for a period of five years.

New Incorporations

Edmonton, Alta.—The Alliance Power Co. has been incorporated to build and operate power plants, etc., $250,000 capital stock.

The Dominion Tygard Engine Mfg. Co., has been incorporated at Toronto, Ont., with a capital of $100,000 to manufacture steam or gas engines and accessories therefore. Head office at Toronto. Incorporators are Adam M. Cook and Irene House of Toronto.

The Miller Extracts, has been incorporated at Ottawa with a capital of $200,000 to manufacture, dyes, dyestuffs, tanning and other extracts. Head office at Montreal, Que. Incorporators, G. W. MacDougall, L. Macfarlane and W. B. Scott all of Montreal.

The Sarnia Creamery Co. has been incorporated at Toronto with a capital of $100,000 to manufacture ice cream and ice, and also pasteurize milk. Head office is at Sarnia, Ont., and the incorporators are: R. Sharpe, T. H. Lucas and J. W. Lawrence, all of Sarnia, Ont.

The Chemical Products of Canada, has been incorporated at Toronto, Ont., with a capital of $40,000 to carry on business as manufacturers of chemicals, drugs, colors, dyes. Head office at Toronto. Incorporators are Terence E. O'Reilly and George G. Grover of Toronto.

The Three Rivers Cold Storage & Ice Co. has been incorporated at Ottawa with a capital of $50,000 to carry on a cold storage and ice business at Three Rivers, Que. Incorporators: S. Malone, A. J. Gouin and F. H. Mahone, all of Three Rivers, Que.

The Shimer Cutter Head Co., of Canada, has been incorporated at Ottawa, with a capital of $50,000, to manufacture cutter heads, machine knives of all kinds at Galt, Ont. Incorporators: F. H. Palmer, Robert Polloch and Wardlaw Vair, all of Galt, Ont.

The Sanitary Heating and Ventilating Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture electrical and heating appliances of all kinds. Head office to be situated at Ottawa. Incorporators: A. E. Adams, O. G. J. O'Regan, and J. H. Barker, all of Ottawa.

The National Wood Manufacturing Co. has been incorporated at Ottawa with a capital of $25,000 to operate mills for the working up and manufacturing of lumber and wood. Head office to be situated at South River, Ont. Incorporators: W. J. Ard, C. A. Jackman, and Albert Howard, all of South River, Ont.

The Lambton Flax Co., has been incorporated at Toronto, Ont., with a capital of $40,000 to carry on the business of flax, hemp and jute spinners, linen manufacturers. Head office at Petrolea, Ont. Incorporators are Richard V. LeSueur and Antony I. McKinley of Sarnia, Ont.

The Canada Clock Co. has been incorporated at Ottawa with a capital of $250,000 to manufacture clocks, electrical master clocks, electrical clock systems, etc. Head office to be situated at Toronto, and the incorporators are: E. M. Dillon, H. R. Frost and A. E. Grosch, all of Toronto.

The F. S. Carr Rubber Co. of Canada has been incorporated at Ottawa with a capital of $200,000 to manufacture rubber, automobile and carriage fabrics. Head office to be situated at Granby, Que., and the incorporators are: J. E. Day, J. M. Ferguson, and J. P. Walsh, all of Toronto.

The Detroit Mica Mining Co. has been incorporated at Ottawa with a capital of $150,000 to acquire and develop mineral lands and deposits. Head office to be situated at Windsor, Ont. The incorporators are: M. Harris and P. A. Miller, of Detroit, Mich., and J. Robinet, of Sandwich, Ont.

The Mutual Chemical Co., of Canada, has been incorporated at Ottawa with a capital of $49,000 to carry on the business of mining, milling, concentrating, in all kinds of ores. Head office at Sherbrooke, Que. Incorporators, C. W. Cate, J. P. Wells and C. D. White all of Sherbrooke, Que.

The Milton Pressed Brick Co., has been incorporated at Toronto, Ont., with a capital of $1,500,000 to manufacture every kind of brick and build-

ing materials and supplies. Head office at Toronto. Incorporators are Arthur W. Holmsted and Norman R, Kay of Toronto, Ont.

The Majestic Electric Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture electric, gas, or other heaters, and electric supplies of every description. Head office to be situated at Toronto. The incorporators are: A. L. McLennan, R. McLennan, and J. A. Campbell, all of Toronto.

The Mutual Chemical Co. of Canada has been incorporated at Ottawa with a capital of $49,000 to carry on the business of mining, milling, smelting of all kinds of ores, etc. Head office to be situated at Sherbrooke, Que. Incorporators: C. W. Cate, H. P. Wells, and C. D. White, all of Sherbrooke, Que.

The Canadian Drawn Steel Co. has been incorporated at Ottawa with a capital of $500,000 to carry on the business of steelmakers, steel converters, steel drawers, etc. Head office to be situated at Hamilton, Ont., and the incorporators are: R. K. Hope, H. J. Waddie, and S. D. Biggar, all of Hamilton, Ont.

The Vulcan Asphalt & Supply Co. has been incorporated at Ottawa with a capital of $10,000 to carry on the business of manufacturing building materials, paper, asphalt, oils and other mineral substances. Head office to be situated at Winnipeg. The incorporators are: R. F. McMillin, W. A. Stapley, and J. H. Russell, all of Winnipeg.

The Quality Canners of Canada have been incorporated at Ottawa with a capital of $250,000 to carry on business as a manufacturer of preserved fruits and vegetables, pickles and soups, etc., at Windsor, Ont. Incorporators: E. C. Awrey, of Leamington, Ont.; Wm. Henry Furlong, of Windsor, Ont., and W. Wall, of Merlin, Ont.

The Globe Shock-Absorbing Tire Co., of Canada, to be incorporated at Toronto, Ont., with a capital of $1,000,000 to manufacture a resilient or shock-absorbing vehicle, automobile and commercial tire. Head office to be at St. Catherines, Ont. Incorporators are Isaac Normandy and Howard J. Ecclestone of St. Catherines.

The Canadian Fire Hose Co., has been incorporated at Ottawa with a capital of $40,000 to manufacture fire apparatus and extinguishers, including signal systems. Head office to be situated at Montreal, Que. Incorporators, S.H.R. Bush, J. S. Lamarre and E. C. Baker all of Montreal.

The McArthur Belting Co. has been incorporated at Ottawa with a capital of $40,000 to acquire the business of D. J. McArthur & Co., manufacturers of

leather beltings. Head office to be situated at Brockville, Ont. Incorporators: J. D. McArthur and J. S. McArthur, of Brockville, Ont.

The Sudbury Nickel Refineries, has been incorporated at Ottawa with a capital of $1,000,000 to carry on the business of producing, reducing, refining ores, metals, etc., and all other reducible substances. Head office to be situated at Ottawa, Ont. Incorporators, L. P. Burrows, E. Seybold and W. C. Perkins all of Ottawa, Ont.

The Dominion Ivory Co. has been incorporated at Ottawa with a capital of $50,000 to manufacture ivory imitation goods, waterproof goods, rubber, cotton goods and fabrics, etc. Head office to be situated at Toronto. Incorporators, S. L. Kenyon and H. R. Bemis of Springfield, Mass., and Newton O. Harvey, of Toronto.

The Goderich Manufacturing Co., has been incorporated at Toronto, Ont., with a capital of $100,000 to carry on a general manufacturing business, including therein all kinds of woodenware, furniture and articles which can be manufactured out of wood or iron. Head office at Goderich, Ont. Incorporators, are John E. Baechler and Jacob J. Baechler of Goderich, Ont.

The Studebaker Corporation of Canada has been incorporated at Ottawa with a capital of $400,000 to manufacture automobiles, boats and vessels operated or controlled by electricity, gasoline, steam, gas, or compressed air. Head office to be situated at Walkerville, Ont., and the incorporators are: C. DeLacy Fleming, of Detroit, Mich.; A. Leslie and H. L. McDowell, of Walkerville, Ont.

Marine

Ottawa, Ont.—The estimates include an appropriation of $100,000 for the construction of a pier at Port Stanley, Ont., and $32,000 to repair the piers at Port Burwell, Ont.

Chatham, Ont.—The announcement has been made by the Hon. Robert Rogers, Minister of Public Works, that the Government will take steps to dredge the River Thames to a depth of fourteen feet.

Port Arthur, Ont.—The Massey Steamship Co. has purchased the United States-owned steamers Panther and Caledonian, and will put them under Canadian register and in the Canadian lake service.

Yachtsmen Enlist.—About eighty Toronto yachtsmen has joined the Royal Naval Auxiliary Patrol Motor Boat Service, for which recruits are being enlist-

ed by Commander F. P. Armstrong, R. N. V. R., at his office in that city.

Vancouver a Grain Port.—On May 19, for the first time, the machinery of the new Dominion Government grain elevator at Vancouver handled grain. Two cars of wheat were unloaded and stored, and Vancouver entered upon its career as a grain handling port.

Ottawa, Ont.—Supplementary estimates tabled in the House of Commons on May 2 include an additional $200,000 for Vancouver harbor, $200,000 for Fraser River improvements, and $20,000 for improvements to the lower Fraser. There is also a vote of $32,500 for telephone line extensions.

Ice-Breaker Launched. — The icebreaker "J. D. Hazen," built by Canadian Vickers to the order of the Dominion Government for service on the Lower St. Lawrence, was successfully launched on Monday afternoon, May 15. Lady Borden, wife of Canada's Prime Minister, performed the christening ceremony.

Canadian Lumbermen for England.—Fifteen hundred Canadian lumbermen have gone to England to cut timber for railway ties, pit props, and other purposes and within a few weeks an important result is expected from this experiment in saving the import of foreign timber with its attendant demand on tonnage.

Cobourg, Ont.—It is stated that the steamer Caspian, formerly on the route between Charlotte and the Bay of Quinte, has been withdrawn. The Bay route to Charlotte has long been in use and, if abandoned, will mean that travellers will have to cross the lake at either Kingston or Cobourg. This route was a feature of the Gildersleeve Lines for more than thirty years.

Insurance Against Peace Declaration.—London underwriters on May 23 charged 50 per cent. to insure against a declaration of peace between Great Britain and Germany before January 1. The rate indicates that in the underwriters' opinion the prospects for an early peace are better than two months ago, when the rate for the same risk was only 30 per cent.

Docks for Point Edward.—Grand Trunk engineers have been in the city for the purpose of taking depths of water in the river at Point Edward, where the company is to build a 1,000-foot dock and freight shed for the Port Huron & Duluth Steamship Line. These boats formerly landed in Port Huron, but the sheds there were destroyed, and Point Edward was picked as a better location for the new sheds.

Port Arthur, Ont.—Reports from Port Arthur state that the Western Drydock & Shipbuilding Co. has received a con-

tract for the construction of fifty motor boats for the British Government. Five carloads of steel recently arrived at Port Arthur to be used in the construction of two freighters, the contract for the construction of which was received by the company a short time ago. The Russian Government is also reported as placing a contract for the construction of six icebreakers, three of which will be built at the head of the lakes.

Quebec Pilots and Apprentices.—A bill has been introduced in the House of Commons, amending the Canada Canada Shipping Act as regards pilots and pilot apprentices in the Quebec Pilotage District, and providing that the number of pilots for that district shall not exceed 125, and that when the apprenticeship period of a pilot has been interrupted by sickness or other legitimate cause, he may be allowed to serve an additional period equal to the time lost, and if found otherwise qualified and entitled to a license, he may be granted such license after he has completed a full service period of seven years including the additional period.

Mercantile Losses in February. — The Bureau Veritas has published statistics concerning losses to the various mercantile marines during February on account of the war: During the month 47 ships of a total tonnage of 105,232 were lost. The loss of 26 ships of a total tonnage of 56,345 tons was due to submarines or mines, 9 ships of 16,165 tons to auxiliary cruisers, and one of 957 tons to a Zeppelin. England has been the greatest loser, 27 of her ships of a total tonnage of 58,000 tons having been destroyed. Other nations lost ships as follows:—France, 7 of 25,000 tons; Belgium, 4 of 6,710 tons; Russia, 2 of 4,108 tons, and neutrals, 7 of 10,000 tons.

To Restrict Sealing.—As a direct result of one of the most successful seal-hunting seasons on record, the Newfoundland Legislature has enacted restrictions designed to prevent the extermination of the animals in the waters about the Island. Large steel steamers, such as have been used extensively during the last few years, are now prohibited from engaging in sealing. Most of these vessels were sold to the Russian Admiralty last year for use as ice-breakers, but one, the Florizel, has brought in 46,000 pelts, the largest number ever secured by a single ship, and yielding a profit of $130,000. The new restrictions will make it impossible to use a vessel capable of carrying more than 25,000 pelts. The total catch for this season was 295,000 seals, valued at $650,000.

Lloyds' Registry Appointment.—The Committee of Lloyds' Register have appointed James French, principal surveyor at Glasgow, to the position of prin-

cipal surveyor for the United States and Canada, with his headquarters at New York. Mr. French, who served for a considerable time previously on the American staff of the Register, has already undertaken his new duties. He was among those present at the launch of the new ice-breaker, "J. D. Hazen."

Japanese Business Booming.—Industry in Japan is booming as a result of the war, an dthe enterprising among the citizens are securing a considerable portion of the business formerly done by the German and other merchants and manufactnrers. As the Japanese know how to hold on to a thing when they get it, it is to be taken for granted that they will relinquish little if any of their newly-won trade after peace is declared.

Catalogues

Waugh Glazing Construction is the title of a Bulletin No. 56 describing the product of the Asbestos Protected Metal Co., Pittsburgh, Pa. The distinguishing features of this system of construction are dealt with fully, and are further explained by means of a series of detail drawings. A number of excellent half tones show various classes of building where the "Waugh" glazing has been installed.

Grinders.—The Challenge Machine Co., Philadelphia, Pa., hase issued a bulletin illustrating and describing the "Challenge" grinders. Sixteen of the various combinations of these grinders and several units are shown accompanied by a description covering their principle features. Tables are included giving dimensions for the various sizes of grinders, also dimensions of columns and countershafts.

Notes on Screw Gauges.—The National Physical Laboratory has published some "Notes on Screw Gauges," giving the results of experience in testing same. It is written by the staff of the Laboratory, and deals particularly with some of the difficulties which occur in manufacture and testing. Simple methods of measuring the principal elements of the gauge are described, and the need for making some of these measurements during manufacture, are explained. Many subjects are dealt with, these including: The need for accuracy in a Gauge; Verification of Screw Gauges; Errors of Screws; Measurement of the Diameters of Plug Screws; Notes on Tools; Measurements of Ring Screw Gauges; Measurements at the Lathe; Pitch error; Measurement of Angle of Plug Screws; Measurements of Effective Diameter; also Angle of Cylinders of other than "best" diameters, data for measurements.

CANADIAN MACHINERY

AND MANUFACTURING NEWS

A weekly newspaper devoted to the machinery and manufacturing interests.

Interesting Type of Canadian Built Oil-Driven Tractor

Staff Article

The internal combustion engine possesses certain features, such as ease of fuel supply, small consumption of water, portability and safety of operation which render it peculiarly adapted as a prime mover for agricultural machinery. Not only in this country does the convenience of liquid fuel give this type of engine a marked advantage over steam, etc., but in nearly all the principal grain-growing countries of the world similar conditions obtain.

AN important factor in the development of the agricultural resources of the various grain growing countries has been the ever-increasing adoption of mechanical power not only for cultivation of the soil but for the performance of much work which has hitherto demanded arduous physical labor when done by hand, or has involved the use of animal power, both of which sources are less efficient, more strictly limited in output, and in the case of the former are sometimes completely unobtainable. Under these circumstances the development in this country of power generating apparatus specially adapted to the conditions outlined has been of steady and consistent growth.

Mechanical Power Favored

The phenomenal development of motor cars and their adoption by people in every line of business has so thoroughly familiarized every power used with the principles of construction and details of operation of internal combustion engines, that the use of motor driven agricultural machinery, factory power plants, domestic apparatus, and municipal equipment has developed to such an extent and the benefits so fully recognised, that physical labor is rated at its true worth and discarded in favor of mechanical power wherever possible.

For the past fifteen years, the Goold, Shapley Muir Co., Brantford, Ont., have devoted a large part of their energies to the production of internal combustion engines using gas, gasoline and oil as fuel, and have developed various types of engines capable of efficiently performing all the various duties required of such machines as may arise in the course of work, be it a farm tractor cultivating acres of ground daily, a small inconspicuous engine driving water pumps of all descriptions, grain grinders, saws, cream separators, etc. or a carefully tended high powered engine of special design supplying power to electric light plants, planing mills and factories of all kinds.

A moderate powered engine, typical of the general design of horizontal unit built by this firm is illustrated in Fig. 1, which shows the exhaust side of a hopper cooled engine the combination of the cooling water tank, with the cylinder casting being a feature which possesses many advantages where portability is desired. The engine is shown mounted on skids which facilitate its transportation when occasion arises, although when the full degree of portability is desired these engines are mounted on steel frame work on wheels.

Single cylinder engines in eleven sizes up to 25 horse-power and double cylinder engines of opposed type, in seven sizes from 18 horse-power to 60 horse-power are built with various methods of water cooling.

Farm Fractors

Tractors for farm use are built in two sizes 35 and 50 horse-power, the opposed type of engine being well adapted for this class of work. A view of the right side of the larger machine is given in Fig. 2 and a view in course of assembly is shown on Fig. 3, the arrangement of the principal members being clearly shown. The

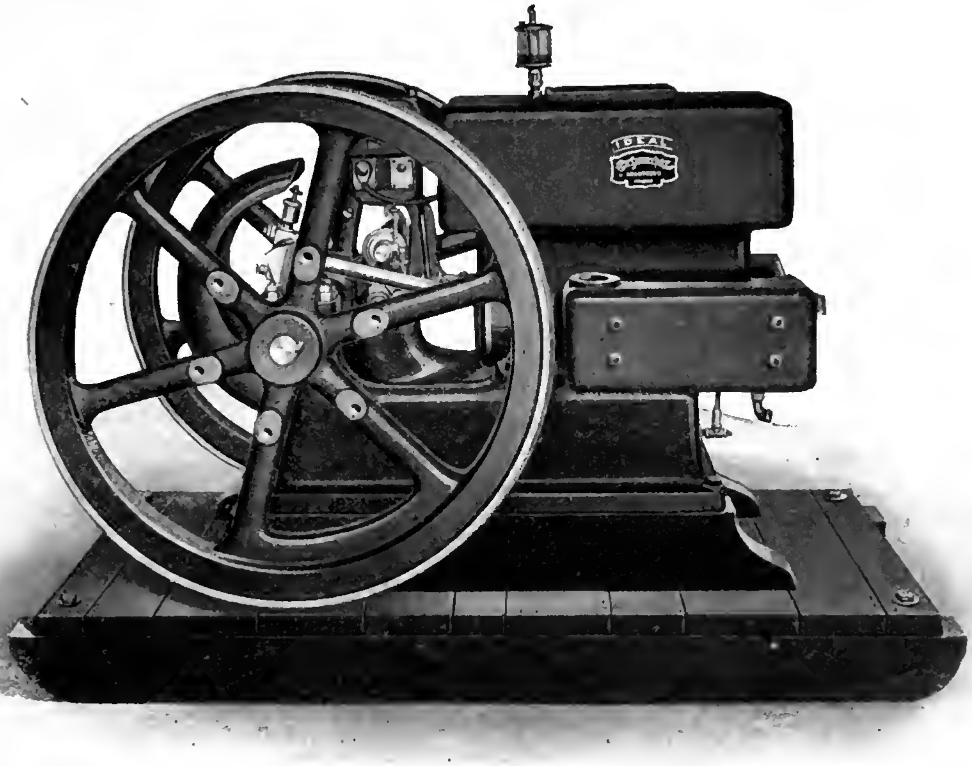

FIG. 1—EXHAUST SIDE OF HOPPER COOLED ENGINE MOUNTED ON SKIDS FOR TRANSPORTATION.

main frame is formed of two heavy steel channels to which the engine is fastened, the width of the frame at the front allowing of ample steering

FIG. 2. RIGHT SIDE OF 30 HORSE-POWER TRACTOR SHOWING THRESHING PULLEY WITH SELF-CONTAINED CLUTCH GEAR.

lock to the front wheels, while the rear end of the frame is widened out to form a support for the driving platform.

Two forward speeds are provided, a road speed of 4 miles per hour, and a plowing speed of 2 miles per hour with similar reverse. The forward and reverse speeds are obtained by the movement of a single lever seen projecting above the driving platform in Fig. 2. The lower end of this is coupled to a vertical shaft just in front of the clutch pulley, which by means of a cam plate as shown in Fig. 5 operates either of a pair of band clutches to give the desired direction of travel. The two views in Fig. 4, show the clutch details, the principal parts being the engine shaft A which carries the assembly—driving pinion B keyed to shaft A— planetary pinions C mounted on reverse clutch D and forward clutch E which carries an internal gear F, meshing with the planetary pinions, an outer rim G for driving by belt, and a double gear H mounted on the hub extension formed integral with E.

Action of Clutch

Assuming the shaft to be revolving toward the reader, the action of the gearing will be understood by supposing both clutch bands to be slackened. Driving pinion B will cause the planetary pinions to revolve on their shafts so that along with the reverse clutch D, they will move in the same direction as the engine shaft, but without imparting motion to any other parts. The forward clutch band however, is tightened by means of a lever I which is mounted on the reverse clutch, and is operated by a spool sliding on the hub of reverse clutch D, and when this is done, the result is to lock both clutches together so that the pinions cannot move in relation to the internal gear and consequently the entire assembly is driven round by driving pinion B in contact with the three planetary pinions. When the forward clutch band is released and the reverse band tightened, the latter, being anchored to the engine bed, prevents the planetary pinions from traveling around with driving pinion B, which accordingly drives the planetary pinions in a reverse direction and through them the internal gear F with its rim and double gear. The double gear is used to obtain the two speeds by sliding it along the shaft as shown by dotted lines, the difference in diameter being compensated for by an idler gear on a swinging arm which is raised to mesh with either gear after changing speeds. This arm and idler gear can be observed in Fig. 3, being located immediately below the clutch pulley; the idler meshes constantly with the large spur gear in the centre of which the differential mechanism is assembled.

Differential Gear

The differential bevel pinions are fitted with grease cups supplying lubricant direct to points of greatest pressure. The heavy spur pinion on the outside of the differential gear meshes with the internal gear mounted on the side of

FIG. 3. TRACTOR IN COURSE OF ERECTION, SHOWING SUBSTANTIAL CONSTRUCTION OF REAR AXLE DRIVING MECHANISM.

the large road wheels, see Fig. 2. The rear axle is formed of solid steel shafting strongly reinforced by steel castings built into the frame at this point, the driving wheel being assembled on the projecting portion of the shaft shown in Fig. 3.

An outline drawing of the engine and clutch is reproduced in Fig. 5, while details of carbureter and steering gear are given in Fig. 6 and 7. Fig. 8 and 9 show left side and back view respectively of the complete tractor.

The carbureters of which there is one to each cylinder are adapted for the use of kerosene and give satisfactory results in use. The bowl below the atomising tube is jacketed with hot water from the cylinder, the flow of fuel being regulated by the needle valve from the outside, the venturi tube type of passage responding to variations in demand as affected by the butterfly throttle valve which is operated from the engine governor. An automatic injection valve controls a supply of water to the carbureters for use in the cylinders

The engine is fitted with jump spark ignition of a type which gives as full spark when turned over slowly as when running at speed, thus facilitating starting.

Steering Gear

An underneath view of the frame is given in Fig. 7, the flexibility of the front axle being well shown. The operator controls the steering from a vertical hand wheel through worm and gear to the pinion located between the two racks in Fig. 7. These racks are slidably mounted in a guide plate and as they both mesh with the pinion, they travel in opposite directions when the pinion is revolved, thus causing the front wheels to assume the desired position when turning to either side.

The front axle is of strong bar construction the rear member being extended backward where it is supported in a pivot bearing in line with the front bearing. Free movement of the axle is thus assured under the worst of

road conditions without causing undue stress in the engine, or frame. Corrugated ground locks are mounted on the driving wheels, providing ample grip in

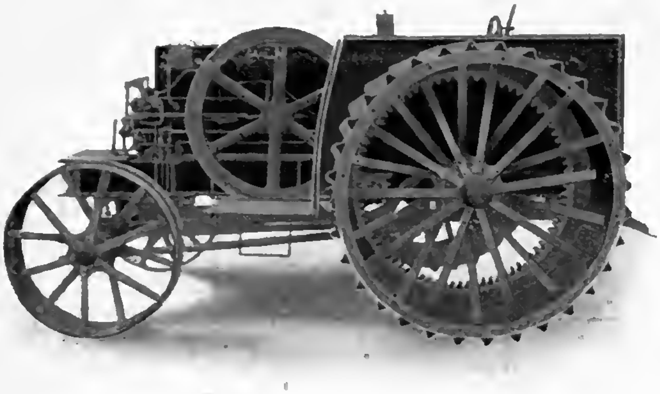

FIG. 8—LEFT SIDE OF TRACTOR.

heavy going and avoiding cutting of the sod. Both front and rear wheels are of riveted steel plate and bar construction. Bronze bearings are used throughout and steel castings for the transmission gears.

Contractors' Plant

The adaptability of small power internal combustion engines to the performance of much work previously done by hand is particularly marked in the case of contractors' machinery, of which concrete mixers, hoisting machinery, pumps, stone breakers, etc., are familiar examples. The production of such machinery provides a considerable demand for motive power, and in the case of the firm in question maintains a balance of activity in the smith shops and running gear departments, which are necessary for tractor building. Figs. 10 and 11 show two views of a concrete mixer driven by a $2\frac{1}{2}$ horse-power vertical engine, the outfit being designed to meet the requirements of contractors on small jobs. The entire construction is of steel, the truck frame being 7 ft. 8 in. long, with a clearance of 19 in. above ground,

FIG. 9. REAR END OF TRACTOR.

and a tread of 4 ft. 2 in. Steel wheels, with 3 in. wide tires, are fitted to built-up axles of channel steel.

The mixing drum is 36 in. dia. by 26 in. wide, and is encircled by a 3 in. wide gear ring, which revolves the drum on four rollers.

Capacity

The capacity of the mixer is a 4ft. or $\frac{1}{2}$-bag batch, fifty yards being easily mixed in ten hours. The drive to the drum pinion is through a positive clutch, which is provided with a friction device for taking up the drive before engaging positively.

A tilting chute is arranged on the discharge side of the mixer, and when not in use, this points downwards into the mixer enabling water to be conveniently introduced. When discharging, the chute is tilted towards the outside, as shown in Fig. 11, the mixture being deposited on its inner end as the blades carry it around, and thence falling down the chute which is of a convenient height for discharging into wheelbarrows. The engine is protected by a steel housing, not shown in the cuts, and the complete outfit with tongue for team weighs 2,200 lbs.

BRITISH BUILT MACHINERY

IN a recent report on the trade of Finland, the British Consul, comparing the respective merits of German and British machinery, said that German goods had very much improved in quality during the last few years, and in many branches were beginning to compare favorably with British goods, especially as regards machinery.

British machinery seemed to be almost too strongly made, and was practically never worn out. The Germans, on the other hand, appear to aim at making machines which would last a certain number of years, and work out the exact structural strength required accordingly, one result being that their machinery could be sold at a good profit, though at a cheaper price than the British article. As an instance in point it was stated that a firm in Finland recently bought two steam engines, one of British and the other of German make. Both worked very well. The German engine was, however, much more economical, of modern design, good workmanship and lower in price.

The British machine would probably last longer, but would become more and

FIG. 11. DISCHARGE SIDE OF CONCRETE MIXER SHOWING TILTING CHUTE.

more out of date compared with new designs put upon the market every year. On the other hand, when the German machine was ready to be scrapped, it was reckoned that money would be saved by buying a new engine embodying improvements which experience had in the meantime suggested.

BRITAIN AND ENEMY-SEIZED SHIPS

A NET gain of $24,250,000 has been realized by Great Britain from their seizure of enemy ships and their cargoes in the last twenty months of the war, according to the record of the Prize Court. The Government has captured 157 ships, which have been disposed of after decision by the prize court as follows:

	No.	Tonnage.
Sold	42	54,772
Requisitioned	42	56,162
Detained till after the war and requisitioned	73	85,036
Total	157	195,970

The results of the sales have been approximately: Proceeds of condemned vessels and interests, $1,674,025; expenses of sale, $26,540; total proceeds of

FIG. 10. LOADING SIDE OF CONCRETE MIXER SHOWING BELT DRIVE AND CHARGING HOPPER.

sale of ships and cargoes, $24,250,000. There are many more vessels and a large quantity of cargo still before the Court.

ECONOMIES IN SHOP MANAGEMENT

By H. Womersley.

JUST as we possess "fixed opinions," "set notions," etc., regarding the greater problems of life, so we possess a multitude of set notions regarding the best form of machinery and best methods of conducting a manufacturing business. Many of these notions have been acquired without careful thought. They have just been absorbed from our experience and environment. In some cases we may have assumed that someone has previously given the matter proper consideration, and that the existing conditions are the result of their conclusions. As a matter of fact, many of the conditions now existing in the machine shop are the result of allowing old practices to continue after conditions have changed, and this has taken place without the attention of anyone.

There is no desire to belittle the opinions of others; in fact, we must depend on others for most of our opinions; but there are so many things that have been left to "others," apparently by everybody, that it is well for us to do some independent thinking, especially on our own immediate problem, and cast a glance at least at some of our notions, just to see if they bear proof of having been thoughtfully produced, or unthinkingly allowed to take form. For years engineers have concentrated energies on the steam engine of the reciprocating type. The master minds have made important improvements in the design, and many have given up their entire existence to the science of analysing the effects of each variation in conditions of working the steam. Our text-books, our teaching, our observation, all concentrated our attention on this type.

Opportune Application

For some reason Gustav De Laval and C. A. Parsons broke away from this spell, and now we have the steam turbine engine. These two individuals are endowed with master minds, but the task of producing the turbines was probably no greater than the task of others in improving the reciprocating type. In one case a great step has been taken; in the other, we have an example of men of undoubted ability laboring hard for entire lifetimes with relatively small gain. This example applies to more than the inventors' world. It has many parallels in the cold businesss management of a manufactory or one of its departments. Business management requires the same kind of reasoning and getting away from the spell of environment.

The best plant of management cannot be obtained from history. The vast store of data of correct practice of former times will not serve the purpose. A record of the practice of even the last decade is inadequate, for rules of the game are continually changing.

The investment in a machine building plant and business is not wholly protected by fire proof buildings and ultra conservative management. The security must be protected by conducting the business on profitable lines. Safeguarding the money tied up in machinery equipment and buildings is important but should not lessen the consideration of elements which have to do with the expense of operating. A plant and business is useless when not in motion, and when under headway requires money. Money must be poured into it steadily. The amount every year generally equals the total capital in the business. Money invested in plant is not very safe if there is a tendency to squander the energies over too many problems.

Variety Product Handicap

The manufacture of a great variety of articles in response to a demand by the selling organization of a company is a relic of other days. Our notions about methods for selling must be changed over to fit the modern scheme. They must be kept up-to-date. The survival of the fittest will eliminate all, except ing specialists or groups of specialists.

The entire cost of conducting a business may be lowered by simply continuing along with the same men. This applies to the entire organization from the workmen to the salesmen. Changes should be made to keep up a wholesome spirit of progress. Men should be advanced from position to position as the opportunities afford and their endowments allow. Others unfortunately must be dropped out from the organization; but both the advancements and the weeding out must be carefully considered.

The management's chief business should be to take men as they are found on earth; mould as much as possible, and place each one where he will accomplish the best results for both the organization and the individual.. Barring the disgruntled, the uncongenial and the habitually inattentive, almost all men may be and should be profitably employed, the prime requisite being reasonably close attention to business. The thoughts must not habitually wander away from the work.

The management does not "manage" if it perpetually changes its men. It should bolster up the men who lack self confidence; it should puncture false ambitions, and it should use men as they are found in the organization. It should not be inclined to "go back on" a man who has blundered or who has been found lacking in understanding. It should not be over ready to embrace a stranger just because his faults are not known.

All business is pushed forward by men who have confidence in the project and in the product. If these men lose their faith in their own business, they not only lose their usefulness as pushers and managers, but they become drags on the industry, and remain so until restored to normality.

Suppositious Knowledge

The designer may have had almost complete knowledge regarding the best way to make each part, just how each fit should be made, and just how the machine should be operated under each combination of conditions, but it is more probable that the designer never had all this wonderful knowledge. If he knew all this, it would be of value providing he had some perfect way of imparting his knowledge to each individeual worker. We know, however, that this is impossible, even with the most thoroughly organized companies. It takes years to get each piece made as it should be made, even with no change of design, and this is not accomplished by any other process than continual practice, which is only acquired by making these pieces. The quality and speed of production increase with this experience and are not acquired without it.

A Rational Policy

The art of assembling and operation of the machine is developed in the same way. There are other means that facilitate, but nothing that takes the place of practice. The knowledge of the machine must be not only in the designer's head; it is not even enough to have it thoroughly known by all officers, including foremen. It must be patiently transmitter to the real workers.

One of the most satisfactory policies of management is that which tends toward getting the best return or profit per dollar of investment. The best scheme of management for profit is one that puts the capital where it will do

most good. One of the most common errors in this respect is the one that regards the reduction of labor costs as the paramount consideration. Reduction in labor cost has been the war-cry. The labor bill has been talked about so much that it has seemed to be the whole thing. What is the gain if the means for reduction of the net labor cost reduces the profit more than the saving in labor? If doing so results in an actual loss of profit, why is it done?

The cost of the product of the average plant may be divided into three nearly equal parts: the material, the labor and the burden: or, in four equal parts, if a reasonable interest charge is made for the use of the capital invested. The material is the iron, steel and other material that enters into the construction of the machine, and it is taken in the condition in which it usually comes to the machine shop. The burden includes all expenses and salaries necessary for the maintenance of the business. About one-half the amount paid for labor goes to the men who run the machine tools. Therefore the cost of labor is either one-sixth or one eighth of the total cost. On top of the net cost of the product there should be a profit. If it is not there, the sooner something happens the better. If it is there, then it is proportioned to the volume of the output. Therefore, both the size of the output and the labor cost should be kept in mind.

Stock Turnover

The dividing line between excessive and insufficient stock must be drawn in each individual case. An excessive stock of this or that piece, or of all pieces, means that much capital is idle, and it also tends to slackness of management. Frequently it is the outcome of carelessness. If money is to be retained in the business, it should be put into changing over the system to one which will conform to the plan of putting the money where it will bring the best return. The excessive stock in process is an outcome of blind progressiveness—the blindness that fails to see that there is as much money tied up in stock in process and in finished product as there is in the entire machinery equipment.

An adaptable equipment facilitates keeping down the amount tied up in stock in process. The modern plant should take advantage of these modern methods and machines which tend toward profitable use of capital. Such machines are highly developed and true to the controlling ideal of adaptability and largest output per dollar of investment.

CONCERNING ANTIMONY

ANTIMONY sulphide has long been in use by the Chinese as a coloring matter in the manufacture of pottery and in the ceramic arts. It is also largely used in making anti-friction matches, which contain about 25 per cent. on the match and 55 per cent. in the smear on the box.

Antimony is also extensively used for printing type and for anti-friction metal and bearing metals. English type metal is an alloy of antimony, lead and tin. Britannia metal consists of tin, antimony and zinc. Pewter contains tin, antimony, copper and bismuth, and anti-friction metal is usually composed of copper, antimony and tin. Antimony is employed in the manufacture of paints and colors.

Antimony white has recently come to be employed in the manufacture of enamel for household utensils, bathtubs, etc. Japan imports large quantities of antimony from China, which is manufactured into numerous artistic articles of daily use, glove and cigarette boxes, the backs of hand-mirrors and hair brushes, cigarette and card cases, statuary, ornaments, etc. Recently the value and need of antimony in the manufacture of explosives has become well known.

STEEL AND MALLEABLE IRON CASTINGS

THE choice between steel and malleable iron castings is dictated by their respective properties, partly by price, and partly by the limitations of the processes by which malleable iron is made. As pointed out in a paper read before the International Engineering Congress, steel is, in its nature, a more homogeneous metal, and, therefore, tougher and stronger than malleable iron. Moreover, castings of malleable iron are somewhat prone to actual porosity or sponginess at the centre, especially in certain portions of irregular castings, so that for this reason also a steel casting is stronger and more reliable. Finally, malleable iron can be made only into castings of quite light sections, whereas there is almost no limit to the size and weight of steel castings that can be produced. For uses where only a fair amount of strength and toughness is necessary, the castings being therefore of light section, it often pays to have them malleable, because they are cheaper than steel.

PIECEWORK SYSTEMS—III.

By R. R. Clarke.

BEFORE concluding this series of articles, I cannot refrain from submitting a few remarks on the premises from which an equitable piece-price is derived, and we throw our sincere belief in the spotlight when we assert that none except a man thoroughly acquainted with the ins and outs and closest details of the trade along with that of the local equipment is competent to pre-judge the worth of any piece of work to the doing of which that trade applies. We are not a foe to the efficiency expert or his aim, though in all candor we deplore many methods complementary to his system. We firmly believe in a test but we believe as firmly that the stop-watch man never made a fair one, neither to the man or the firm in whose interests he operated. To the realization of such the confidence and co-operation of human nature is absolutely essential, and that time the stop watch has never ticked nor can it ever. Our idea of a fair test differs from that of a man who watches a man 10 minutes, stops his watch, counts the output, multiplies by 60 and divides the product into 300 cents to arrive at a fair piece-price, and we are satisfied that the great underlying principles of human nature, troubled and resentful thereto, establish the justice of our differing opinion.

Determining a Fair Price

We remember a test to the supervision of which we were once assigned. The object was to derive a fair price on an improved machine connected with foundry production. The idea pre-conceived by the manager was that the machine was at least a 50 per cent. all around improvement over the one it displaced. The figure capacity of the old machine was 300. Giving the workman ample time to become thoroughly acquainted with the new machine, a test was decided on. The evening before the day chosen, I examined the machine and found it in good order. On the morning of the day's test I walked over to the machine shortly before 7 a.m., called the workman to one side, and told him that the object of the day's work was to make a fair test of the reasonable capacity of the machine, that a piece adjustment would follow, that in making the test I expected no breakneck speed, and at the same time would tolerate no unreasonable delays. I closed this preamble by expressing the hope that there would be no occasion for recurring to the subject and the test was on.

The output desired was 600. At noon the 400 mark was passed, one o'clock showed the spirit neither lacking nor lagging, and at 3 p.m. the work was done. If ever a workman practically volunteered the best that was in him, that fellow did and why? Because the "open and above board," "strictly on the square principle" appeals to human nature and brings out the best that is in it.

The aforementioned constitute the underlying principles on which most foundry piece-work systems are constructed and can be applied to the advantage of all. Fair prices, courteous firmness, just consideration and a sincere desire for mutual advantage will open the way to the system's efficiency.

Simcoe, Ont.—Fire destroyed Chrysler" barrel head and saw-mill at Windham Centre on May 27.

Niagara Falls Power: Its Importance as an Industrial Factor *

By F. J. Tone **

In twenty years, the electric furnace has rendered possible an industrial advance rivalling the progress of the preceding two hundred years. The almost magical properties possessed by electric products are only equalled by their variety and number, while their industrial value is amply demonstrated by their ability to reduce costs of other materials and products.

THE development of Niagara power in 1895, only 20 years ago, marks the beginning of the electric furnace art. It stands to-day as one of the big factors in our industrial life. Up to 1895, when Charles M. Hall came to Niagara, the aluminum industry depending on steam power had given little promise of commercial success. Its almost incredible development during 20 years has been due to the impetus of Niagara power, and its future magnitude no one dares to predict. Dr. E. G. Acheson with a 150-h.p. furnace operated by electric power generated from steam had made a commercial failure of carborundum. Coming to Niagara in 1895, he was at once enabled to found the artificial abrasive industry. Willson, the inventor of calcium carbide, was working at Spray, N.C., with a 200-h.p. furnace. To-day we have 12,000 to 15,000-h.p. furnaces making almost as much carbide in one day as the former furnace produced in a year.

With the technology of these great industries, aluminum, calcium carbide, cyanamid, abrasives, ferroalloys, silicon and graphite we are all familiar, but few realize their economic importance or to what an extent the industrial and metallurgical arts are indebted to Niagara power for their development, especially at this time, when we are taking stock of our industrial assets and determining how the nation can best make itself industrially self-contained.

Ferrosilicon

The manufacture of steel is the greatest of all American industries, and its dependence on Niagara power is strikingly illustrated by a study of the ferroalloy industry. In 1915 the estimated production of finished steel in the United States was 28,000,000 tons, and in a major portion of this there was employed as the chief deoxidizing agent high-grade electrically produced ferrosilicon. This alloy is used in practically all steel manufactured by the basic open-hearth process, which in recent years has so far supplanted the Bessemer process as to account for more than 70 per cent. of the total production. To a lesser extent electrically produced ferrosilicon is used in almost all the other processes of steel manufacturing.

The steel-casting industry finds high-grade ferrosilicon practically indispensable for eliminating blow-holes and producing sound castings. The cast-iron foundry industry has in recent years realized the advantages of the use of this alloy, and progressive establishments now depend on it for a control of their castings.

Niagara Falls is the home of ferrosilicon in the United States, and up to the present time the total domestic production has been made from Niagara power. For a short time prior to the European war some ferrosilicon was imported, but a large portion of this was produced by Niagara Falls power in Canada. The Canadian producer has, since the war began, been compelled by Government order to export ferrosilicon to countries other than the United States, thus increasing an existing unprecedented demand for the domestic product and causing a power famine on the American side of the Niagara River.

This fact has a significant bearing, not only on the inadequacy of the total supply of Niagara Falls power, but on the regulations which govern the importation of electrical energy into the United States. A cessation of the supply of ferrosilicon would be nothing short of a calamity to the steel business, and when we further consider that specifications for shell steel for munition purposes call for 0.20 to 0.30 per cent. silicon, we see the role ferrosilicon plays in munition manufacture and the realization of our own programme of preparedness.

Ferrochromium

The essential element in the manufacture of successful armor-plate and armor-piercing projectiles is introduced into steel by ferrochromium. Without this alloy not a battleship could be provided with protective armor, nor a coast defence gun served with modern projectiles. More than one-half of that now consumed in the United States is produced at Niagara Falls. Ferrochromium likewise enters into the manufacture of automobile steels, steels for jaws, balls, linings of crushing machinery, dies and a variety of special steels.

Sir Robert Hadfield has compared the striking energy of an armor-piercing projectile with that of a modern express train. He states that a 14-in. (35 cm.) projectile weighing 0.62 ton and fired so as to pierce 12-in. (30 cm.) armor plate at a distance of eight miles (13 km.) must have a striking energy of 30,000 foot tons (9,000 m. tons) and a striking velocity of 1,700 ft. (510 m.) per second, or twice the energy of a modern express train running at 40 miles (67 km.) per hour. The shell has 1/8000 the bulk of the train, and the metallurgist has been able to provide a shell having a steel point of such quality that it delivers this concentrated energy upon the hard-faced plate and passes through it without suffering deformation. This is a striking metallurgical achievement, but it is the electric furnace and ferrochromium that have made it possible.

Tungsten-Vanadium-Molybdenum

These alloys are made in part from Niagara power, and when made elsewhere there is largely used as a reducing agent metallic aluminum, also a Niagara product. They form the chief constituents of a relatively high-priced group of products representing an annual production of several millions of dollars, and which in conjunction with chromium are absolutely necessary in the manufacture of high-speed tool-steel, magnet-steel, certain gun-steels, and a variety of special steels. High-speed steel furnishes a most striking example of the dependence of the metal-cutting industries on products of Niagara power. To one familiar with machine-shop practice under the limitations of carbon steel, where it was necessary to maintain a cool cutting edge, it is amazing to see a 17-in. (43 cm.) forged shaft destined for some battleship revolving at a surface speed of 30 ft. (9 m.) per minute, the tool of high-speed steel working at red heat, and chips 1½ in. (4 cm.) wide and ⅝ in. (1.4 cm.) thick coming off, colored a deep blue. Ferrochrome and the other alloys of this group have made this possible. High-speed steel has tripled the capacity of every machine shop in the world and the efficiency of every workman. It has cut to one-third the capital invested in tools to accomplish a given volume of work.

Considering the metals or alloys of chromium, tungsten, vanadium and molybdenum as a group, it may be positively stated that in the absence of these products we should not be in a position to build modern battleships, guns, submarines and many other machines necessary for the nation's defence, to proceed with thousands of operations involving the cutting of metals at a rate comparable with the present or necessary to

*From a paper read before the spring meeting of the American Electro-Chemical Society at Washington, D.C.

**Works Manager, Carborundum Co., Niagara Falls, N.Y.

successfully meet foreign competition. A goodly proportion of our steel and metal working industries, mining operations and scores of other industries would find themselves in the condition of practically twenty years ago.

Ferrotitanium and Silicon Metal

Titanium, as a ferrocarbon-titanium alloy, is employed in a large tonnage of steel made by the Bessemer and open-hearth processes, as well as in the production of steel and iron castings. The aluminum bronze and other nonferrous alloy industries are being greatly benefited by the use of titanium alloys.

A special steel of great importance to electrical industry is silicon steel, used in electrical transformer construction and all alternating-current apparatus. Silicon metal and 75 per cent. ferro-silicon essential in its manufacture are produced only at Niagara Falls. The ageing of transformer steel has long been the cause of a serious falling off in efficiency. This loss often doubled after a few years' use. Silicon steel does not age. Moreover, its original hysteresis loss is 25 per cent. less than that of the old type of steel. The saving in a large generating and distributing system from the generator through step-up and step-down transformers to the motor may be as high as 6 per cent. Thus silicon steel, a comparatively unknown product, is saving many millions of dollars annually wherever electric energy is transformed.

Silicon metal as a "preparedness" product is important in the generation of hydrogen for aeronautical purposes. In conjunction with caustic soda it forms the cheapest method of generating hydrogen in the field or on shipboard when portable outfits are required.

Aluminum and Abrasives

The manufacture of aluminum is the largest of the electro-chemical industries in point of power consumed and value of product. Commercial development was made possible by Niagara power, and Niagara Falls was for many years the only seat of the industry. Even with the prodigious increase in production the scarcity of aluminum is to-day very acute and is regarded by automobile engineers as little less than a calamity.

The electric furnace abrasives, carborundum and alundum, are fundamental elements in the metal-working industries. They have revolutionized the methods of finishing machine parts, just as high-speed steel has revolutionized the art of shaping metals by cutting. Artificial abrasives have been gradually displacing natural emery and corundum, until in 1914 they constituted 62 per cent. of the total abrasives used in the United States. The natural abrasives have practically all been imported, and comprise Turkish and Grecian emery. With the beginning of the war mining in Greece and Turkey ceased, and artificial abrasives have been called on to supply the whole field. There are five plants making artificial abrasives from Niagara power, three of which are on the American and two on the Canadian side of the river.

The great metal-making industries making agricultural implements, locomotives, cash registers, electrical machinery, firearms, flour-milling machinery, paper machines, automobiles and all castings of steel, iron and brass are entirely dependent to-day for an adequate supply of grinding materials on Niagara power. As a simple example, take the automobile industry. The mechanical perfection of the modern automobile and the interchangeability of parts have been made possible only by the development of the grinding machine and the grinding wheel.

Cut off the artificial abrasives and force the automobile manufacturer to go back to the grindstone, at the same time eliminating the other products of Niagara power, aluminum, high-speed steel and special steels, and we would see a works which now produces 500 cars per day reduced to an output of considerably less than 100 cars, with the same force of workmen and the same plant equipment. This would mean such an increase in price that there would be no automobile industry on its present existing lines.

Manganese steel, one of the unique materials of engineering, was little known fifteen years ago. To-day the output in frogs and switches, burglar-proof safes, dredges, gears and rolls represents many millions of dollars. No steel tool will cut it. Without grinding wheels to shape and fashion manganese steel it would still be a metallurgical curiosity.

Calcium Carbide and Artificial Graphite

This electric furnace product is the only commercial source of acetylene, important in its application to the oxy-acetylene cutting and welding of metals. A cessation in the domestic production of calcium carbide would entail enormous loss.

Calcium carbide is also the material from which is produced calcium cyanamid, a most important compound to-day in the field of fixation of atmospheric nitrogen.

Artificial graphite is an electric furnace industry that owes its inception and entire development to Niagara power. The production, which totals several thousand tons annually, falls in two general classes, electrodes and powdered graphite.

Graphite electrodes are used exclusively as anodes in all electrolytic cells for the production of caustic and chlorine. They are a fundamental requisite of this vast industry. With the supply of plantinum cut off they are now replacing this expensive metal as anodes in the electrolytic chlorate processes. Graphite electrodes are extensively used in electric, smelting and refining furnaces, producing high-grade steel, alloy-steels, ferroalloys, copper, zinc and nickel.

All the manufactured graphite used in the world is produced at Niagara Falls. It occupies a field of its own, which cannot be filled by natural graphite, and it is another striking illustration of the electric furnace "going nature one better."

Thus we see that the electric furnace is not merely a new metallurgical tool, but an important element in our economic life. When future generations begin to shiver for want of coal and to starve for want of nitrogen, the present generation will be remembered not as champions of the preservation of scenic beauty, but as champions of the ugliness of wasted resources.

THE CRUCIBLE SITUATION

THE crucible manufacturers have been put to sore straights for the past eighteen months in the securing of their raw materials. First came the embargo on Ceylon plumbago—(this being lifted after a few months) which left the market in a depleted condition. The natural result was a tremendous advance in price. Next came the exhaustion of the foreign clay, which is used in crucible making, as a binder. The clay used, as far back as crucible history in this country goes, has come from the little principality of Klingenburg in the Black Forest in Bavaria, where, so the story goes, the entire government expenses are paid out of the export duties collected from the clays shipped out. This Klingenburg clay has for years past, been the only clay the crucible makers seemed to think they could satisfactorily use. No shipments of this clay have been made since the beginning of 1915.

Some makers have husbanded the enormous supplies of the foreign clay which they had on hand when hostilities started. This husbanding the stock of the now almost priceless raw material, has been done by partially substituting clays from various parts of the United States, and mixing with the Klingenburg clay.

The tests and trials made by the crucible makers during the past twelve months have been almost endless. When one takes into consideration that it takes from six to ten weeks to prepare a graphite crucible for service in the foundry, some slight idea can be formed of what the crucible maker has to contend with. Added to this delay, and before he can even start in on these goods that will not be remarkable for two months to come, the chemists' laboratory tests and trials must be made. These

have run into the thousands. Then must come the practical tests in a small way in the foundry; for the crucible maker would stare bankruptcy in the face, if he continued making up hundreds of thousands of dollars worth of goods out of Ceylon plumbago, costing from seventeen and a half to twenty-five cents per pound, only to find at the end of two or three months that they might not be of service to the user.

The bright side, however, to all that, is that in many cases the crucibles made with American clays have gone a surprisingly long time in the fires. In one case there is a report on a No. 300, which ran forty heats on manganese bronze, and dozen of cases as high as thirty-eight and forty heats on No. 100's melting car box metal. The annoyances now seem to be the ununiformity of the products secured. Crucibles made by the same potter, out of similar materials, at the same time, and burnt in the same kiln, when run by one melter on same grade of metals, rise and fall to a variation that is a shock to both user and maker.

All this will in time be rectified. As soon as the manufacturer has become more familiar with the mixing and blending of our native clays, they will no doubt be able to produce in time a crucible as satisfactory as or superior to those manufactured heretofore. The user, however, must use more care in handling the American clay crucibles. It is imperative that these crucibles be thoroughly dry and warm before going into the fire, and that they are heated up very slowly on the initial heat. Some users make a little fire with charcoal inside the crucible, and others put hot ashes in, before placing the pot in the fire, so that the crucible is hot when it goes into the fire for the first heat. There are certain advantages in heating the crucible from the inside first rather than the outside. He must be very careful in the matter of wedging, as American clays have not the same tensile strength when hot, as foreign clay.

The advance in prices of crucibles is due to the unusually high price of Ceylon plumbago just at present, just as with zinc, copper, aluminum, lead, etc., but as soon as the war insurances are a thing of the past, then plumbago will be at a normal figure once more, and crucibles will again be marketed at as low or lower prices than they have been for many years past.

ONTARIO BUREAU OF MINES REPORT

THE demand for nickel and copper, due to the war, has been insatiable, and the Sudbury mines have shown a capacity for meeting the requirements which could scarcely have been anticipated. Such is the statement made in the report of the Provincial Bureau of Mines for the first three months of 1916. The output of nickel and copper in the matte was fifty per cent., greater than in the first three months of 1915. If the present rate of production is maintained through the year, 1916 will see about 40,000 tons of nickel and 22,000 tons of copper turned out by the smelters in the Sudbury district, as against 34,000 tons of nickel and 19,600 tons of copper in 1915. The Canadian Copper Co. and the Mond Nickel Co. are the producers; the Alexo Mine turning out a small quantity of ore, which is sold to the Mond Co."

Cobalt oxide and nickel oxide met with a rather better demand, though the quantities exported are still below those of normal times. Metallic cobalt is coming into use principally in steel alloys, and there is now a small quantity of nickel refined in Ontario from the silver cobalt ores of the Cobalt camp. Taking the figures as a whole, there are increases in all products except iron ore.

The total value of the production for the first three months of 1916 was $14,276,382, as compared with $9,358,210 for the corresponding period of last year. This large increase was due not only to the greater output but to the higher prices now prevailing for most of the metals.

Increase in Gold Yield

The increase in the yield of gold was 31,511 ounces, worth $656,872. Compared with the rate of production for the whole of last year the advance was less marked, but developments now under way are likely to lead to a substantial increase. Porcupine provided the bulk of the 107,818 ounces production, namely, 99 282 ounces. Hollinger led in output, followed by Dome, Acme, McIntyre-Porcupine, Porcupine Crown, Vipond, Schumacher and Dome Lake in descending order. The mines situate elsewhere making up the remainder of the yield are Tough-Oakes and Croesus. Consolidation of the Hollinger, Acme and Millerton interests, says the report, will no doubt lead to a more extensive development and a greater output from these properties.

Silver Yield

A feature of the quarter was an actual increase in the yield of silver as compared with the first three months of 1915, amounting to 67,664 ounces, from 5,230,167 to 5,297,831. In value the increase was proportionately greater namely $462,673. This was due to the remarkable rise in the price of silver, amounting to about 50 per cent. over the average figure for 1915. A large part of this increase took place in the latter part of the quarter and afterwards, consequently the benefit of the higher prices was only partially realized during the three months

The natural effect of the advance has been to stimulate both mining and prospecting in Cobalt and to enable low-grade ores in the mines or on the dumps to be worked, which at the former low prices of silver were without value. Nipissing continues to lead in quantity of output. Townsite-City, Seneca Superior, Kerr Lake, La Rose, Coniagas, Cobalt Lake, McKinley-Darragh-Savage, Beaver, etc., follow in the order named.

The blast furnaces of the Province produced about 70 per cent. more pig iron than they did in the first quarter of 1915, and the produce was worth almost 100 per cent. more. About 15 per cent. of the iron ore charged into the furnaces was taken from deposits in Ontario, the remainder coming from the United States.

CANADIAN OVERSEAS RAILWAY CONSTRUCTION CORPS

POWERFUL steam shovels, weighing sixty-five tons each, capable of eating up the earth at the rate of 150 to 200 cubic yards an hour, and self-propelling extension track pile drivers, are part of the equipment recently purchased by the Government for Col. C. W. P. Ramsay, of the Canadian Overseas Railway Construction Corps. This plant was selected by Col. Ramsay's colleagues in the Engineering Department of the Canadian Pacific Railway, and is being prepared by that company at the request of the Government for shipment abroad.

The Canadian Overseas Railway Construction Corps has already built many miles of track at strategic points, and is all the while engaged in surveys for further construction. The work has often to be done under fire, and though there have been many narrow escapes, there have been no serious casualties. Out of the non-commissioned officers and sappers that enlisted on the foundation of the Corps 18 have already received commissions in the Royal Engineers, a remarkable tribute to their efficiency, while Col. Ramsay and Major Harvey have been mentioned in despatches. The splendid work of these Canadian engineers has, we understand, been highly appreciated.

THE life of belting is chiefly dependent on:—1—the "total load" to which it is subjected: 2—how the belt is joined: 3—the speed at which it runs; 4—the care bestowed upon it: 5—whether it is kept free of mineral oils.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

BIG GUNS AND PROJECTILES

At a meeting of the Faraday Society of Great Britain recently, Dr. Rosenhain delivered his cinematograph lecture on "The Making of a Big Gun." Sir Robert Hadfield, the president, was in the chair, and in introducing the lecturer he gave a few historical notes which are of more than ordinary interest at the present time. After alluding to the fact that Hadfields had made a special study of projectiles for more than a generation, he mentioned that he had seen guns up to 16 in. calibre fired at various proving grounds, both private and Government, including Shoeburyness, Portsmouth, Gavers, Le Creusot, Sandy Hook, Indian Head, Ochta, Meppen, Magdeburg, and elsewhere, and had studied results of tests at foreign proving grounds, at Spezia (Italy) and Kure (Japan).

The largest gun he had seen fired was the 16 in., weighing about 120 tons and being 35 calibres in length. There was at the time only one gun in existence of this calibre, namely, at Sandy Hook. The shot weighed 2,400 lb. On one occasion the range attained was 21 miles. The round he saw was fired at a comparatively low velocity, about 1,400 foot-seconds, and was directed against a 12 in. hard-faced armor plate, inclined about 45 deg. Hence the blow was more of a glancing than an impact one, and the plate was cracked but not perforated. He witnessed the round about a quarter of a mile from the gun, and was able to observe the fragments as they ricochetted out to sea over a distance of about 1¼ miles. The gun was designed for coast defence purposes, and he believed a number of similar pieces had been made for the Panama defence scheme.

Internal Pressure Feature

Continuing, Sir Robert said that it must be borne in mind that, usually, when big calibre guns are referred to in the daily press, such as the 42 cm., they are really howitzers. In artillery parlance, a howitzer is not considered to be exactly a "gun." Its internal pressure very seldom exceeds 14 or 15 tons per square inch, and is generally not so much as that, whereas a real gun, such as is used in the navy or for coast batteries, has to stand a pressure of 20 tons per square inch.

J. A. Longridge, in his excellent series of papers given before the Institution of Civil Engineers between 1879 and 1884 on "Wire Gun Construction" and "The Construction of Heavy Ordnance," and also in his book "The Artillery of the Future" and the "New Powders," published in 1891, said that it would some day be possible—in fact, at the time of making the statement he said that he was prepared to do it—to make guns to stand up to 30 tons pressure. Sir Robert wondered why this subject had not been followed up.

As regards our own service, it is, he said, well known that we have 13.5 in. and 15 in. guns of the highest possible quality. The results obtained reflect great credit upon the British artillery engineer and the metallurgist, who by their combined efforts have produced guns giving, as they have done, splendid results, in fact, no fault has been found with them in service. They are wire-wound, and he thought it might be of interest to state—and it was an open secret—that a certain foreign nation about two years before the war broke out, desiring to order big naval guns, sent a commission to visit the various big gun-making centres of the world, and this commission unanimously reported that the British wire-wound gun was the best which could be produced.

Muzzle Energy Feature

Whatever the future has in store in the way of developments of the power of such guns, whether by means of increased calibre or by constructing calibres such as now made to stand higher pressure, he was quite sure that the British artillery engineer and the metallurgist would continue to hold the proud position they at present occupy of building the most powerful guns the world has yet produced; that is to say, the muzzle energy of British guns outranks that of the guns of any other nation. The 16 in. American gun to which he had previously made reference, whilst not of the howitzer type, had nothing like so great a muzzle energy as, for example, our 15 in. naval gun, and the so-called big German guns, about which there had been so much talk in the papers, are as regards their muzzle energy very small and inferior weapons in comparison with ours. With some of our naval guns it would be quite possible to send a shell over Mont Blanc.

Modern Gun a Heat Engine

The modern gun, said Sir Robert, is really a heat engine, and a few of the feats which I myself personally have been in touch with—that is, the results obtained from what may be termed the modern high-speed and great-power engine known as the gun, may be of interest. For example, I well remember many years ago at Shoeburyness a 9.2 in. armour-piercing shell being fired through a 9 in. armor plate known as "compound," that is, of combined iron and steel. The shot perforated the plate and backing, got out of the sand butt, and was recovered whole, and alongside it, to the general surprise, was found a small rabbit. A big gun for little game!

Another instance I well remember. A 9 in. wrought iron plate was being attacked by a 9.2 in. Whitworth shot. This plate was swung upon trunnions projecting from either side. In other words, before firing it would have been possible with comparatively little energy to make the plate swing backwards and forwards. When the Whitworth shot was fired against this plate and perforated it, the plate was lifted from its trunnion seating and thrown away some 10 feet, or 12 feet, yet the hole was properly punched in the plate. That is to say, before the plate had time to swing the shot passed through it. This brings home a fact which is perhaps not sometimes realized, namely, the enormously rapid action of the shot in perforating. For example, a 15 in. shot going through a 15 in. plate would perforate it in about one-thousandth part of a second—probably in even less time. It will be understood, then, what tremendous stresses are suddenly brought to bear upon the shot, and how the slightest flaw or imperfection of any kind will wreck it.

Another instance may be mentioned. This refers to old experiments, but nevertheless is interesting. One of our 6 in. shot was fired against a 9 in. compound plate and recovered unbroken. It was so little injured that it was put in the gun and fired again. A second 9 in. plate was also perforated, the shot being recovered unbroken but slightly ground. It was fired a third time against a hard-faced plate, and being uncapped, of course broke. This illustrates how well a shot properly hardened and tempered can resist the enormous complex stresses suddenly brought to bear. In other words, the shot by means of its quality, and when possessing enough energy, is thoroughly master of its work against any type of plate without a hard face.

To overcome the hard face the modern cap has been introduced. This enables even the hardest face to be perforated. It is curious to find that caps have to

swell to the full diameter; in other words, the shot has to pass through the cap. The cap is not merely dispersed as might be expected. The action is, however, very sudden and the soft metal of the cap expands, so that it is really punched; the expansion or elongation of the mild steel taking place so quickly that it does not break until practically the full diameter of the shot has been reached. It is no doubt owing to this fact and to the radial inertia of the cap itself that a modern cap is enabled so completely to protect the shot that the latter then passes unbroken through the armor plate attacked; that is, before the face of the plate is reached, certain support is afforded long enough to the point of the shot to give it time to transfer some of its energy to the plate attacked. We are indebted to the Engineer for the foregoing.

SHELL MACHINING EQUIPMENT—II.

IN our May 18 issue, equipment for 4.5 in. high explosive shell manufacture, covering boring and turning lathes, thread milling and waving machines, chucks, etc., together with operation features, were discussed as far as the shell nose machining procedure. The latter constitutes the substance of what follows.

Nose Piece Machining

The machinery of the shell body thus has devoted to it twenty of the lathes in the whole plant. The remaining seven lathes are devoted to the machining of the nose piece. The first operation is to cut off suitably sized pieces from stock bars. For this, one machine of the turning lathe type is used. The second operation is to bore and taper such cut-off piece. Two machines of the boring class are given over to this operation. The chuck used grips the work at three points, two of these being flat key-like strips and the third a set screw.

The third operation on the nose piece consists of forming it roughly to the required curvature—roughly because its finished shape is given it under operation sixteen on the shell body. One tool of the turning lathe type is employed for this stage of the work. A plate having a coned central boss is bolted to the end of the hollow spindle of the lathe. The usual pull-up passes through the coned boss, and at its end is provided with a nut and a U-shaped washer. With the pull-up rod slackened a little, the U-shaped washer can be removed and the work pulled off the conical boss and over the nut on the end of the rod. The point of the tool is induced to follow the required curve by connecting the tool slide to a radius link, which at the other end is pivoted to a cast iron bracket bolted to the side of the lathe. The tool slide is otherwise free to move on the saddle cross guides. Hence, as the saddle is fed towards the work the tool point moves towards the operator, so generating the required curve.

As actually carried out, the tool slide is in two parts, one carrying the tool post and the other the pivot pin for the radius bar. A threaded spindle passing through a nut in the former part and fitted at its end to the latter joins the two. By rotating this spindle the tool can be drawn in or pushed away from the pivot pin, so permitting the depth of cut taken to be varied.

The cut in the above operation is not carried right to the end of the nose piece, for in the next stage this end is turned down parallel to receive the thread whereby the nose piece is fixed to the shell. For this operation one lathe of the turning type is set apart. A recessed plate is bolted to the hollow spindle end, and through the boss of this plate there passes a bolt which at one end is threaded over the pull-up rod and at the other is provided with a conical plug—not U-shaped—and a nut. The nut and plug have to be removed to unchuck the work. The nut thread fits the end of its bolt loosely, and the nut is locked tightly when chucking a piece by the pull-up rod. The whole chucking operation, we understand, occupies not more than fifteen to twenty seconds.

The fifth operation on the nose piece is the milling of the thread on the turned down portion left by the previous operation. For this one thread-miller is employed. The method of holding the work is identical with that used in operation four.

In operation six the nose piece is turned about and the parallel bore milled for the fuse thread. One thread-miller is provided for this. A plain tapped plate is bolted to the hollow spindle end. The thread in this is a loose fit for the external thread on the nose piece. The pull-up rod carries a piston-like member provided with a conical nose or boss which, when pressed into the conical bore of the work, steadies and locks it. Cuts and data, courtesy The Engineer, London, England.

CANADIAN GOVERNMENT TELESCOPE COMPLETED

THE work of two and one-half years by the Warner & Swasey Co., Cleveland, Ohio, the largest reflecting telescope in the world, was put on exhibition at the company's plant last week. Scientists of international reputation from all parts were present.

The telescope is for the Dominion Astronomical Observatory being completed near Victoria, B.C., by the Canadian Government.

This telescope is to be used principally for measuring velocity of the fainter stars, either toward or from the earth. With this instrument it will be possible to expose the most sensitive of photographic plates for five or six hours and in this manner gather details about some of the stars that have hitherto been inaccessible.

The 72-inch reflector in the instrument makes possible the additional research. The fact that it collects nearly 50 per cent. more light than any other reflector adds to the photographic possibilities. The telescope is of the type scientifically known as equatorial, swinging on a polar axis which parallels the earth's axis. The instrument weighs fifty-five tons and will rest on massive piers reaching to bed rock.

In spite of the enormous weight the instrument is so delicately balanced and has such smoothly working bearings that an electric current sufficient to burn an ordinary incandescent light will control it. A luncheon was given by the company officials in honor of Dr. Plaskett, Ottawa, head of the new observatory, at the Union Club. Noted scientific men present were:

Dr. John A. Brashear, Pittsburg, ex-chancellor of the University of Pittsburg; Dr. Charles S. Hastings, Yale University; James B. McDowell, of the John A. Brashear Co., Pittsburg; Alexander Duval, of National Optical Glass Co., Washington, Pa.; Dr. W. J. Hussey, director of Detroit Observatory, University of Michigan, Ann Arbor; Dr. R. H. Curtis, astronomer, University of Michigan, and E. D. Pearce, Providence Institution for Savings, Providence, R.I.

Among prominent Clevelanders present were:

Ambrose Swasey, Worcester R. Warner, William D. B. Alexander, Elbert H. Baker, Major P. S. Bond, Charles F. Brush, Edward P. Burrell, A. C. Cook, George A. Decker, F. H. Ginn, Dr. E. P. Hyde, Francis F. Prentiss, Frank A. Scott, Warner Seely, Leslie B. Stauffer, Lyman H. Treadway and Samuel T. Wellman.

"More Oil" Signal.—Near our plant, says an exchange writer, is a mill in which there is a central oiling system, the main oiler in the engine room holding about 15 gallons. As long as the mill engine is in motion the pump forces oil through all the small pipes to the gun feeds, niggers, trips and transfers; but with all the oil that is used, and with an engineer in constant attendance, with an oiler whose duty alone it is to see that oil is passing in all the sights to each appliance being supplied, it is a regular thing to hear each day the signal whistle from the various machines for "more oil." What is wrong?

PROGRESS IN NEW EQUIPMENT

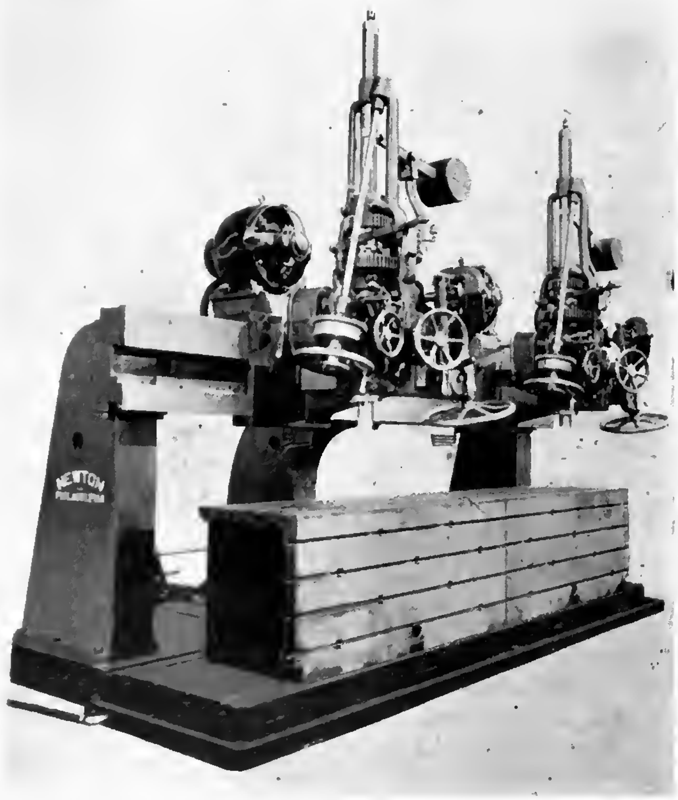
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

TWO-SPINDLE FRAME DRILLING MACHINE

THE accompanying photograph illustrates a new design of drilling machine having sufficient range and flexibility of operation to handle all the parts necessary in the construction of locomotives from the smallest to the largest in addition to being particularly adapted to drilling locomotive frames.

The spindles of the machine are 4 in. in diameter, have an automatic geared feed of 18 in. and a vertical adjustment of 18 in. through direct connected gearing for the fast hand traverse and through a friction clutched worm and worm wheel for the hand slow adjustment. There are provided four changes of friction clutched geared feed ranging as follows:—.0078 in., .0126 in., and .0156 in. and .0185 in. per revolution of spindle. The range of the spindle speeds is from 28 to 456 r.p.m.

The drive to the spindles is by individual 10 h.p. motors running at from 300 to 1,200 r.p.m. motion being transmitted through the horizontal driving shaft on which is mounted a double train of bevel clutched gears and further through the vertical shaft on which the back gears are mounted, giving two changes of speed in addition to the range of the motor.

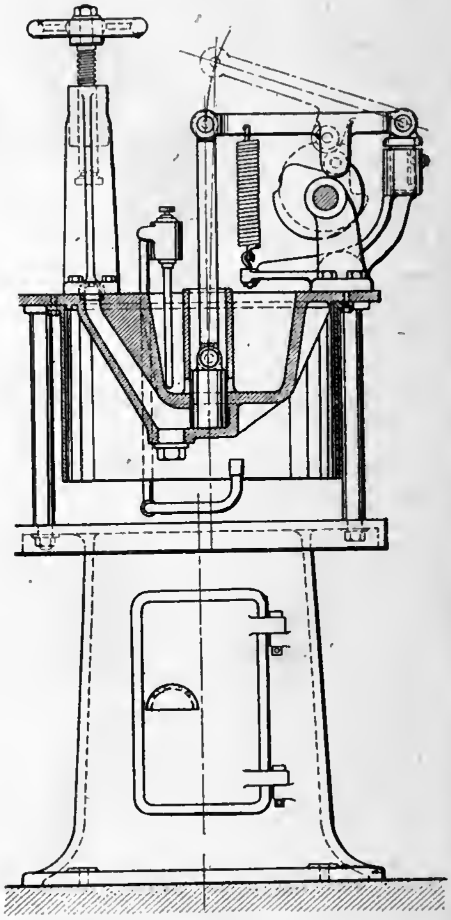


TWO-SPINDLE FRAME DRILLING MACHINE.

The spindle is counterweighted and is provided with a roller thrust bearing at the bottom of the rack sleeve. A No. 5 Morse taper is provided with retaining and drift key holes. Reversing fast traverse is provided to the saddles on the rail from a minimum distance between centres of spindles of 48 in. to maximum distance of 15 ft. hand horizontal adjustment to the saddles being obtained by the hand wheel shown at the bottom of the arm.

The gears controlling the feed are mounted in a box, the different combinations being engaged by a spring key controlled by the small hand levers shown. There is also provided lateral hand adjustment to the spindle saddle on the arm from a minimum distance of 6 in. to a maximum distance of 24 in. from the face of the cross rail. The arm has two bearings on top of the cross rail made removable for renewals and has square lock gibbed bearings cast solid with brass taper shoes to compensate for wear.

The motor bracket is cast solid with the arm giving a very rigid construction necessary for continued service under the enormous strains to which these machines subjected when using modern



DIE-CASTING MACHINE. ELEVATION.

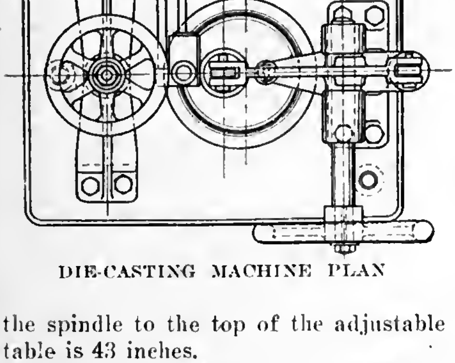
high speed drills. The cross rail is of the box type construction of very heavy section further supported by ribs. The machine is furnished with two adjustable work tables 30 in. wide by 36 in. high by 7 ft. 6 in. long, each of box type construction, having vertical and horizontal working surfaces substantial tee slots having been provided for the work.

The machine has a floor plate the front of which forms a tee-slotted work table, entirely surrounded by an oil pan for catching the lubricant and the remainder supporting three heavy uprights for holding the cross rail.

Screws are provided for adjusting the work tables, through individual 5 h.p. motors, permitting of simultaneous or independent power hand adjustment to the work tables. Pump piping and attachments are also provided.

The maximum distance from the floor plate to the bottom of spindle is 81 in.,

the maximum distance from the end of the spindle to the top of the adjustable work table is 48 in. and the minimum distance from the top of floor plate to the bottom of the spindle is 64 in. and the minimum distance from the end of



DIE-CASTING MACHINE PLAN

the spindle to the top of the adjustable table is 43 inches.

The Newton Machine Tool, Works, Inc., Philadelphia, are the builders of this machine.

NEW DIE-CASTING MACHINE

AN interesting design of die-casting machine has been recently patented and placed on the market by the Monometer Manufacturing Co., Birmingham, Eng., who have constructed it with a special view to the use of aluminum and its alloys, while giving equally as good results with other metal alloys.

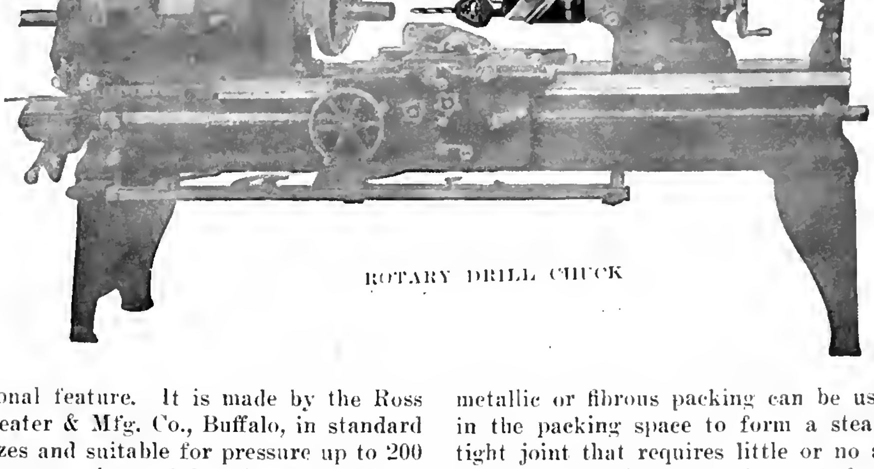
The apparatus consists of a gas-fired melting pot with suitable extruding mechanism and die clamp mounted on a cabinet base as shown in elevation and in the illustration. The melting pot; shown in section, is provided with a hollow cylinder extending upwards from the centre of the bottom, port holes on the sides allowing metal from the pot to enter the cylinder when the piston is elevated, and an inclined passage connecting the lower end of cylinder with the die clamped in place on top of discharge orifice.

The movement of the piston is controlled by a hand operated cam-shaft which elevates the rocking lever to the position shown by the dotted lines thus causing the piston to rise past the ports and allow the metal to enter the passages. The cam is of such a shape that the piston is raised slowly and then returned with a sudden drop due to the pull of the spring on the rocking lever, it being claimed that the rapid injection of the metal produces very sound and homogeneous castings.

The pot is made of metal of a special composition which resists the action of molten aluminum, while the gas supply to the burners is controlled by thermostatic device which automatically controls the temperature at a given point.

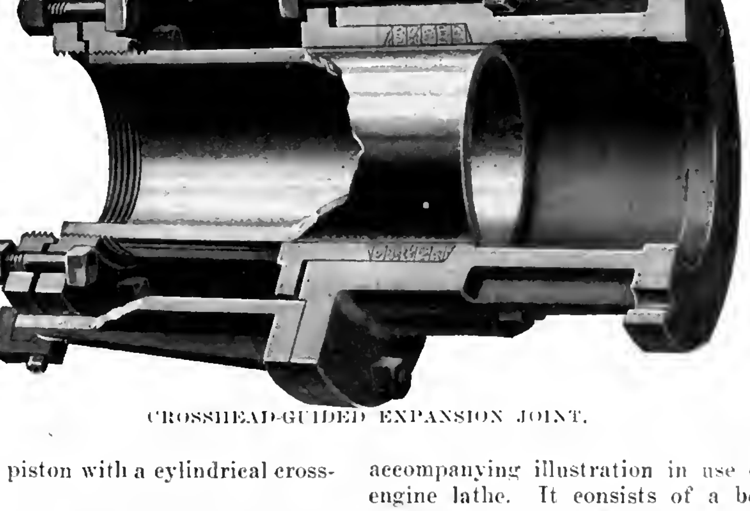
CROSSHEAD-GUIDED EXPANSION JOINT

THE accompanying illustration shows a sectional view of the Ross crosshead-guided expansion joint, which is so named because of a prominent constructional feature. It is made by the Ross Heater & Mfg. Co., Buffalo, in standard sizes and suitable for pressure up to 200 lb. per sq. in., and for pipes up to 24 in. diameter.



ROTARY DRILL CHUCK

The joint is formed of two members which slide one within the other, the outer one being made in two parts, which are bolted together at the outside circumferential joint near the centre, while the inner member is composed of a sleeve, one end of which passes through the gland and stuffing box formed in one part of the outer member, while the other end is supported by companion flanges as shown. These flanges are accurately machined on the diameter so as to slide smoothly and freely in the bore of the outer member or guide, the action of the inner member being precisely that of a trunk piston with a cylindrical crosshead.



CROSSHEAD-GUIDED EXPANSION JOINT.

The desirable support thus given to the crosshead flanges keeps the sleeve in proper alignment with the outer member, and prevents sagging strains from destroying the packing and causing other excessive tear and wear. Access to the stuffing box is readily obtained by removing the bolts on the guide flange and sliding the casing back. Any kind of metallic or fibrous packing can be used in the packing space to form a steam-tight joint that requires little or no attention. Occasional drawing up of the packing gland can be done from the outside by means of the long bolts shown.

As the inner area of the slipping section is equal to the area of the pipe, a state of balance is obtained in the joint which relieves the stress that would otherwise occur. Joints intended for use at points where elbows or tees for branch lines are located have anchorage footings cast on to give the required support to vertical pipes and fittings.

MULTIPLE ROTARY CHUCK

AN appliance which the makers term a Multiple Rotary Chuck is shown in the accompanying illustration in use on an engine lathe. It consists of a bearing bracket, which is clamped to the tail-stock spindle, and carries a revolving turret holding five tools, which are

brought into operation as required and locked accurately in position. For suitable classes of work this enables a lathe to be quickly converted in a turret lathe on which drilling, tapping, counterboring, reaming, etc., can be performed without loss of time in changing tools.

The device is of substantial construction, being capable of drilling up to $1\frac{1}{2}$ in. dia. hole, and weighs 27 lbs. It is built by the Newman Mfg. Co., Cincinnati, O.

ROYAL CANADIAN INSTITUTE BUREAU OF SCIENTIFIC AND INDUSTRIAL RESEARCH

A BUREAU of Scientific and Industrial Research has been founded by the Royal Canadian Institute, Toronto, to carry on work in Canada on the same lines as that now carried on by the Mellon Institute of Pittsburg, Pa., and other like institutions in the United States and elsewhere. The Royal Canadian Institute is particularly fortunate in having for its president, during the formative stages of this bureau, Dr. John Cunningham McLennan, B.A., Ph.D., F. A. A. S., F. R. S. C., F. R. S., Professor of Physics and director of the Physical Laboratory, at the University of Toronto.

Associated with Dr. McLennan in the work, and as vice-presidents of the Royal Canadian Institute, are John Murray Clarke, K.C., who is well known throughout the country as a progressive leader and author, and Dr. Alexander Charles McKay, principal of the Central Technical School, Toronto, whose great object in life is the up-building of industrial education, in which sphere he has already attained marked success. The work has also the support and co-operation of a number of other prominent men, including three Fellows of the Royal Society.

Co-operation of Industry and Learning

The idea of the fellowship system in the application of science to industry was first thought out by the late Dr. Robert Kennedy Duncan, a distinguished graduate of the University of Toronto, the first director of the Mellon Institute, Pittsburg, after prolonged visits in Europe during 1904 and 1907. Through his visits to workshops, laboratories and universities of most of the principal countries of Europe, and through his talks with industrialists, Dr. Duncan became impressed with the spirit of co-operation which existed abroad between industry and learning, and which made for the advancement of both. The industrial fellowship system occurred to him as a sane, practical scheme of relationship between industry and learning, which would promote the efficiency of American industry.

Research Procedure

When a problem is assigned to the Institute, the director selects, after careful inquiry, the best available man who can be found for this particular work. The fellow, as this man is called, is one who has invariably pursued post-graduate work in a special field, and has shown a gift for research. This man, if the fellowship has been given by an operating concern, first spends sufficient time in the factory of the donor to become acquainted with the problem at first hand. In this way he gains a knowledge of the manufacturing conditions which must be met and, when the time comes, introduces the results of his research work into the factory. He then returns to the Institute and examines the literature of the subject under investigation, in order to familiarize himself with what others have done on the problem. After this preliminary work, he is assigned a laboratory, and begins what may be termed the test-tube scale of experimentation.

The fellowships which have come to the Institute have been on such diverse subjects as the chemistry of bread and baking, problems relating to petroleum, the corrosion of steel, the technology of soap and soap fats, the bleaching of animal and vegetable oils, problems relating to the manufacture of foods, the development of steam power accessories, the fixation of nitrogen, problems of hydro-metallurgy, the development of pharmaceutical preparations, the technology of glass, the production of nitrogenous and phosphatic fertilizers, and the utilization of mineral wastes.

The Institute is, as its name implies, an organization devoted to industrial research, and as such, it is in a position to assist industrialists in engineering fields as well as in the fields of pure and applied chemistry. Knowledge of the crying need existing for such an institution in Canada cannot be made too widely known. At present, with the comparatively small amount of manufacturing done in Canada, problems a-plenty are awaiting solution, but when once the development of Canada's enormous supplies of raw materials by means of her immense resources of power gets fairly under way, nothing but the most efficient organization will suffice if industry is to receive the impetus it should from scientific progress and research.

The Time Opportune

To-day industries are being established in America which have previously been the exclusive property of the European countries, especially Germany. The United States is at last awake to the necessity of fostering these industries by providing facilities for research, and if Canada is to have her fair share of them she must act at once. We must conduct propaganda to make our manufacturers and capitalists realize the creative power and earning capacity of industrial research. We must remember that after the military operations have ceased we will be at war with the most strongly fortified industrial position in the world. German commerce is not destroyed—merely have some of its antennae been lopped off. However, if we are willing to learn, the outlook is bright. We possess resources, to which Europe has nothing to compare, and with the impetus given by present war conditions, a little faith and sustained effort, and the development of and appreciation by our financiers and business men of the earnings power of research, we may hope to develop a great chain of interlocking industries by science.

The Royal Canadian Institute, in founding the Bureau of Scientific and Industrial Research, is imitating the Mellon Institute of Pittsburg, because it has every reason to believe that this is the most practical plan for accomplishing their purpose yet devised. There is no reason why the same success should not attend it in Canada as in Pittsburg. That institution founded with only the most meagre support has, in less than a decade, grown so that over two score researches are continually in progress and a quarter of a million is annually disbursed in salaries and up-keep. The plan has shown itself sufficiently practical to encourage Pittsburg's two leading bankers to endow it and lend their names to it. The financial returns to manufacturers have already run into millions and on the human side scores of young men have had a chance to distinguish themselves in the field of applied science, at the same time contributing to the wealth and welfare of the people at large. In commenting on the scheme recently in England, Sir Wm. Ramsay and Prof. Henderson (of Glasgow), both recommended its adoption in England and called it "eminently practical."

When Dr. Duncan was founding the Mellon Institute, he met a few leaders of industry, the University of Pittsburgh, and some other interests sufficiently far-sighted to supply the $10,000, with which the institution carried on its early work. Surely Canadian manufacturers, and others will be sufficiently aroused to do as much. The Pittsburg men were asked to give to what then was an unknown experiment — now, the Royal Canadian Institute is asking support for an undertaking that has been tried and proved successful. In addition to the work of its bureau, the Royal Canadian Institute will continue its other scientific work. The Institute has to its credit many notable achievements including the establishment of standard time throughout the world and has been recognized as of national importance.

Vol. XV. JUNE 1, 1916 No. 22

CAPTURING ENEMY TRADE

WE are inclined to think that up to the moment little headway has been made, or more properly speaking, little enemy trade has either been appropriated or negotiated. True it is that much organization toward that end has been created, organization at once influential both from the nature of the commercial interests concerned and from the Governmental recognition exemplified in Trade Commission appointments.

It is quite evident that German trade competition after the war is being anticipated, whether the latter arise from known facts in the possession of those whose official positions necessarily keep them posted as to our enemy activities, or whether it be simply a logical deduction based on enemy experience in the past. No scheme of real practical value has yet been evolved, much less launched, whereby the end sought has been brought appreciably nearer to fulfilment. Suggestion, doubtless, has been plentiful, but all of it displays a lack of knowledge of what there is intended to combat and conquer.

Most of the schemes propounded are, it seems to us, much too ambitious and are indicative of the "wish being father to the thought." They have further the somewhat undesirable tendency to, if not frustrate individuality, at least stifle it, with the result that inaction on the part of commercial and manufacturing managements ensues. Initiative in the unit sense ceases to be a factor, and the impression grows that the task of capturing enemy trade is so gigantic as to require some drastic legislative enactment or something of an equally stupendous nature.

Trade and commerce are constitutionally complex, and in a world-sense are very much so; they are, however, readily amenable to individuality of operation. Their essence is individual enterprise and will continue so to be irrespective of any national or Empire plan of campaign to capture enemy trade. It follows therefore that each Canadian manufacturer should act his own part in the latter direction—in a word set about securing his particular share, and in the event of collective organization or Government enactment materializing, appropriate what further aids these may afford.

It has been said that each manufacturer can think out a plan to develop some part of his business a little more than has yet been done or has even been attempted, and this without waiting for ambitious and all-comprehensive schemes that are probably beyond the ken of human to evolve. Each can be keenly alert and active to seize the many opportunities—big and little now presenting themselves, and by so doing not only help himself, but contribute the quota necessary to our national and Imperial achievement.

SHIPBUILDING IN CANADA

IT is not to the question of whether the vessels built by Canadian shipbuilding plants now or in the immediate future would contribute to the relief of the war-created shipping stringency, but rather the taking of steps towards our future national commercial ascendency that Sir Robert Borden and his Government should turn their attention and be prepared to give national help and active support. The fostering of shipbuilding in Canada is perhaps at the moment the livest topic in the realm of public opinion from our Atlantic to our Pacific Coast, and it is just sufficiently deep-rooted as to be unmoved by shallow excuse or unnecessary parleying.

Canadian shipbuilders are prepared to show not only what they can do to offset war-time disabilities, but to further our shipping and commercial enterprise following peace; the indifference shown by and repeated rebuffs at the hands of so-called representative Government at Ottawa, notwithstanding.

There is a widespread desire that Canada should not only possess a larger merchant marine, but also that she should play the major part at least in producing it. All who are in accord with a shipbuilding propaganda do not of course fully appreciate what is involved. It may not be too clearly apparent to many that construction costs in Great Britain in pre-war days were very much lower than those in Canada, relative to both wages and material, and that the Motherland was our real and only competitor, the vessels built by her entering Canada duty free. To stimulate Canadian shipbuilding by a tariff enactment against Britain and admit at the same time materials of construction, duty free, are directions in which public opinion is not likely to express itself too favorably. The opposition of our manufacturers generally would not fail to assert itself, and not without good reason, as the altogether free importation of shipbuilding commodities would hinder rather than help thereby the myriad industries auxiliary to the prosecution of shipbuilding and marine engineering on a comprehensive scale.

Shipbuilding is wanted to be firmly established on our shores as much for the sake of our general industrial enterprises as for its own; therefore, the plan or scheme for its encouragement must embody that provision. A bounty as proposed by Col. Cantley in his recent address before the Canadian Manufacturers' Association at Montreal, seems therefore the only reasonable solution to meet fully the situation in its diversity, and we would suggest that our shipbuilding administrations get together so as to determine both the bounty extent and its probable period of duration. By doing so, they will be able to place their proposition before the authorities at Ottawa in concrete form and therefore with more certainty of its being at last accepted.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

Prices Per Lb. Unless Otherwise Stated.

quoting up on galvanized sheets, despite the decline in the price of spelter; in fact, local dealers report an advance of 25 cents on Queen's Head and 10 cents on Fleur-de-Lis; present quotation being $7.75 and $7.35 respectively. Recent heavy demand for wire and wire products may result in a further advance.

Metals

Copper is quiet and weaker. Tin is developing a little strength, following a quiet period. Spelter continues to fall off, and buyers are scarce. Lead is in poor demand, and small dealers are offering metal at reduced figures. Antimony is still going down and demand is light.

Copper.—After June 1st no buying will be allowed in Britain without a Government permit, the prohibition of speculative dealings having resulted in bringing considerable metal on the market. A recent decline of £4 on electro is noted in London reports, which indicates a drop of £10 in about two weeks. During the same period the quotation on standard spot shows a decline of £20, the current nominal price being £121. With a decline of approximately £15 in two weeks, futures are quoted at £120. New York reports a dull market, with an evident undertone of weakness. Prices on the New York market are relatively firm, nominal quotations being 29 cents for lake and 28½ cents for electrolytic. With a decline of 1 cent on lake, local dealers are quoting 32 cents, with prices firm on electro and castings, which are 32½ and 31 cents respectively.

Tin.—A firmer tone prevails in the tin situation, and prices are becoming steadier, satisfactory quantities arriving from London, with the result that the spot market is well supplied. London reports a quiet market on declining prices; standard spot is now quoted at £193, with futures at the same figure. Straits tin is quoted at £194, which is £4 lower than two weeks ago. New York quotations, after a decline of 1¼ cents on the week, are again advancing, a recent advance of ¼ cent placing the nominal price at 48 cents per pound. Local conditions are unchanged, and dealers are quoting last week's price of 49 cents per pound.

Spelter.—Despite the fact of lower prices being quoted on spelter both here and abroad, the market is very quiet and business is relatively dull. It is believed that still further reductions are not improbable. A decline of £5 on the London market has not resulted in any material activity, as the cost of importation is still very high. Present quotations are £90 for spot and £75 for futures. Easier prices also prevail in New York, and the current nominal price is about 14¼ cents per pound. Conditions abroad have affected the local situation, and dealers here are quoting 20¼ cents, which is a decline of 1 cent.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., May 29, 1916.—Continued activity in the production of large shells is one of the present features of the metal working trades. While this is gradually stimulating domestic activity, the exceptionally high prices of material and labor prevent any great development in that direction. The producing end of the steel industry exhibits unceasing energy, although the market is comparatively quiet, pointing to some slight relief in certain quarters. The metal market conditions continue quiet, quotations for most metals showing a declining tendency.

Pig Iron

The pig iron situation is unchanged; capacity production still prevails, and the demand for steel making pig continues to be greater than the supply.

Steel

While price advances are not so pronounced as a few weeks ago, the strength of the market does not indicate any tendency to weaken; in fact, any change will likely be upward instead of downward. Pittsburg reports an advance of $5 per ton on rivets, and a rise of from 5 to 10 per cent. on nuts and bolts. Deliveries on billets and sheet bars are better. The demands on the plate mills continue heavy, and car builders and shipyards are experiencing great difficulty in securing sufficient material for their requirements. The mills are still

Lead.—In the absence of the usual demand for lead, the situation has become somewhat quiet, and prevailing conditions show an easier tone than a few weeks back. London markets are quiet, and prices are easier, £31 5s. being asked for spot and £31 10s. for futures. Local dealers report fair business, with general conditions unchanged and prices firm at 9¼ cents per pound.

Antimony.—The apparent scarcity of a few weeks ago has now changed into one where the supply is greater than the demand. During the past two weeks New York has declined 10 cents, the present quotation being 26 cents per pound and further reductions are expected. Local dealers report a weak market on declining prices; a drop of 4 cents during the week placing current quotations at 38 cents per pound.

Aluminum.—General market conditions in aluminum are unchanged. It is reported that some business is being done by regular customers at about 35 cents per pound for next year's delivery. Local prices are nominal at 68 cents per pound.

Machine Tools and Supplies

The conditions are gradually assuming more normal proportions, as the demand for war machinery is constantly decreasing. Inquiries for single tools or small lots are still being made, but complete equipments for munition making are no longer required. Deliveries on certain tools are still delayed, and in some instances months must elapse before delivery. Domestic trade has greatly benefited, indirectly from war conditions, as many lines of industry have been added to, and new ones developed, resulting in considerable machine equipment being required.

Old Materials

General decline in all metal scrap is reported, and dealer's business is very brisk. Copper scrap has declined 1 cent all round. Machine compositions on a decline of 1 cent are quoted at 16 cents. A similar reduction puts turnings at 13¾ cents, and brass clippings are now 15¼ cents. Old lead is weaker by one-half cent, heavy being quoted at 6½ and tea at 5¾ cents. Scrap zinc is quoted at 12½ cents, showing a decline of 2 cents. Other scraps are unchanged, but with a weaker tendency.

Toronto, Ont., May 30.—Business continues active, being considerably better than last year around the corresponding period. The outlook as far as demand is concerned is bright but as regards production the situation is not so favorable. The difficulties that are being experienced in getting raw materials and the scarcity of labour due to enlistments are already tending to curtail production. For these reasons and also because of the increased cost of raw materials, high prices on all kinds of machinery and products composed of iron or steel will obtain for some time to come.

It is understood that further contracts for 8 in. and 9.2 in., shells have recently been placed in Canada and as a result enquiries for large-swing lathes have been sent out. The machine tool makers are very busy and the trade is in a prosperous condition. There are some price changes to note in the steel market affecting steel bars and boiler tubes, advances being registered in both cases. The ingot metal markets are weaker throughout the list and all metals are lower with the exception of lead which is unchanged.

Steel Market

Although there is still a tendency towards higher prices for steel products, there are indications that the market is reaching the high water mark. There is, however, no falling off in demand and deliveries are, if anything, getting more backward. There is, therefore ,little probability of any pronounced weakness developing in the market for some time to come and prices, no doubt, will be maintained at a high level for the rest of the year. The steel market in the United States is steadier and if this condition is maintained, the effect is bound to be felt in Canada. The principle price changes this week include steel bars which have advanced 25c and are now quoted at $3.25 per 100 lbs. base. Even at this price they are lower than Pittsburgh bars would be laid down here; the inference is that there may be a further advance at no distant date. Another advance in lapwelded boiler tubes has been made, and still higher prices are quite possible. The output of iron and steel boiler tubes at present is exceptionally heavy and the mills are backward in deliveries. Prices on wrought iron pipe are unchanged but an advance is expected any time on account of the skelp situation. Skelp mills are filled with orders for four or five months ahead and are not taking new orders. Boiler plates are very firm at last week's advance and deliveries are running into six to eight weeks.

The market for sheets continues strong and prices are being well held. Deliveries from most sheet mills are running into the latter part of the third quarter while production is being delayed owing to the insufficient supply of sheet bars, and delays in deliveries from the steel mills. The market for galvanized sheets is steady and the situation generally unchanged. Although spelter has declined, the price is not low enough to materially benefit the galvanizing trade.

The steel market in the United States continues strong at current quotations and specifications-against-contract continue in large volume. New business is being offered to the mills for the second quarter of 1917, which is an indication that the demand for steel is not falling off very much. Prices are firm and steady, and the opinion is generally held that the top has been reached but no marked decline is expected for some considerable time. Steel bars are unchanged at 3c, plates 3.75c and shapes 2.60c Pittsburgh.

Pig Iron

The market continues strong and quotations firm but unchanged. Foundries are buying carefully but the tonnage is increasing. The importations of pig iron from Great Britain are increasing in volume, the tonnages for April being valued at about $123,168 as against $24,000 for the corresponding month of last year.

Old Materials

There is nothing of particular interest to note in the scrap market. The situation is generally much the same as during the past few weeks. Quotations on copper and brass are a shade weaker, otherwise prices are unchanged. There is a fair demand generally for old materials and the market is steady.

Machine Tools

There is a better tone to the market this week due to some good enquiries which have been received by dealers for lathes for machining 8 in. and 9.2 in. shells. These are mostly of the single purpose type and as deliveries can be made promptly, some attractive business is expected. An interesting development in the trade is the purchase of a site at West Toronto, by the Russell Motor Co., who propose establishing a plant there for making bicycles and skates. Deliveries of standard machine tools are somewhat easier to obtain though it is still necessary to wait several months for some types.

Supplies

Business continues active and prices are still very firm. There have been

---

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

comparatively few price changes this week, the more important being on linseed oil and turpentine which have both declined. The oil market is weak on account of very light demand, the price quoted now being 82c for raw, and 85c for boiled oil. Turpentine is being quoted at 68c per Imperial gallon

Metal Market

The metal markets are dull and prices in many cases have declined. One of the reasons for the easier tendency in most metals, with the single exception of copper, is that production has been increased to a degree equal to the present demand. The dullness in copper is a result of the buying movement having been succeeded by a period of inaction, the position of this metal is nevertheless, a strong one. The tin market has been influenced by the weakness in other metals and has declined. The spelter market is very weak and lower on light demand. The "Trust" price for lead is unchanged but the outside market is a shade lower than it was last week. Antimony and aluminum are weak and quotations are lower. Solders are unchanged but have a weaker tendency.

Copper.—The market has declined in London owing to a recent Government order which prohibits speculative trading in copper on the London Metal Exchange after May 31. The New York market is steady but dull at unchanged prices. The buying movement in copper appears to have come to an end for the time being and the market is, therefore, less active and easier. The position of copper is as strong as ever and a recovery may be looked for. Copper has declined ½c locally and quotations are nominal at 31½c per pound

Tin.—The market is weak and lower for spot tin due to an increase in visible supplies and falling off in demand. The market for futures is firmer and quotations unchanged. Tin has declined 2c and quotations are nominal at 52c per pound.

Spelter.—The market is lower both in London and New York. The demand for spelter is very light and price recessions are being made each day. Spelter has declined 2c and is now being quoted at 19c per pound.

Lead.—The demand for lead is light and the market has a weak tendency. The "Trust" price is unchanged at 7.50c New York but the outside market is lower. Prices in the outside market are being established by second hands, who are offering small tonnages at concessions. Lead is unchanged locally at 9½c per pound

Antimony.—The market is neglected and buyers show no interest despite reduced prices. Quotations are lower and nominal at 42c per pound.

Aluminum.—The market is weak and lower, and, while the demand is somewhat better, the supply is larger. Aluminum has declined 2c and is now quoted at 66c per pound.

OUR NEED OF AN OCEAN MARINE

IN an article on "Canada's Need. A Great Ocean Marine," in the second number of Canada Steamship Lines' new monthly publication. The By-Water Magazine, Roy M. Wolvin, of Winnipeg, discusses one opportunity that exists for keeping in Canada money that is now being diverted abroad. He says in part:

"I will only speak of the grain grown in our great western provinces and shipped through the ports of Port Arthur and Fort William to lake ports in the United States for furtherance by rail to United States seaboard and thence by vessel to foreign buyers. In the figures I have prepared I will not include our grain moving all rail through the United States or that shipped by lake from the ports of Duluth and Superior.

"Of our 1915 wheat, oats and barley crop, there was shipped by water to U. S. lake ports during the fall navigation period only of 1915, the following:

98,346,404 bushels of wheat
3,646,844 bushels of oats.
1,836,263 bushels of barley.

103,829,511 bushels of grain (excluding flax).

"The average lake rate which this grain paid to United States vessels was about four cents per bushel on wheat and barley, and three and one-quarter cents on oats, making a total contribution to the United States for its lake sailors and lake vessels of about $4,125,828. The railroad rates at and east of Buffalo to New York for export are: Wheat, six cents per bushel; barley, five and one-quarter cents per bushel, and oats, four cents per bushel. Using this rate as applying on all this grain, we find we have made our little contribution in cash to the United States railroads and railroad employees of about $6,143,061.

"The charges at New York on this grain for loading full cargoes are one-half cent per bushel, and for floating to steamers which do not come to elevattors nine-tenths of a cent per bushel. Using the full cargo basis, we find we contributed to the elevator facilities in Atlantic ports of the United States $519,147.

"To move this grain from U.S. ports to foreign purchasers undoubtedly required 500 steamers, each of which in stevedoring charges, supplies purchased, and repairs made, would average a cash outlay in port of $1,200 or a total of about $600,000.

"So we find that we have calmly turned over in cash to our neighbors to the south:

Lake vessels	$4,125,828.00
Railroads	6,143,061.81
Port charges	519,147.06
Ocean vessel port disbursements	600,000.00
	$11,388,036.87

"Present indications are that the wheat, oats and barley now in our western provinces, the remainder of our wonderful 1915 crop, will contribute just about the same number of dollars to the United States, making a grand total from the 1915 crop of about $23,000,000. This 'real money' can be retained in Canada only by the greatest protection to her lake vessels, increased railroad and ocean port facilities, and an assured supply of ocean vessels trading from Canada. Our statesmen at Ottawa are keenly alive to this loss which we are suffering every day, and I feel sure will develop our Eastern Canadian facilities so as to properly care for this great tonnage of grain from the west and will make every effort to the end that Canada may have a proper supply of her own ocean tonnage. I can go further and dream of the not far distant day when this grain on the ocean will be carried in Canadian owned and Canadian manned vessels, built in Canadian shipyards. This will turn into the coffers of Canada the ocean freights now being paid to others and we shall then retain the full price of the grain instead of so gracefully donating such a large proportion to others."

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

ICE-BREAKER "J. D. HAZEN" SOLD

AS forecasted in the speech of the Prime Minister at the launch of the St. Lawrence ice-breaker, J. D. Hazen, that vessel has, we understand, now been sold to the Russian Government. It will be completed during the coming fall, and, it is hoped, will be delivered in time to aid in the work of keeping open Russia's winter port of Archangel.

This is the third Canadian vessel of the kind to be turned over by the Government to the Czar's Empire during the last two years. The Minto and the Earl Grey have been similarly disposed of, and have been sent across the seas to enter the service of Britain's Ally. They have already done splendid work, and in the expression of the Russian Government's gratitude for the transfer of the vessels it was emphasized that they have paid for their value many times over in the facilities they have afforded for the landing of cargoes of munitions at Russia's White Sea port. The Minto and Earl Grey were small vessels, however, compared with the J. D. Hazen. It is understood that certain changes in construction will be made to meet the wishes of the Russian authorities before being turned over to them, which will enable the vessel to be used for the carrying a certain number of passengers, as well as being used for ice-breaking purposes proper.

Control of Empire Metal Industry.—The Prime Minister of Australia, stated, at a recent interview, that he was hopeful of reaching an early solution of the zinc problem by an arrangement which would enable the whole of Britain's spelter requirements to be manufactured in the Commonwealth. This would destroy the German influence, and control over the spelter trade, and establish on sound business lines a truly Imperial scheme of industry. As a result of his negotiations with leading British representatives of the metal industry, Mr. Hughes expects shortly to be able to put the matter before the Imperial Government in a definite form.

TRADE WITH GREAT BRITAIN

THE following are the figures for the trade between Great Britain and Canada in the undermentioned articles during April:

	April, 1915.	April, 1916.
Exports from Canada:		
Wheat	£651,467	£1,009,496
Wheatmeal	164,821	376,904
Barley	299	110,409
Oats	23,242	169
Bacon	318,745	466,339
Cheese	15,687	45,960
Eggs	1,092	1,163
Canned salmon	118,913	199,796
Canned lobsters	12,830	5,504
Fir	137,339	70,195
Imports to Canada:		
Spirits	27,213	46,125
Wool	43,795	46 269
Pig iron	6,828	25,384
Galvanized sheets	4,389	4,960
Steel bars	5,003	20,569
Pig lead	815	1,210
Tin, unwrought	27,883	16,924
Cutlery	5,330	5,976
Hardware	3,660	4,343

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Toronto, Ont.—The Sheet Metal Products Co., will build an addition to their plant to cost about $6,000.

Alliston, Ont.—The Benedict-Proctor Mfg. Co. are in the market for a 50 h.p. engine and boiler.

Welland, Ont.—The Dominion Incinerator Co. has purchased a site here, and will erect an incinerator.

Montreal, Que.—The Canada Stove Co. will build an extension to their factory at St. Laurent near here.

Montreal, Que.—The Canadian Tube & Iron Co. have commenced the erection of a factory, estimated to cost $3,000.

Renfrew, Ont.—The Renfrew Electric Mfg. Co. have commenced the erection of an addition to their premises, estimated cost of $5,000.

Trenton, Ont.—It is reported that the Canadian Sprayer Co. will build a plant here for making sprayers and gasoline engines.

Weston, Ont.—The Russell Motor Car Co. have purchased a large block of land from the Chew Estate, and will immediately erect a big plant, which will be used in the manufacture of skates and bicycles.

Montreal, Que.—The Canadian Cotton Co. will instal a large motor generator in the mill at Cornwall, Ont. R. S. Kelsch, consulting engineer, Power Building, Montreal, has the matter in hand.

Hamilton, Ont.—The Dominion Sheet Metal Co. is adding two buildings to its plant—one 20 ft. x 100 ft., for storing metals and by-products, and one 40 ft. x 80 ft., for additional black sheet storage.

Montreal, Que.—It is reported that the Du Pont Powder Co. has organized a $10,000,000 subsidiary company, which will operate exclusively in Canada. The company has secured a water power and other properties on the Saguenay River, and intends commencing construction at an early date.

Kingston, Ont.—The plant of the North American Smelting Co. has been rented by a Toronto firm, of whom J. Mercer is a representative. The plant is being overhauled and the operations of smelting lead are to be commenced in a very short time.

The Waldon Co., with offices at Winnipeg, Montreal, and Toronto, are now manufacturing their Spencer boilers at Penetanguishene, Ont. Heretofore these boilers were made in the United States. The company's business has grown to such an extent that it has become necessary to establish a Canadian plant.

Welland, Ont.—Further extensions will be made to the plant of the Canada Forge Co., to cost $50,000. The present addition is to be a steel and brick building, 60 x 227 ft., with crane runway extension, 150 ft. long, equipped with electric cranes and loading rack for the inspection and shipment of shells.

Municipal

Simcoe, Ont—The ratepayers on May 22 voted in favor of a by-law to loan $20,000 to the Unique Shoe Co.

Ingersoll, Ont.—The town council will proceed with the installation of the proposed new street lighting system.

St. John, N.B.—The city council contemplate extensions to the waterworks system, at an approximate cost of $230,000.

Hull, Que.—It is proposed to spend $146,000 on extensions to the waterworks, electric light and fire alarm systems. A by-law will be voted on to authorize the expenditure.

Simcoe, Ont.—The shoe factory bylaw passed by a substantial majority here on May 22. It is expected that building operations will be started shortly.

Toronto, Ont.—The Board of Control has recommended that the contract for the erection of a new car barn on St. Clair Avenue be awarded to R. Chalkley & Sons, the lowest tenderers, whose price is $24,435.

Niagara Falls, Ont.—The Stamford Township Council has adopted a resolution favoring the plan of the Ontario Hydro-Electric Commission to purchase the plant and lines of the Ontario Distributing Co. for $29,000. A by-law will be voted on to raise the necessary funds.

Sarnia, Ont.—A letter has been received in the city from the Provincial Board of Health recommending that a 30-in. pipe be laid under the bed of the river to a point 200 feet from the shore, where a crib will be erected about 4 feet above the bottom of the river. The water at this point is about 40 feet in depth and the pipe would not be interfered with by the ice in winter. An automatic chlorine machine will have to be installed to purify the water.

General Industrial

Harrow, Ont.—The W. Clark Co., of Montreal, will build a canning factory here.

Ottawa, Ont.—Grant, Holden & Graham will build a factory here to cost about $30,000.

Toronto, Ont.—The William Davies Co. have purchased the Taylor Soap Works, which will be equipped and used as a beef house.

Elmira, Ont.—The machinery for the new knitting factory to be established here will arrive in a few days, and will be installed in the Elmira Felt Co. premises.

Gananoque, Ont.—A sawmill and cheese factory owned and managed by Charles Wilcox, at McIntosh Mills, was totally destroyed by fire recently. There was no insurance.

Vancouver, B.C.—Fire on May 29 partly destroyed the plant of the New England Fish Co. and the Alberta-Pacific Grain Elevator here. The loss is estimated at $600,000. No lives were lost.

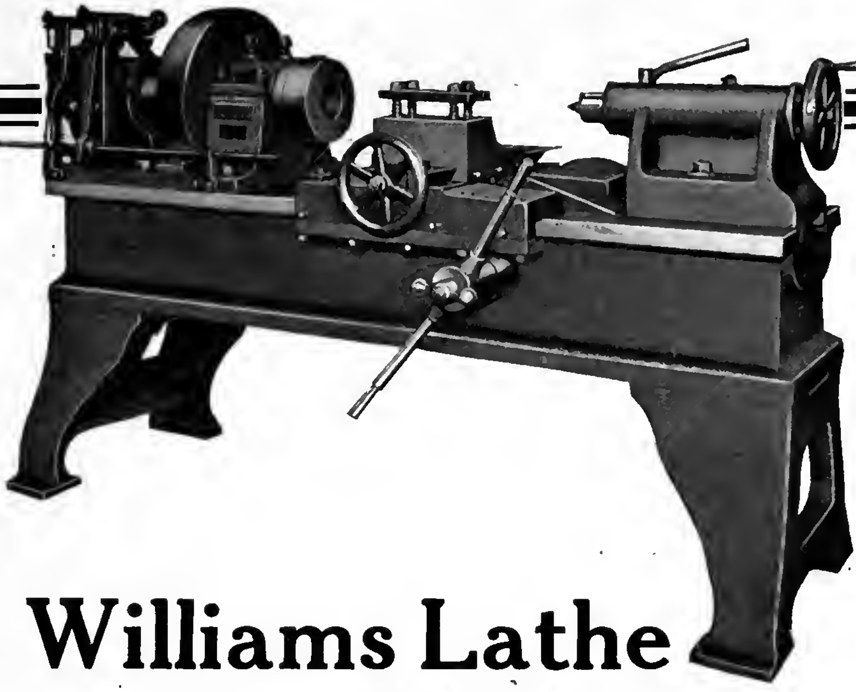
Saskatoon, Sask.—An effort is being made by the Board of Trade to induce the Lake of the Woods Milling Co. to build a mill here to replace the plant recently destroyed by fire at Medicine Hat.

Barrie, Ont.—Messrs. Brown and Morden, representing a company that is being organized to manufacture condensed milk, are negotiating with the Board of Trade regarding the installation of a factory here.

Markham, Ont.—The Purvis Salts Co., which has been incorporated recently with a capital of $40,000, will erect a factory here for making health salts and mineral waters. A. W. Burk, of Toronto, is president of the company.

Tilbury, Ont.—The F. S. Carr Rubber Co., which has been operating here for about four years, is moving its business to Granby, Que., where they have purchased the factory and equipment formerly operated by the Walpole Rubber Co. in that town.

Boring — Turning



The A. R. Williams Machinery Co., Ltd.

64-66 Front Street W. Toronto, - Ontario

SPECIFICATIONS

Length of bed ......8' 6"
Width of bed ....19½"
Depth of bed ....13"
Swings over bed.......19"
Length of saddle ....34½"
Feeds..1-16", ⅛" and 3-16"
Takes between centre 4' 2"
Pilot wheels geared 4 to 1.
Ball thrust throughout.
Front Bearing of Spindle (6" shell), 8 3-16" x 7½", Bored 6⅛".

SPECIFICATIONS

Front Bearing of Spindle (4.5" shells), 6½" x 7½", Bored 4 19-32" dia.
Rear Bearing of Spindle, 5¾" x 7½".
Flange on Front of Spindle, 12" dia.
Size of Driving Pulley. 13" x 8" face.
Dia. of Turret (6 holes for bars 3" to 3¾" dia.), 20".

Williams Lathe

For Boring 4.5" and 6" Shells

A machine must have passed a 100% efficiency test to have our mark beside it. We could not afford to risk our reputation as Canada's Leading Machinery House to put before the public a machine of inferior quality. A careful study of the illustration and specifications will reveal to you a machine of great strength and durability. Write us for full description and prices.

NO SCREW-CUTTING TOOL CAN BE SUCCESSFULLY OPERATED

Without Proper Grinding or Sharpening

THE GEOMETRIC CHASER OR DIE GRINDER

is a machine carefully designed and constructed for the correct grinding of thread chasers and dies.

Its use is economy where threading tools are employed.

It not only keeps all the chasers of a set in condition for perfect work, but at the same time prevents excessive wear on one or two of the chasers.

THE GEOMETRIC grinds any make of thread chaser, whether of a stock or special type. Also fitted with a second grinding wheel for ordinary tool grinding.

SEND FOR DESCRIPTIVE BOOKLET.

The GEOMETRIC TOOL COMPANY

NEW HAVEN, CONN., U.S.A.

CANADIAN AGENTS: Williams & Wilson, Limited, Montreal; The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg, St. John, N.B.

Collingwood, Ont.—A recently organized syndicate propose establishing a factory here for making wood and metal specialties. The promoters are asking the town for a loan of $15,000. F. Kent and J. A. Sinclair, of the Seamen Kent Co., are interested in the proposition.

Sarnia, Ont.—A representative of a concern capitalized at $10,000,000, whose name has been withheld, is in Lambton district with the idea of erecting a sugar beet factory. The concern has heard of the excellent results which have been produced in this part of Western Ontario, and is fully investigating conditions.

Campbellford, Ont. — The by-law authorizing a loan to the Northumberland Paper & Electric Co. of this town of the sum of $30,000 to assist it in the rebuilding of its paper mills recently destroyed by fire, was carried on May 22. The company is proceeding with the erection of a much larger plant than their former one.

Contracts Awarded

Galt, Ont.—The Hamilton Bridge Works have the contract for the steel work for the extensions to the Goldie & McCulloch Co. plant.

St. John, N.B.—The Nova Scotia Construction Co. has been awarded the contract for the construction of the portion of the Valley Railway from Gagetown to Westfield, a distance of 40 miles.

St. Catharines, Ont.—Sherwood & Sherwood, Mail Building, Toronto, have received the contract for the erection of a plant for the McKinnon Dash & Hardware Co. here, at a cost of $75,000.

Tenders

Toronto, Ont.—Tenders for light fixtures for the new Registry Office will be received up to 6th June, 1916. Plans and specifications may be seen and forms of tender obtained at the office of the city architect, City Hall, Toronto.

Toronto, Ont.—Tenders will be received at the Department of Public highways of the Province of Ontario up to June 9, for the supplying of motor vehicle markers required for the year 1917. Specifications and forms for tender may be obtained from W. A. McLean, Deputy Minister of Highways.

Toronto, Ont.—Tenders will be received by the Chairman, Board of Control, City Hall, up to June 6, for the supply and delivery of coal meters for measuring coal at Main and High Level Pumping Stations. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Winnipeg, Man.—Tenders will be received at the office of the Board of Control, up to June 5, for the supply of one combination gasoline pumping engine and hose wagon, with a pumping capacity of 700 gallons per minute, and capable of carrying 1,000 feet of 2½ inch fire hose. Form of tender may be obtained at the office of the chief of the fire department, Central Fire Station.

Building Notes

Toronto, Ont.—The T. Eaton Co. have been granted a permit to erect a twelve-storey manufacturing building on the corner of Alice street and Downey's Lane at an estimated cost of $625,000.

Ottawa, Ont.—The Mint at Ottawa is to be extended and enlarged in its operations. It is understood that this extension will be of a temporary character, but of considerable magnitude. The work is to be got under way at the earliest moment possible. The new building will be built in close proximity to the permanent structures.

Ottawa, Ont.—The restoration of the Federal Parliament Buildings is to be done partly on the percentage basis and partly by contracts based on competitive tenders. An arrangement has been made with the Peter Lyall Construction Co., Montreal, which cleared away the debris, to reconstruct the main walls of the building, and do certain other work the total estimate of which is around two million dollars. The company will be paid 8 per cent. on the actual cost of the operation. For the inside of the building, such as the construction of the chambers, plumbing, heating, painting and decoration, competitive bids will be asked. The arrangements are in the hands of a joint committee of Parliament, representing both Houses.

Personal

A. F. Macallum, for seven years city engineer of Hamilton, Ont., has been appointed Commissioner of Works of the city of Ottawa, Ont.

J. E. B. Phelps, former chief engineer of the Sarnia Electric Light Co., has been appointed general manager of the Sarnia Hydro-Electric Commission.

Col. Noel Marshall, president of the Standard Fuel Co., Toronto, and of the Canadian Red Cross, has arrived in London, England, in the interests of the Society.

Lieut. W. Roy Russell, of the 168th Battalion and recently with the John Morrow Screw & Nut Co., Ingersoll, Ont., was recently presented with a pair of .45 Colt automatic pistols by the members of the staff. President J. Anderson Coulter made the presentation..

Hon. R. H. Brand has been appointed an additional member of the Imperial Munitions Board to act as its representative in London. Mr. Brand same out to Canada last fall with Lionel Hichens, and assisted in the reorganization of the Shell Committee as the Imperial Munitions Board.

Major Norman C. Pilcher, formerly general manager of the Sherbrooke Railway & Power Co., has been killed in action in Flanders while serving with the Canadian Mounted Rifles. Major Pilcher was born in England 36 years ago, but had lived in Canada for 24 years. He went to South Africa with the Canadian contingent during the Boer War. On returning to Canada, he was for a time manager of the Fort William Tramways, coming from that city to take the post in Sherbrooke, which he held until leaving for the front.

Wood-Working

Ocean Falls, B.C.—Work will begin shortly on the construction of a lumber mill for the Pacific Mills.

Elmira, Ont.—The erection of the new planing mill is well under way. The building, 70 by 90 feet, is partly up, being concrete, with walls 14 feet high. The interior will be fitted up with modern and up-to-date machinery.

Marine

Commander D. Dow, late captain of the Cunarder Lusitania, is at present visiting his brother in Thamesville, Ont. He will be in Toronto later, and will be the guest of Sir William Mulock.

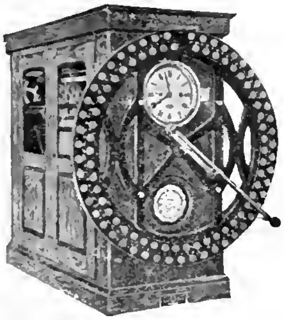
Vancouver, B.C.—The first steel, ocean-going cargo steamer to be constructed in British Columbia will be built at the Wallace Shipyards, North Vancouver. Work will be commenced at the end of June or beginning of July, and the vessel is to be delivered early next year. The steamer is for the firm of Dingwall, Cotts & Co., Pacific Building, Vancouver, and also of London, England, who, through their Vancouver manager, John Eadie, placed the contract and signed it up. The steamer to be built will be 315 feet long and 45 feet beam. She will have a carrying capacity of 5,000 tons and a speed of nine and a half knots. The plans show her to be a single deck, single screw steamer, with two boilers, triple-expansion engines, eight

Here's the way to save a year's dividends

You have competitors? Yes! Look around and you'll see they use International Time Recorders. That's why they are SUCH competitors.

There's no argument about "working time" being the greatest of all raw materials you buy, yet many manufacturers permit four leaks a day in the supply every man on their pay-roll sells them.

"Walking time"—there's the biggest leak. The time the employees take *after* ringing in on the Recorder and *before* they get to work.



Check this loss. Put an International Time Recorder at the door of each department. Then it's up to the foreman to see that every man is busy at his bench or machine—and he'll do it.

Our big, new Canadian factory is prepared to make a Time Recording system to exactly suit any business—even yours.

Prices and new literature on request. Write to-day for it. No time like the present to start saving money.

INTERNATIONAL TIME SYSTEMS

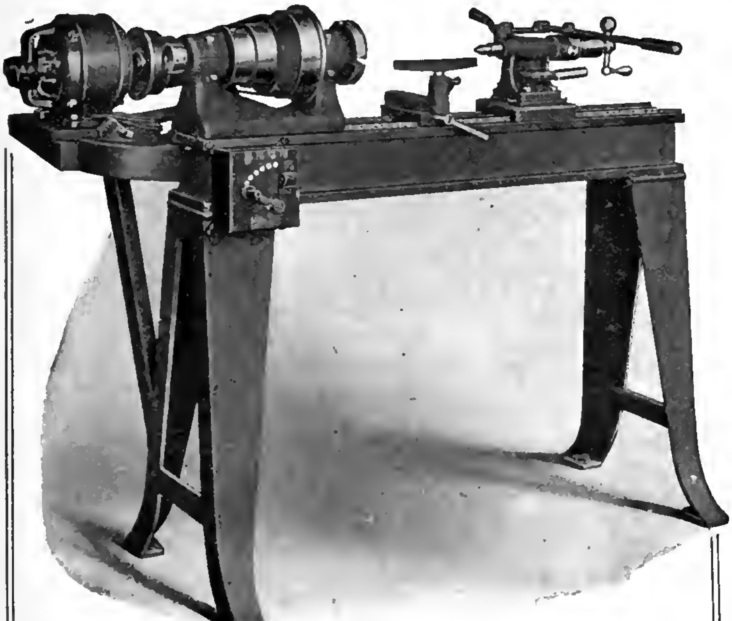
MONTREAL: W. A. WOOD, Sales Agent, Corner McGILL and CARTIER STREETS



Motor Driven Speed Lathe

This style of motor drive employs a constant speed motor mounted on a plate having an extension arm to support a bearing for the outer end of the motor shaft. The motor plate is fitted to a slide on a shelf which is securely fastened to the back of the lathe bed. The motor plate is moved by means of a screw which tightens or loosens the belt. A four-step cone pulley on the motor shaft is belted to a four-step cone pulley on the spindle. This gives the same speed variation as when a countershaft is used, and by means of various size cones on the motor a wide range of speeds are obtainable.

The lathe spindle is made from high carbon steel, ground to size, and running in self-oiling bronze bearings. The tailstock has screw and lever feed. The bed is crossed-braced and all clamping levers are above the ways.

THE GLOBE MACHINE & STAMPING CO.

CLEVELAND, OHIO

winches, and four big hatches. She will be built to Lloyd's highest classification under special survey. The vessel will have four watertight bulkheads, and wood for hull and deck will be British Columbia fir.

Trade Gossip

The Fisher Motor Co., the E. Long Mfg. Co., and J. R. Eaton & Sons, all of Orillia, Ont., have joined in presenting the 177th Battalion with a motor truck. The truck will be built by the first-named firm.

Port Arthur, Ont.—The "Bull" tractor, which is a product of the Western Dry Dock & Shipbuilding Co. plant, Port Arthur, and was recently placed on the Western market, can now be operated by either gasoline or kerosene. This is expected to prove a great advantage to manufacturers and to farmers, on account of the desirability of using kerosene instead of gasoline, which has advanced enormously since the beginning of the war.

M. Beatty & Sons, Welland, Ont., have received an order for a complete coal handling outfit consisting of steel derdick, triple drum, electric hoist and clamshell bucket from the Canada Glue Co. of Brantford, Ont.; also an order from the Northern Canada Power Co. for hoisting engine, boom swinger and steel stone skips for use on the enlargement of the hydro-electric project near Timmins, Ont.

Canned Goods Embargo Raised—The Dominion Government has been informed that the embargo, placed by the Imperial Government on imports of canned fruits, vegetables, etc., has been raised, in so far as it affects these imports from British Dominions. The question is of considerable importance both to the producers and canners in this country, and has been the subject of numerous inquiries since the original order was promulgated.

British Industries Fair. — In consequence of the satisfactory results achieved by the two British Industries Fairs already held, the Board of Trade propose to organize a similar fair in London next year (1917), from Monday, February 26, to Friday, March 9, inclusive. Full particulars will be announced in due course. Participation will again be confined to manufacturers, and admission (by invitation) to wholesale buyers.

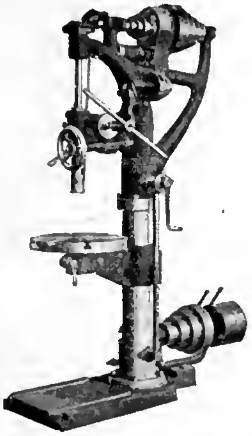
Motors Cars Cost More.—Materials which enter into the construction of automobiles since the war began have increased as follows:—Steel, $29 a ton to $60; copper, 13 cents to 30 cents; brass, 13 cents to 36 cents; aluminum, 20 cents to 65 cents; skilled labor, 20 per cent. It is understood that manufacturers expect to overcome this by advances of $50 to $300 per car, provided gasoline does not rise further and cut down the number of car buyers.

Ottawa, Ont.—Plans and specifications are being prepared here for a flax mill, costing $10,000, to be used entirely for experimental purposes. The new mill, according to G. G. Bramhill, Dominion flax official, will be modern in every way. The latest machinery necessary for the manufacture and improvement of flax fibre will be installed and many of the machines used in European countries will be secured. The object of erecting this mill is to locate in Canada the best districts adapted to flax growing.

Orillia, Ont.—The rejection of the Hydro agreement involves the town in further capital expenditure of $80,000 to instal machinery in the new power house at Swift Rapids. The present plant at Ragged Rapids generates 1,700 h.p., which is inadequate to the town's requirements, and some 500 h.p. is taken from the Hydro at its big chute plant. The town's new equipment at Swift Rapids will consist of two units of 1,600 h.p. each, and provision is made for installation of additional units up to 6,000 h.p., so that by retaining and operating its own generating plant Orillia will have ample power for its requirements for many years to come.

Prospecting for Natural Salts.—New regulations have been established by the Dominion Government to cover prospecting for salts of potassium in the region of the Peace, Athabasca and Mackenzie Rivers. It has been represented to the Interior Department that there is a strong possibility of discovering such minerals in this district and owing to the great demand for them for fertilizing purposes, and the fact that the present production is quite insufficient to satisfy the world's requirements, it has been considered advisable to make more favorable regulations. Prospecting for such minerals involves considerable expenditure and it has accordingly been provided that in the four Western Provinces and the North-West Territories rights to such minerals may be leased at a rental of 25 cents per acre for the first year and 50 cents per acre for the second year.

New Foundry Equipment Firm.—Leyshon & Lane, Incorporated, Detroit, Michigan, is a new company organized to take over the oven and special foundry equipment business which has grown out of H. M. Lane's foundry research work. The H. M. Lane Co. was organized some years ago to do foundry consulting work and to design new foundries. It was not the intention to make it a contracting or manufacturing organization, but various devices and



Standard 20-inch Drill Press

The Canadian Standard 20-inch Drill Press can be used for the various operations of reaming, sizing, centering, tapping, etc., on high explosive shells. It is adapted to meet the severe demands of shell manufacturers, and is fulfilling all requirements for specialized work.

equipment were developed, some of them being patented by H. M. Lane, particularly the forced draft core and mold oven system. Leyshorn & Lane, Inc., will contract for complete foundry installations, melting furnaces, annealing ovens, core ovens, mold ovens, and handling appliances. T. A. Leyshon, associated with H. M. Lane for several years, is president, and C. T. Holcroft, who has been enaged in furnace building for many years, is treasurer. The new company has made arrangements for a portion of H. M. Lane's time as consulting engineer. The H. M. Lane Co. will continue as a consulting organization.

New Incorporations

The Arnot Construction Co. has been incorporated at Toronto, with a capital of $40,000, to construct railways, tramways, docks, canals, etc. Head office to be situated at Toronto. Incorporators: D. Arnot, O. Rouse, and T. H. Peine, all of Toronto.

The Electric Fittings & Foundry has been incorporated at Toronto, with a capital of $48,000, to manufacture electrical machinery of all kinds. Head office to be situated at Preston, Ont. Incorporated by F. Charles O'Leary, of Toronto.

The Sure-Shot Mfg. Co. has been incorporated at Toronto, with a capital of $40,000, to manufacture polishes and cleansing materials, at Pembroke, Ont. Incorporators: G. A. Herron, of Westmeath, and F. W. Cockburn, of Pembroke, Ont.

Catalogues

Electric Motors.—Bulletin 102X published by the C & C Electric & Mfg. Co., Garwood, N.J., describes fully a motor which has recently been placed on the market. The motor is known as the "IB" type and is specially designed for direct connection to machine tools, fans and general industrial machinery. The principal features embodied in the design of the motor are described in detail while numerous illustrations give a general idea of the construction. Copies of this bulletin will be sent on request.

Direct Current Motors.—The C. & C. Electric Co., of Garwood, N.J., have published a bulletin, presenting their well-known direct current motor, known as the "Old Reliable." These motors are of the four-pole, interpole type, built in sizes from 1 to 125 h.p. The bulletin illustrates and describes the details of construction of the parts and contains a complete table of adjustable and constant speed ratings, with full dimensions of all frames.

Oil Filters.—Bulletin No. 5, recently issued by the Richardson-Phenix Co., Milwaukee, Wis., describes a complete line of filters for purifying lubricating oil, having capacities of from 25 gallons per day to 50,000 gallons per hour. This is a most complete oil filter catalogue and describes some exceedingly interesting large size filters for use in purifying lubricating oil from water wheel thrust

bearings, large gas and steam engines in steel mills, and also for purifying cutting lubricants. The catalogue serves to indicate the remarkable advance made in recent years in the science of oil filtration, and shows how scientific principles are employed in the small as well as the large size filters. The catalogue is profusely illustrated and contains prices on the various size filters. Copies may be had by addressing the company as above.

Iron and Iron-Carbon Alloys.—Bulletin No. 266 of the Scientific Papers of the Bureau of Standards, by Messrs. Cain, Schramm, and Cleaves, deals with the preparation of pure iron and iron-carbon alloys. The authors have worked out methods of producing laboratory samples of iron-carbon alloys of a very high degree of purity; sources of contamination of melts and means of eliminating them are described; a method of preparing magnesia of a satisfactory degree of purity for making crucibles to be used in work of this kind has been developed; and a procedure for making small ingots, which are sound and free from blowholes, without the use of deoxidizers, has been worked out. A series of iron-carbon alloys containing 99.96 per cent. of the two elements has been prepared to serve as a basis for the re-determination of the iron-carbon equilibrium diagram.

Book Review

American Handbook for Russia.—The American-Russian Chamber of Commerce, 60 Broadway, New York, of which E. C. Porter is secretary, has decided to prepare for exclusive distribution in Russia a handbook on American financial and commercial conditions, and containing a directory of selected American business houses. Hitherto American business firms have been unable to establish direct contact with Russian distributors and consumers, and Russian firms have had no means of developing direct connections with American business houses. The book, which will be printed entirely in Russian, will devote a section to a concise survey of industrial and commercial conditions in the United States. It will furnish general information in regard to commercial organizations, commercial laws and the details of the organization of American public utilities, railroads, mineral resources, etc. The publication has the official approval of the Russian Government and will be distributed by the Russian-American Chamber of Commerce in Moscow and its branch in Petrograd.

FOR SALE — ONE NEW FORD SMITH Grinder for Shrapnel. A short time ago we purchased five, find four will take care of our work. The National Manufacturing Co., Brockville, Ont.

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

1—C.G.E. TYPE 10—20 H.P. INDUCTION Motor—60 cycles, 220 volts, 45 amps.—1200 R.P.M., complete with Auto Starter. Pulley on Motor 12" Diam. x 10" Face. Cummer-Dowswell, Ltd., Hamilton, Ont.

FOR SALE—2—16 x 2 POWER FEED TURrets; 1—16 x 1½ Turret with threading attachments; 1—16 x 2 Turret; 1—16 x 8 Engine Lathe; 1—12 x 8 Tool Lathe; 1 Speed Drill. Apply J. A. Harvey, 16 Pearl St. (21)

FOR SALE OR RENT—MACHINE SHOP AND foundry, with garage. Good machinery, good locality. Lots of cars and boats. Power and rent very cheap. Box 334, Carleton Place, Ont. (21)

FOR SALE—ELECTRIC GENERATOR TO run 80 lamps, 110 volts, 300 r.p.m., including switchboard and indicator; in good condition. Richards-Wilcox Canadian Company, London Ont.

FOR SALE—COMPLETE MACHINE SHOP, fully equipped and working, in good city; low rent, cheap power; plant includes five lathes, Universal milling machine, grinder, etc. Will entertain partnership with practical man who has cash to invest, or sell outright. Box 201, Canadian Machinery. (21)

FOR SALE — COMPLETE LUMBER AND lath mill machinery, daily capacity seventy-five thousand feet, consisting of gang, single and double bandsaws, engine, boilers, etc. Fully equipped blacksmith and machine shops. Silsby fire engine, 2 streams of 2½ inch; good order. Log loader, capacity fifty thousand feet, ten hours; almost new. Exceptional manufacturing site bargains. Address The Rathbun Company, Deseronto, Ont. (18)

FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY
970 Queen St. West, Toronto (15)

FOR SALE

TWO ENGINE LATHES FOR SALE—ONE a 18" x 10' McKechnie & Bertram; the other other a double-end pulley lathe 18" x 10' between face plates; both ends completely independent; very suitable for cutting off base and open ends of shells. Turnbull Elevator Mfg. Co., Toronto. (22)

FOR SALE — TWO GOLDIE-McCULLOCH Wheelock Engines—cylinders 16" diameter, 38" stroke; both engines now running, but will be replaced with Hydro-Electric. Engines guaranteed to be in perfect condition, and will be sold complete with belt wheels, one 14' x 35" face and one 12' diameter with 24" face, also belting if required. Canadian Consolidated Felt Co., Berlin, Canada. (19)

PATENTS

THE PROPRIETOR OF LETTERS PATENT No. 126215, relating to "pump device," desires to dispose of the patent or to grant license to interested parties at reasonable terms, with a view to the adequate working of the patent in Canada. Inquiries to be addressed to the patentees, Aktiebolaget Ingeniorsfirma Fritz Egnell, Stockholm, Sweden. (21)

ELECTRODES — THE PROPRIETORS OF letters patent No. 127080, relating to "Process of manufacturing iron for use in alkaline accumulators," and No. 127081, relating to "Active masses for positive electrodes of electric elements, etc.," desire to dispose of the patents or to grant licenses to interested parties at reasonable terms, with a view to the adequate working of the patents in Canada. Inquiries to be addressed to the actual proprietors, Svenska Ackumulator Aktiebolaget Jungner, Stockholm, Sweden. (13)

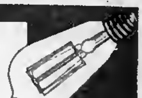
SITUATIONS VACANT

WANTED—FOREMAN TO TAKE CHARGE of Brass Foundry. Apply with full particulars. Box 203, Canadian Machinery. (21)

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month Box 184, Canadian Machinery.

MECHANICAL SUPERINTENDENT WANTed—for plant of the Starr Manufacturing Co., Limited, Dartmouth, Nova Scotia (near Halifax), operating one 10-inch and one 18-inch train of rolls, producing merchant bar iron. Manufacturers of ice skates and bolts and nuts. Address the company direct, stating age, experience, salary required, giving references, also when services will be available. The Starr Manufacturing Co., Limited, Dartmouth, N.S. (22)

WANTED



Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN LAMP FACTORY
ST. CATHARINES, ONTARIO

SITUATIONS WANTED

LARGE SHELL MANUFACTURERS — MEchanical engineer with shop, designing and executive experience with prominent Canadian quantity producer of 9.2". At present employed. Best of references. Address, in confidence, Box 200, Canadian Machinery. (21)

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

WANTED

WANTED BERTRAM WAVING ATTACHment for 4.5 Shells, with or without Lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson Limited. (R.T.F.)

WANTED—HYDRAULIC PUMP, GOOD FOR 2,000 lbs. pressure capacity for 16" diameter cylinder press; belt-driven preferred. Canadian Consolidated Felt Co., Ltd., Berlin, Canada. (18)

ENGINEER WANTS AGENCIES FOR MONTreal and district. Side line or specialties, on commission basis. X.Y.Z., Canadian Machinery, Montreal. (19)

WANTED — BERTRAM WAVING ATTACHment for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

BOILERS WANTED—TWO SECOND-HAND, about 150 H.P.; at least 80 pounds working pressure under Ontario Government Boiler Regulations. Give full particulars, Box 198, Canadian Machinery. (19)

INDEX TO ADVERTISERS

AN EXTERIOR IMPRESSION OF MONTREAL'S TECHNICAL SCHOOL.

The Montreal Technical School, Its Equipment and Service

Staff Article

In the brief space of some five years since establishment, the Montreal Technical School has amply demonstrated its worth as a developer of our national, commercial and industrial enterprise. A recital of the contributory factors which have influenced its achievement in these respects should, in consequence, be at once interesting and instructive, besides lending impetus to the movement for further installation of similar institutions within our borders.

IN the early days of modern engineering the opportunities of acquiring a knowledge of the principles of various branches, either from a practical or theoretical standpoint, were very limited, in comparison with those of the present time. The remark is often heard that "there are fewer possibilities for advancement now than years ago." This in many respects is a mistake, for while the achievements of the scientific world in the past quarter of a century have been exceedingly remarkable, the probabilities are that the next twenty-five years will surpass all previous records; and it is the boys and young men of today that we must look to for the accomplishment of these future developments, in all branches of science and engineering.

Before the advent of systematic training, the average boy was generally taken into a workshop without any previous knowledge of the duties he would have to perform; and his success, or failure, resulted largely in his ability to adapt himself to his new environment, aided possibly by the advice and instruction of one or two of his shop mates and occasionally the foreman.

The ideal system of training for engineering trades is by means of technical schools. Through these institutions, all classes of boys are given adequate and complete instruction in the various trades, both from a theoretical and practical standpoint, and the Montreal Technical School described in this article is a recent example of the perfection to which educational institutions of this nature have been developed.

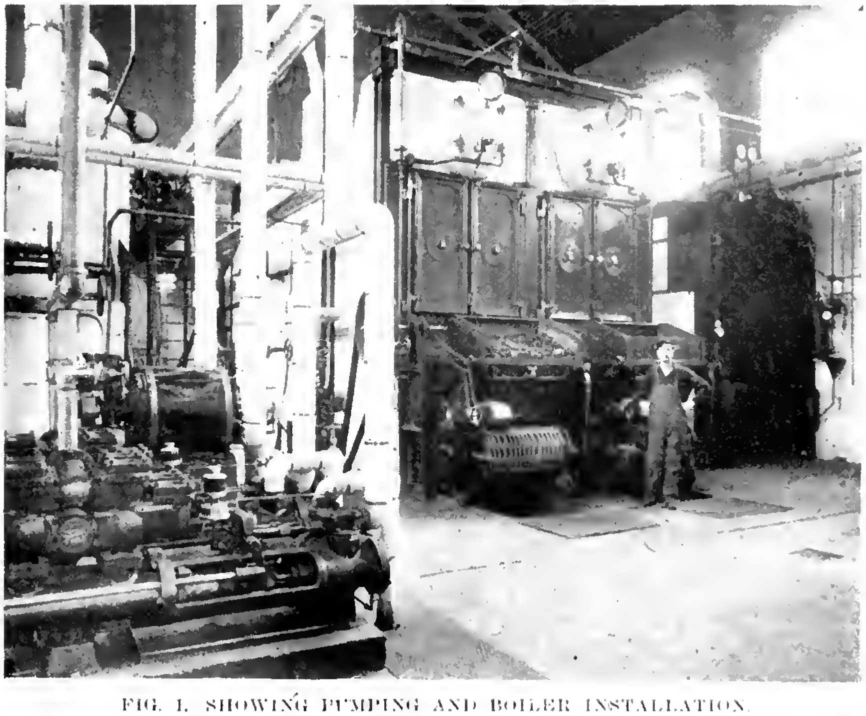

FIG. 1. SHOWING PUMPING AND BOILER INSTALLATION.

Main Building

This large commodious building, built and equipped at an approximate cost of $825,000, and annually subsidized by the Provincial Government of Quebec, with an additional yearly grant from the City of Montreal, was officially opened in 1911. The building is composed of two distinct sections, the main structure, which con-

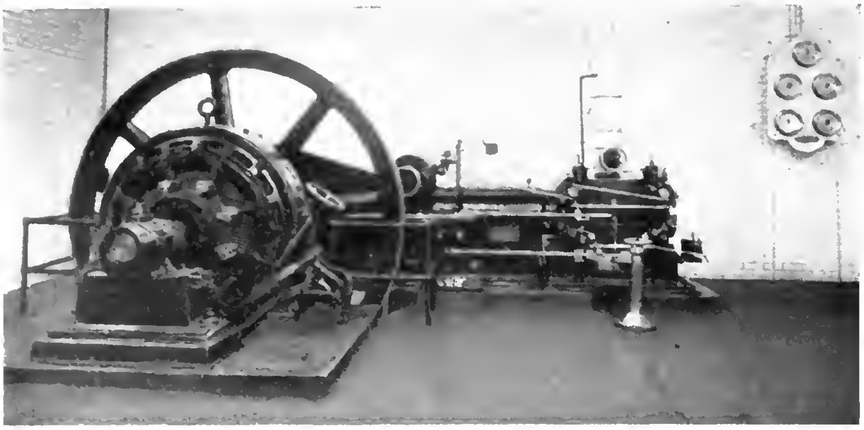

FIG. 2. CORLISS ENGINE AND GENERATOR OF 150 H.P. AND 125 K.W. RESPECTIVELY.

tains the administration offices, being located on Sherbrooke Street. In addition, there are several suites of class rooms for theoretical teaching, the various laboratories, two small amphitheatres to seat 100 each, one large amphitheatre with a seating capacity of 600, and a large hall.

In addition to requirements for instruction, the comfort of students is well provided for:—spacious and convenient waiting rooms, toilets and shower baths, appropriate furniture throughout, in fact, nothing has been spared to provide modern and efficient surroundings conducive to the success of the school as an educational institution, while from the viewpoint of comfort and hygiene, conditions approach the ideal.

Boiler Room

To the rear of the main structure are the power house and various work shops, all constructed along the lines of modern industrial practice. The power house, which is in the middle of the group consists of a boiler room, an engine room and a gas producer plant. The boiler room equipment shown in Fig. 1, consists of two Babcock & Wilcox 200 horsepower, water tube boilers, equipped with chain grates, operated by a Miller Bros. and Jones vertical engine; one Delaunay Belleville (French) marine type 100 h.p., hand fired boiler, with automatic regulated water feed, two-plunger type, Fairbanks-Morse pumps are used for the feed water, these are shown in the left foreground of Fig. 1. To the rear of the feed water pumps are two Kerr steam turbines, directly connected to two 24-inch centrifugal pumps, for supplying water to the forced hot water heating system, throughout the buildings. Two large Cochrane heaters are also installed, so arranged that one is supplied with exhaust steam from the

FIG. 4. PRODUCTS OF THE SCHOOL FOUNDRY, FORGE, AUTOGENOUS WELDING AND MACHINE SHOPS, ETC.

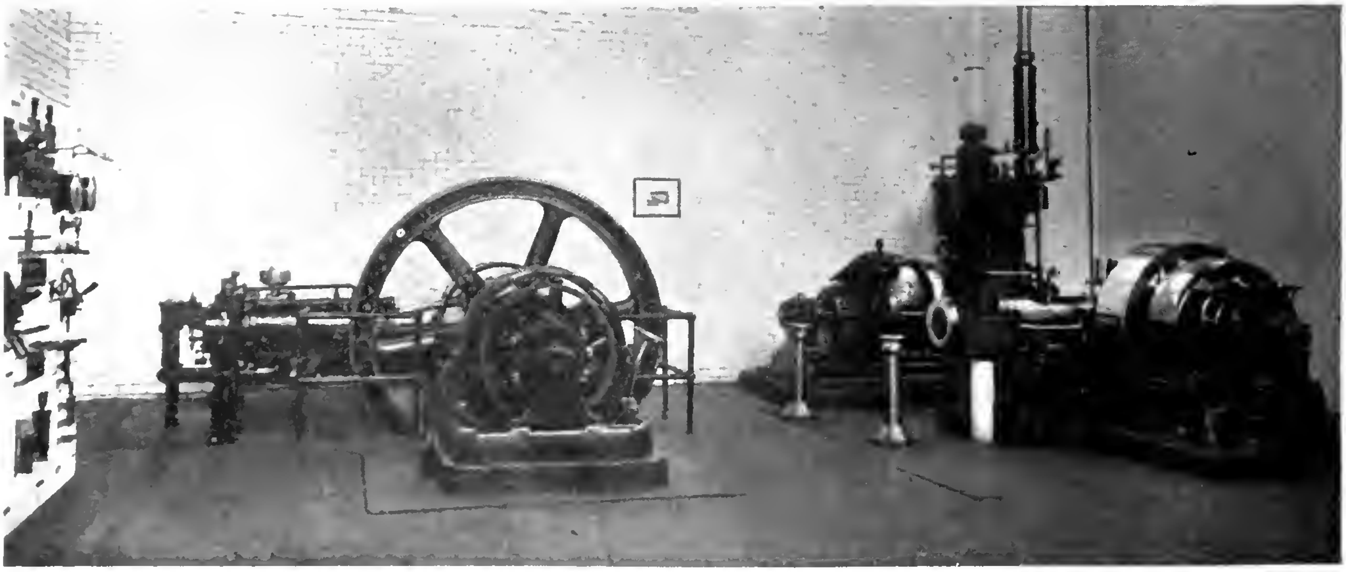

FIG SHOWING 35 H.P. HORIZONTAL GAS ENGINE, 35 H.P. HORIZONTAL STEAM ENGINE, AND COMPOUND VERTICAL STEAM ENGINE, DIRECT CONNECTED IN EACH CASE TO GENERATORS.

engines and the other with live steam from the boilers. In the event of insufficient exhaust steam being available to heat the water to the desired temperature, an automatic system of control operates a valve and allows the water to pass through the live steam heater before passing to the heating apparatus throughout the building.

FIG. 6. THE FORGE AND BLACKSMITH SHOP.

Heating and Ventilating System

An interesting feature of this installation is the utilization of every pound of exhaust steam for heating purposes before the addition of live steam becomes necessary and the consequence absence of back pressure on the engines. This system is so satisfactory that the return water after heating is only a few degrees below that of the outgoing or heated water. The large ventilating fans and steam coils are regulated by the Powers system of automatic temperature control.

FIG. 5. CARPENTER, JOINER AND PATTERN SHOP.

An allowance of 30 cubic feet of fresh air per minute is provided for each pupil with a liberal additional amount of ventilation in all class rooms and workshops.

A complete vacuum cleaning system is installed, with connections at convenient locations throughout the entire building.

Engine Room

In keeping with the general policy of instruction and at the same time to provide the necessary power equipment for the building the engine room units are of various, but modern types. The largest unit is that shown in Fig. 2, which is a 150 horse-power Goldie & McCulloch Corliss engine, direct connected to a 125 k.w. Allis-Chalmers-Bullock generator. The other three units are shown in Fig. 3. In the right background is shown the 100 horse-power vertical compound, Belliss and Morcom engine, equipped with forced lubrication system, and direct connected to 75 k.w. Westinghouse generator. Directly in front of this is seen the Robb-Armstrong 35 horse-power horizontal engine, direct connected to a 35 k.w. Canadian Crocker-Wheeler generator. To the left is shown a Duplex (French) 35 horse-power gas engine direct connected to a 25 k.w. Canadian General Electric generator. This unit is operated with producer gas, obtained from a small plant in the adjoining room. This consists of a Pierson (French), gas producer, with scrubbing and cooling equipment which delivers clean gas at a suitable temperature for use in the engine. A suction fan operated by a Robbins & Myers motor is used to start the gas producer. To operate the Duplex engine it is necessary to start with compressed air, which is supplied to a reservoir at a pressure of 175 lbs. per sq. inch. After the first stroke the gas is drawn into the engine and automatically regulated acording to the load.

In addition to the gas producer this room contains an Ingersoll-Rand air compressor for supplying high pressure air for pneumatic tools, etc.

It might be stated here that practical lessons on the construction and operation of gas and steam engines are given to engineering students by their class

FIG. 7. THE GREY IRON FOUNDRY.

FIG. 9. VIEW IN MACHINE SHOP.

instructors, aided by the engineer of the power house; in addition to which there are numerous models, in section, of feed water pumps, injectors, and many engine room accessories from which the pupils are given personal instruction.

Main Switch Board

The engine room switch board consists of seven panels of polished white Italian marble. The feeder panels from which radiate the various primary circuits contain a Bristol watt-hour meter for recording total station output, and three double pole plain overload circuit breakers. Knife switches, with enclosed fuses on the face of the board, control the lighting feeders. The accumulator panel is equipped with meters, overload breaker, a battery rheostat and an eleven point end cell switch. The generator panels are fitted with Weston flush-type ammeters, with a range of 150 per cent. of generator output; and three-pole knife switches with fuses on the rear of the board.

A voltmeter, located to the extreme left of the main switch board, and supported on a swinging arm, can be made to indicate either the bus bar voltage, the voltage of any machine, or the drop of potential between the bus bars and the ground.

Wood Working Shop

A fully equipped wood working department, with an area of 6,810 square feet supplies ample facilities for thorough instruction in carpentry, joinery and pattern-making. The machine equipment comprises eight power wood-turning lathes, four motor driven lathes of variable speed, one each, band saw, circular saw, jig saw, buzz planer, pony planer, mortising machine, tenoning machine, drill, shaper, trimmer, automatic band saw filing and setting machine, band brazer, and two grindstones; 30 benches, part of which are shown in Fig. 5, are also provided each with two separate sets of tools, one for the day and the other for the night classes.

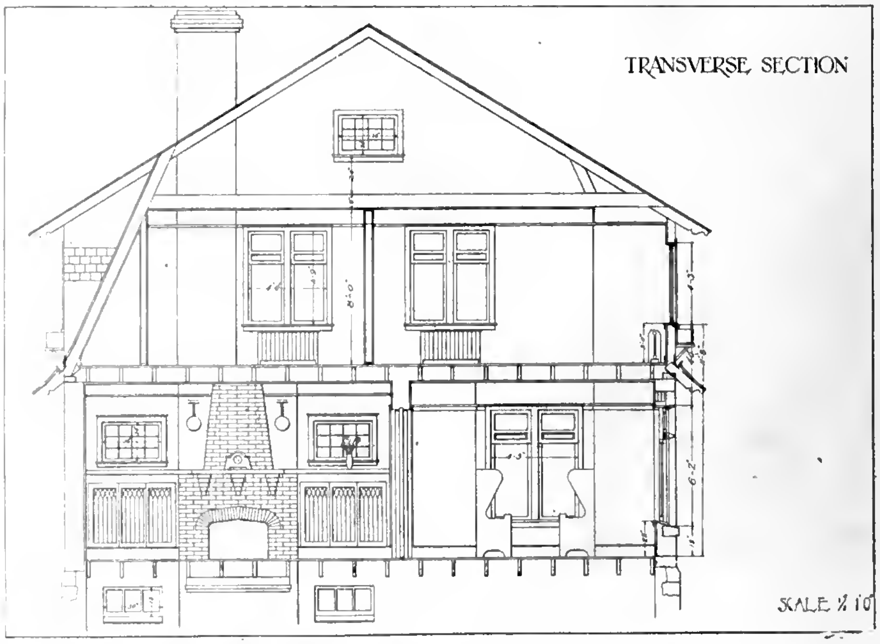

FIG. 10. SUBURBAN HOUSE—WORK OF A THIRD YEAR STUDENT.

FIG. 8. ELECTRICAL WORKSHOP AND ELECTRO-DYNAMIC LABORATORY.

Foundry

This department has a total area of 5,210 square feet and all the castings used in the various workshops are made here by the pupils, with the aid of the instructor. The equipment consists of a 2-ton per hour King cupola, one oil melting furnace, underground installation of compressed air for operating elevator and pneumatic tools and machines, two moulding presses, two core ovens, one core machine, one coning machine, one sand shifter, one sand mill, two snagging wheels, one torch heater and moulding benches for 24 pupils. Two 1-ton traveling chain blocks are used for transferring castings and material.

Forge Department

This section has a total floor space of 5,210 square feet and contains 24 Sturtevant forges, operated by forced blast supplied through underground piping from a 24-inch fan direct connected to a Sturtevant Co. four horse-power motor. A large 4-foot fan operated by a 9-horse-power electric motor is used to draw the smoke and gases from the fires and exhaust the same through the roof. This equipment is shown in the top background of Fig. 6. An anvil is supplied with each forge, and in addition there is one case hardening and tempering furnace, 30 inches square, supplied by the Buffalo Forge Co., one 170 lbs. steam hammer, made by Vulcan Iron Works, one Plessisville Foundry 75 lbs. spring hammer, one McGregor Gourlay Co. shear, and two swage blocks, two blacksmiths' vises, one tool bench and vise, and a plentiful supply of tools for each fire.

FIG. 12. AUTOMOBILE CHASSIS CONSTRUCTION AND ASSEMBLY.

FIG. 11. ANOTHER VIEW IN MACHINE SHOP.

Electrical Section

Directly adjoining the machine shop is the electrical work shop and electro-dynamic laboratory; the former containing one armature banding and heading machine, one notching press, one shear, one pair smoothing rolls and one buffer. In the laboratory are five groups of induction motors, one single-phase synchronous motor coupled to a direct current dynamo; one direct current motor coupled to a three-phase generator; one compound wound generator, one six-change commutator and one direct current motor coupled to an alternator. A large seven-panel switch board, fully equipped for experimental and operating purposes is also provided. There is also a switch board for telephone instruction, and a storage battery having a capacity of 200 ampere-hours.

Machine Shop

The large and modern machine shop, with a total floor area of 11,340 square feet, offers excellent facilities for thorough and efficient instruction in machine shop and tool room work. As shown in Fig. 9, the shop if of extensive proportions, well lighted and equipped with a large number and variety of different types of machines. All instructors have had many years of practical experience and are well qualified for their positions.

The machine tool equipment is divided into three sections, each section being driven by a 15-horse-power Croker-Wheeler motor. The machines installed are:

Drills.—One American Tool Works, 3-ft. radial; two 20-in. Rockford; two 16-in. W. F. & J. Barnes; two 16 in. Hoefer; four 12-in. Rego; one 10-in. Freeport; two 10-in. Hamilton Machine Tool Co.; one Washburn drill grinder.

Shapers.—Three 12 in. F. Pratt & Co.; one 16-in. R. A. Kelly.

Planers.—One 2 x 2 x 5 ft., and one $2\frac{1}{2}$ x $2\frac{1}{2}$ x 7 ft R. Gardener & Sons, Montreal.

Lathes.—Ten 10-in. Seneca Falls speed lathes; two 12-in. Seneca Falls; four Jones & Burton 10-in. gap; one Flather 15-in.; one Springfield 15-in. motor driven; three Fay & Scott 16-in. motor driven; one C. M. C. 18-in.; one Reed 18 in.; one Seneca Falls 14 in.; one Cisco 16 in.; one Von Wyck 18 in.; one Hendey 16-in. special lathe; and one Hare 6-ft. face plate lathe.

Milling machines.—One Brown and Sharp universal; one Jones & Burton horizontal; one Becker vertical; and one Greenwood & Batley vertical.

Miscellaneous.—Two Whiton centreing machines; two Greenerd arbor presses; one Becker automatic gear cutter; one Binsse horizontal boring machine; two screw-cutting machines; one Hartford automatic screw machine; one 7-in. slotting machine; one pantograph; one Columbia winding machine; one set 4 x 30 in. Brown Boggs forming rolls; one Max Ames power press; one profiling machine; one 36-in. Brown Boggs

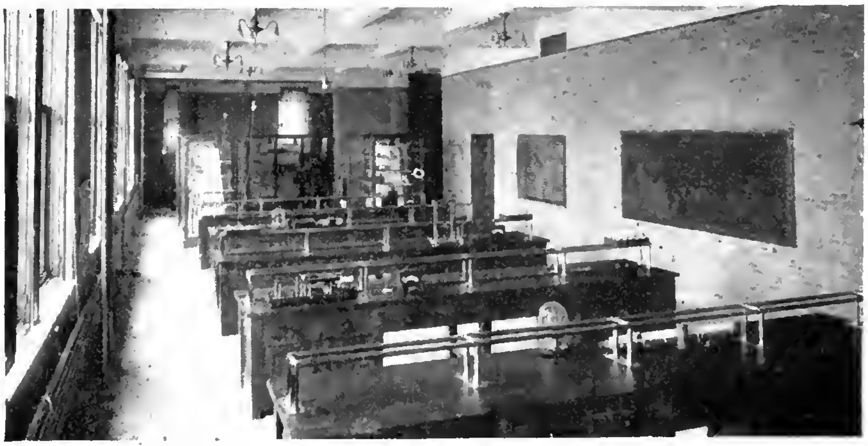

FIG. 13 PHYSICAL LABORATORY.

shear; one Norton universal grinder; two Montreal Technical School hack saws; two J. G. Blount grind stones and two 12-in. emery wheels.

In a seperate room are two Stewart furnaces for hardening and tempering tools and dies.

Oxy-Acetylene Welding

In a separate room are two Stewart being made in the use of the blow pipe for cutting and welding purposes, the authorities of the school, at the opening of season of 1914-15, started a night class on the uses and operation of the oxy-acetylene method of autogenous cutting and welding. This latest branch of technical education has met with very encouraging success. Some of the results of the first year's work are shown on the right hand table and wall panel illustrated in Fig. 4. This department is under the direct supervision of the "L'Air Liquide" Society.

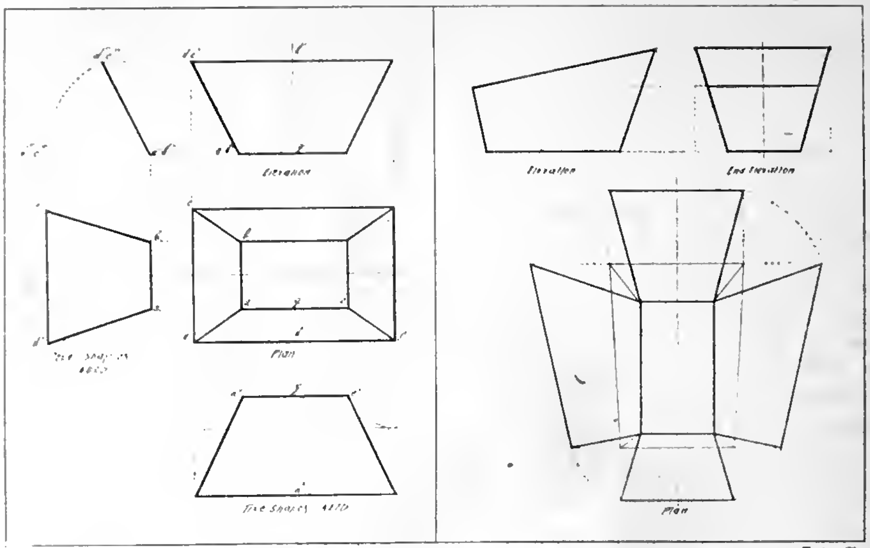

FIG. 15. RABATMENTS—WORK OF A FIRST YEAR STUDENT.

FIG. 14. EXHIBIT OF STUDENTS' WORK.

Industrial Drawing

In keeping with the high standard maintained by all the other branches, that of mechanical and architectural drawing has yielded very encouraging results. The boys receive instruction from the simplest form of free hand sketching, on through the various sections of elementary geometry, projection and development of surfaces, sketching from models and machines and assembling the same from the free hand sketches previously taken. That the work is of the best, can be shown by referring to the line reproduction here shown of the work of some of the students, whose average does not exceed sixteen. The work showing the transverse section of a dwelling and the details of the Roman Corinthian was accomplished by a boy seventeen years of age.

During the third year, pupils are permitted if they so desire to take detail sketches of operating machines in the shop and assemble the same as shown in the line cut of the slotting machine.

Rules and Duration of Classes

This school offers day courses for regular students, from September to June, and night courses from October to March; the latter intended primarily for workmen and apprentices at work during the day in the various manufacturing and building trades. As the school is not self-supporting a reasonable fee is charged for both the day and night classes; but in the case of boys wishing to take up a day course and not in a position to finance the same, provision is made whereby it is possible for almost any young man to receive the required tution, at practically little or no expense.

The day courses are organized principally for the benefit of young men, who, having recently finished their primary or elementary studies, are anxious to acquire manual proficiency, and the technical education necessary to become skilled mechanics, capable foremen or shop superintendents.

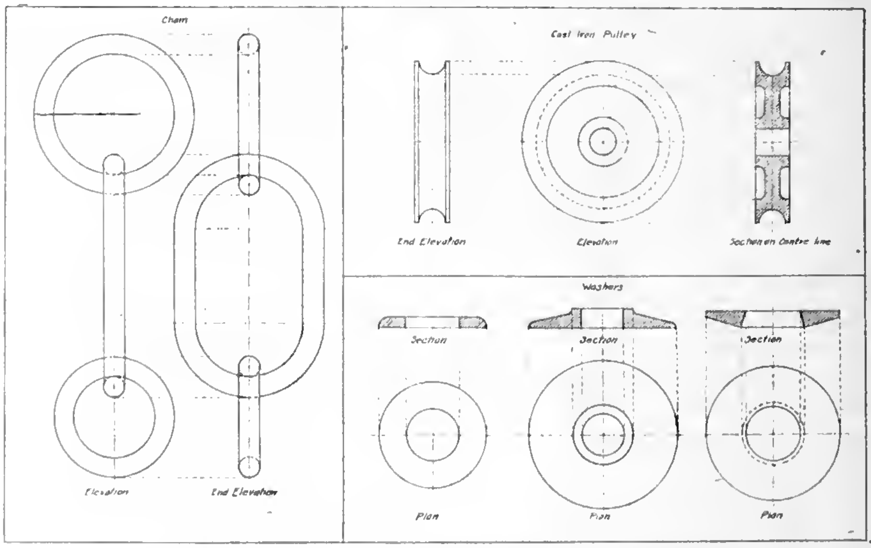

FIG. 16. PROJECTIONS—WORK OF A FIRST YEAR STUDENT.

As the school is situated in the Province of Quebec where the population is largely French, the day courses are given in two languages, consequently the pupils are divided into two distinct groups, for class or theoretical instruction; but both sections are united for practical work in the various shops.

Both the theoretical and practical instruction are very thorough; the former covering arithmetic, algebra and trigonometry, elemental and descriptive geometry, general and industrial physics, electricity, general and applied mechanics, drawing in all its branches and industrial technology.

Unless a boy has definitely decided on a future course, the first year at the school is for the purpose of finding out the qualifications of each boy for certain branches of engineering activity. While a young boy may feel he would like to take up a certain line of work, it is often found that his gifts and inclinations can be developed to far better advantage in some other lines.

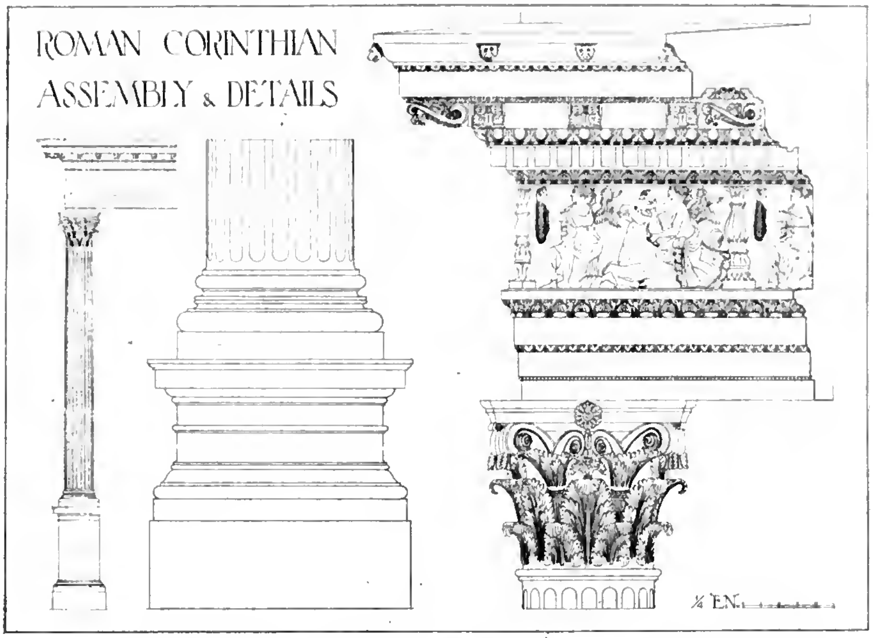

FIG. 18. DECORATIVE ORNAMENT—WORK OF THIRD YEAR STUDENT.

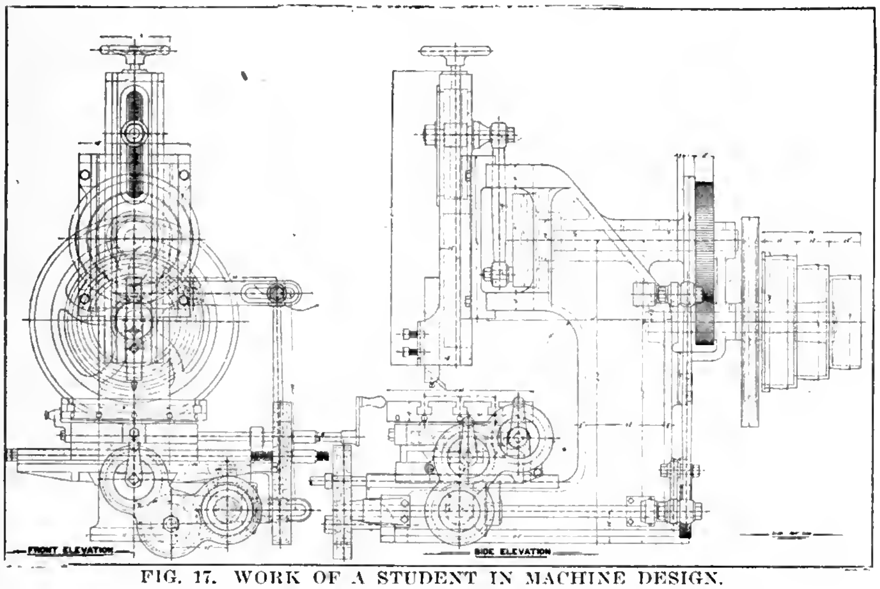

FIG. 17. WORK OF A STUDENT IN MACHINE DESIGN.

While certain rules govern the course of the boys through the various classes, a reasonable amount of latitude is given to each pupil to develop his individual initiative. With this method it has often been found that a dormant mind has been awakened from a state of indifference to one of marked activity.

The normal duration of each course is three years, but those students who have passed satisfactory examinations and been granted diplomas, may, if they so desire, and are duly qualified, take an additional year in advanced work, or to specialize in some one branch such as electricity, industrial drawing, automobile construction, etc.

Results of Instruction

It is very difficult to convey to the readers any definite conception of the achievements of these pupils, as it would be necessary for one to view the work at close range to fully appreciate the remarkable results obtained in the various branches of the school. However, some idea can be conveyed, to the uninitiated, by referring to Fig. 14, which illustrates a section of the exhibition hall. With the exception of the covers on the tables every visible object was constructed by the pupils, and when it is considered that the average age of these boys will not exceed sixteen years, the ultimate result of a few years training is very obvious. The work here exhibited surpasses, in many respects, that of a large number of journeymen mechanics now working at the various trades. A closer view of some of the work is shown in Fig. 4. The left hand panel contains some of the work of the first year pupils in foundry work, while the table display is that of second and third

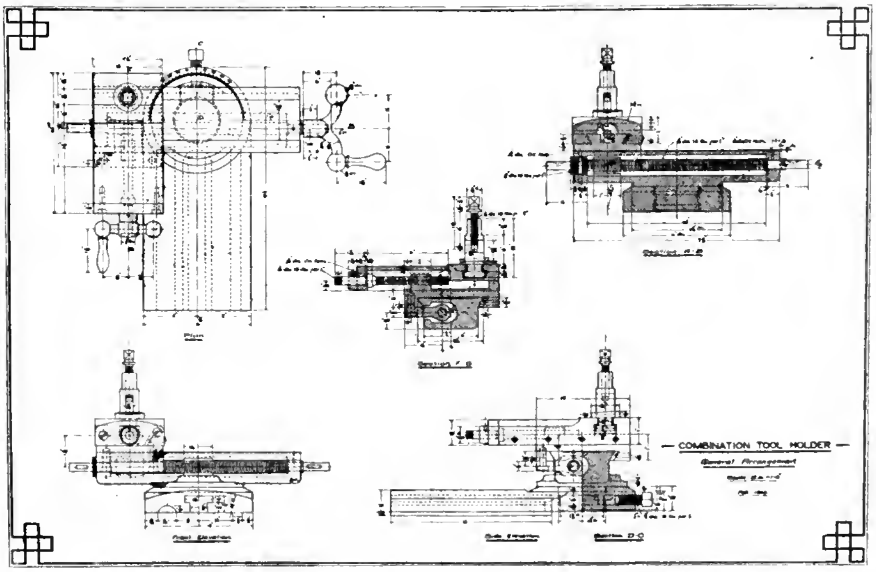

FIG. 19. WORK OF A STUDENT IN MACHINE DESIGN.

year students. The centre panel and the objects directly below illustrate some of the work performed by pupils in forging; while the work to the right is that of the oxy-acetylene department. In addition to the work here shown are several large show cases containing some of the finer work of the machine and electrical classes.

QUEENSLAND MINERALS AND THE WAR

IN Queensland we have rich deposits of molybdenite, wolfram, and such metals as are required for the manufacture of steel. With such an abnormal demand for high-grade steel for munitions of war as exists at the present time, why cannot these deposits of molybdenite and wolfram be worked? says a Queensland paper. The cry in the past has been that the profits allowed by the metal combine are so infinitesimal as to make the working of the mineral unprofitable, in view of the fluctuations on the market. This cannot now be said, and with molybdenite at £525 awaiting those willing to undertake the work. The output of molybdenite this year has been considerably increased, but even then only a few hundred tons have been extracted. The production during the coming year should at least be trebled. Some of the mines are now working for the extraction of this mineral, but a lot more could be done. The Government has decided to establish a State battery for the treatment of molybdenite in the Herberton and Chillagoe districts, and it is now in course of erection.

EMPLOYMENT OF WOMEN IN GERMANY

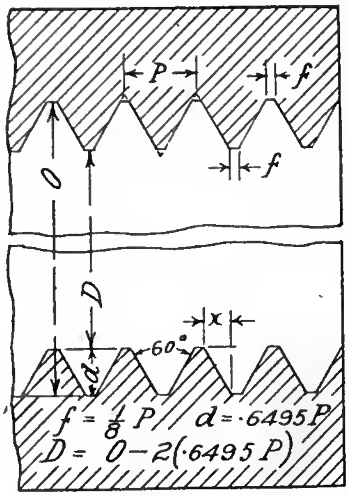
THE number of persons engaged in German industries in January, 1916, was about 9.3 per cent. below the peace-time average. The greatest increase is in mining and in the chemical, iron, metal and engineering industries, but only in so far as the works affected are making war material. This is indicated in a review of the labor market in the German Empire in January, 1916, published recently by the Government and based on reports from 39 industrial associations and 442 business undertakings. Of the latter, 362 firms employed an aggregate of 312,105 hands, compared with 270,148 in January, 1915. The increase consists almost entirely of women, the men employed being only 11,000 more than a year ago and made up largely of prisoners of war or inhabitants of occupied territory.

Some machine men run belts entirely too tight, causing a large increase in friction in the bearings, thereby consuming extra power.

Questions and Answers

Question.—Without the use of a table how can the bore of a hole be calculated for the standard United States thread?

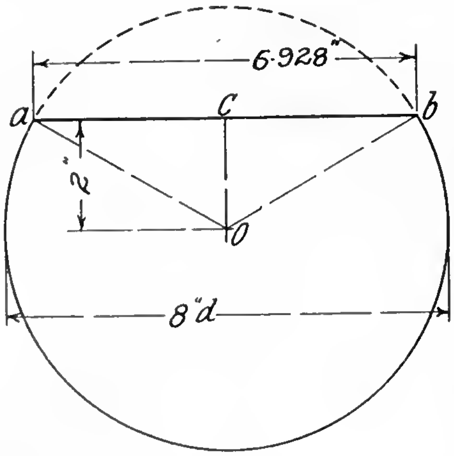
Answer.—As shown in the sketch, the flat on the top and bottom of the thread



is equal to 1/8 of the pitch; therefore, the distance x will equal the pitch minus twice the flat or 1/4 of the pitch. Then to find the depth use the formula, side adjacent = cotangent × side opposite, or 1.73205×3/8P; for example, to find the bore for a 4-inch diameter, 3-thread U. S. screw. The depth would be 1.73205 × 3/8P, or 1.73205 × 3/8×.333 = .2163 inch. Then bore would be 4 — (.2163×2) = 3.5674 inches. From the above a formula may be derived which will simplify the operation, thus—1.73205×3/8P = .64952P, which multiplied by two will give the total amount to be deducted from the diameter of the bolt or male thread.

* * *

Question.—A sphere 8 inches in diameter is to be shaped off to form a



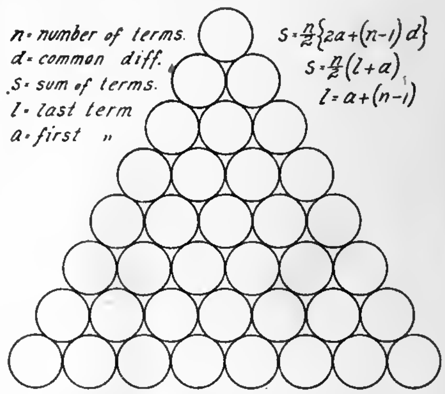
flat surface 2 inches from the centre; what will the dimensions be of the exposed surface?

Answer.—It is quite evident that the surface will form a circle; then to find the diameter, use the formula for the solution of right triangles; that is, the square root of the sum of the squares of the two sides will be the length of the hypotenuse. Therefore, the length c-b will be $\sqrt{(ob)^2 - (oc)^2} = \sqrt{4^2 - 2^2} = \sqrt{12} = 3.464$ inches. Then the diameter a-b of the exposed surface will be $3.464 \times 2 = 6.928$ inches.

* * *

Question.—When shafts are piled, as shown in the sketch, is there any method whereby the total number can be calculated besides counting them? If there are fifty in the bottom row, and each row upward is less by one, how many would be in the pile; and, if instead of reducing by one, the rows reduced by two or more, what would be the total?

Answer.—This can be solved by arithmetical progression, where n equals the number of terms, d equals the common difference, s equals the sum of the terms, l equals the last term, and a equals the



first term; then the above question can be solved from the formula $s = \frac{n}{2}(l+a) = \frac{50}{2}(50+1) = 1275$. To solve for s from the accompanying sketch, $s = \frac{n}{2}(l+a) = \frac{8}{2}(8+1) = 36$.

Suppose instead of being piled to the top, there was only 5 rows, the value of s or total shafts would be $\frac{n}{2}(l \times a) = \frac{5}{2}(8+4) = 30$.

Now, if the rows reduced by 3 from the bottom row, the top row containing 8 and the pile fifteen rows deep, the total would be

$$s = \frac{n}{2}[2a + (n-1)\ d] = \frac{15}{2}[2 \times 8 + (15-1)\ 3] = 435$$

EFFICIENCY IN THE ENGINEERING BUSINESS

By "Onlooker"

THE matter of power is apt to be overlooked to some extent in most industries in which it plays a part, and although in the engineering world it gets, perhaps, a greater degree of attention than in many others, it does not get quite all the attention it deserves. It has been estimated that in all industries the average percentage of the total cost of production which is expended in the generation of power is only about six per cent. The writer ventures to think that under existing circumstances this is a low estimate, at least as far as the engineering industry is concerned, in which ten per cent. is probably nearer the actual figure when all factors are taken into consideration. At the same time, given power plant of an efficient nature and modern distribution methods, there is no reason why the cost of power should exceed five per cent. of the total running costs of any plant, while under favorable conditions it may be considerably less. And in these days of modern competition cheap power may just be the factor which forms the dividing line between a profit and a loss.

Favorable Power Supply

In this country the majority of engineering concerns are fortunate in the matter of power. Located for the most part in industrial centres which are supplied with hydro-electric power at low rates, the power problem is largely solved. Electric power is of all forms of power the most adapted to the engineering shop, and where this is available at reasonable rates from public mains the difficulties of an economical power supply are reduced to a minimum. Yet even in such favorable circumstances a study of economy is advisable, as it is a profitless thing to run up unnecessary power bills. Where cheap current is available a system of distribution giving the most efficient results should be adopted, and in order that this may be accomplished several considerations must be examined. In the first place small motors are generally less economical by an appreciable amount than larger ones, and therefore a large number of very small power units are wasteful in current and are also more expensive to install and run up bigger bills for interest on capital invested and depreciation than a few larger units. On the other hand where a whole shop is run by a few large power units there is a big loss in friction, due to the necessary mechanical transmission, which becomes particularly pronounced when only a few machines are being operated, as often happens during small night shifts or when only a few machines are being operated. Between the two extremes of a whole shop being driven from a single high power motor and that of an individual motor to every machine there is a happy mean course which probably gives the best results. It is to have the larger machines, requiring 15 horsepower and upwards, driven by individual motors, and the other machines grouped in twos, threes, fours or fives, depending on their size, and driven from a common shaft operated by a motor of suitable size. By this method the loss in efficiency due to the use of very small units is largely avoided, while if only a few machines are required to operate at a given time, after the rest of the shop is closed down, it will not be necessary to run the whole of the shop shafting, with its accompanying heavy loss by friction, in order to do so.

Prime Mover Choice

Where public hydro-electric power is not available at a reasonable rate it will usually be advisable to generate power on the premises, and distribute electrically through motors along the lines indicated previously. Of prime movers the choice will usually rest between natural gas, where this is available, steam plant with coal or natural gas firing, and pressure or suction producer gas plant. Whichever of these forms of power is advisable must depend upon the location of the plant. Where good steam coal is easily obtainable, a modern steam plant will probably give the best results, owing to its reliability, and even where natural gas is found it may frequently be advisable to adopt a steam plant fired by gas. Where the only available supply of coal is soft a producer plant will give excellent results in so far as economy in fuel and attendance is concerned, but unless this description of plant is of first class design and cared for by men who thoroughly understand it there is a possibility of occasional breakdowns which may hold the whole plant up for considerable periods and involve losses which its economy will fail to compensate for.

Electrical Energy Feature

Whatever form of prime mover is adopted it is generally good practice to convert the mechanical into electrical energy and to distribute it in the manner indicated above. Direct mechanical transmission is often very uneconomical. Of the gross power developed in the cylinders of an engine it is safe to say that, where mechanical transmission is employed, an average of nearly fifty per cent. of that power is absorbed in friction in the engine, the shafting and belts, while with electrical transmission this loss is reduced to about twenty-five per cent., or even less. In one case which came beneath the writer's own notice no less than seventy-five per cent. of the gross power developed by the engine was absorbed by the mechanical transmission, and this represented a cash loss to the company of no less than $3,000 annually, although the plant was only of 100 i.h.p. This was an exceptional case, but it demonstrates how neglect of power matters may involve a very considerable leakage.

Another argument in favor of electrical distribution where mechanical generation is employed is the gain obtained when only a few machines of the plant are operating on a rush job during the evening or night. Where mechanical power distribution is employed this means that the attendants have to be retained to run the power plant and also that a great deal of the power generated is wasted in running shafting useless save to transmit the power of the engine to that part of the shop where the machines to be operated are located. Where electrical distribution is employed, on the other hand, the addition of a few storage batteries to the plant will enable the engine to shut down at the usual time, the machinery being run by stored energy, and all the shafting which has to be run is that length upon which the particular machine is located. This saves loss of power by friction and also the expense of paying overtime to the engine attendants.

Individual Motor Drives

Individual motors on larger machines are always to be recommended. These are now made so that they operate efficiently over a wide range of speeds, and thus gearing is done away with and a more finely graduated range of speed rendered possible. This last consideration is worthy of notice. There is one speed at which any given piece of work can be machined at a maximum efficiency, and where there are only four, or even eight, speeds on a machine it is not always possible to adjust that machine

to the ideal speed. The more speeds there are on a machine the more nearly may it be adjusted to the best possible speed for any given piece of work, and the finer adjustability of the variable speed motor as compared with the mechanically driven tool gives the former a big advantage for this reason.

The cost of installing electrical for mechanical transmission is not very great, while the results obtained may be very great indeed. Where an engineering works is scattered, or is very large, or where it is frequently found necessary to keep a part of the machinery running after regular hours in order to keep up with the work, it will almost always be found that the saving effected by changing from mechanical to electrical transmission will be found to be a paying investment.

Shafting Roller Bearings

A point in power transmission which is worthy of attention is the growing use of ball or roller bearings in place of the older bushed types. Where shafting is employed, whether it be in relatively short individual lengths in case of electrical transmission or in longer units where mechanical transmission is employed, a considerable saving can be effected by adopting ball or roller bearings. Of course this saving is much more marked in the latter instance, but is not negligible even in the former. In one case, which recently came beneath the writer's notice, a certain shop found it necessary to install quite a number of extra machines in order to cope with growing business, and when these and their shafting had been put in it was found that the engine could no longer handle at normal speed the increased load. The management was reluctant to have to install new or additional steam plant at that time, and solved the problem by changing the old bearings for ball bearings. Several other machines have been added since then but the old steam plant is still capable of running the whole shop at normal speed. Whether it would not have been better to have changed from mechanical to electrical transmission is a question, but as the shop in question was not very large, and was built on a compact plan it is probable that the ball bearings gave just as good results as electric motors would have done.

SHELL MAKING TOOLS

By Henry McLaren.

I NOTICE in your journal of April 13, an article signed by "W. J. M.," who is very sorry for the designer of the shell chucks illustrated on page 311 of your issue of April 6; in fact he appears to be very sorry for the Old Country engineers in general.

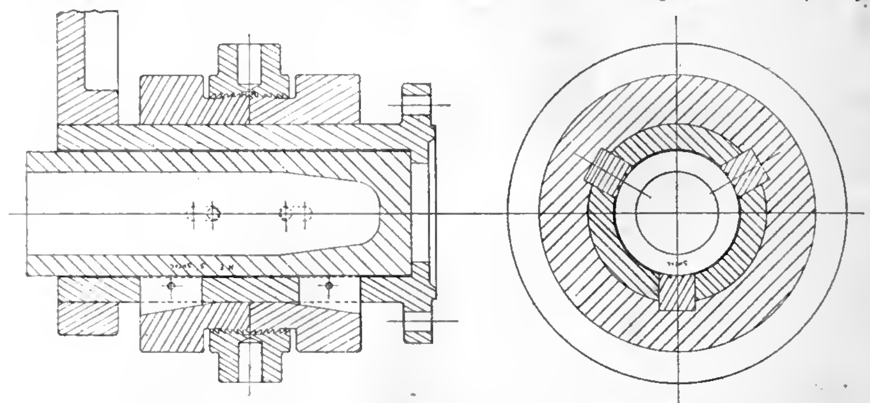
I am the designer of the said chucks, but I have no time to waste on "W. J. M.s" criticisms. He has evidently been misled by the description in the "Engineer," for which I am not responsible. Our collet rings are not coned, as "W. J.M." supposes; I think that must be an invention of the "Engineer." We sent them a copy of our catalogue and book of instructions some time ago. These instructions are illustrated with diagrams, to enable any mechanic (who is supposed to have the chuck before him) to dismantle or assemble it with the least possible trouble. The "Engineer" picked out one or two examples and published them. These diagrams were not intended to clearly set out the merits of the chuck, they were simply an aid to a man who had the fixing of the chuck; therefore I don't blame the "Engineer" for saying the collet rings were coned. If he had seen a working drawing of the chuck he would have known more about it, and have saved me from the wrath of "W. J. M."

The "Engineer" also says my firm is "J. & H. McLaren, Limited." I beg to correct him; we are unlimited, and my capacity for slacking, and my horror of letter writing, is the most unlimited feature of our concern.

I therefore send you a copy of this book of instructions, along with a drawing (No. 6499) of our chuck attached to the boring lathe you illustrate on page 331, and I leave it to you or your readers to decide whether or not it is a judicious mixture of common sense and cast iron.

From this drawing you can see that the collet rings have tapered slots cut in them, to take the jaws. The rings and sleeve are bored, turned, and ground, to absolute sliding fits. The large nut, with right and left hand screws, forces these rings apart, and they in turn wedge the jaws in against the shell. Whatever pressure is applied to one set of jaws must react on the other set with exactly the same pressure. Each ring is fitted with three jaws, therefore, the pressure is distributed equally between the six jaws; even if the job is different diameters in each set of jaws, they will still nip down with equal pressure on all them. The jaws are arranged to take a long hold of the shell, and as explained in our book, the jaws, after hardening, are all ground out true in place.

"W. J. M." expresses surprise that our machine shop should be wholly occupied in making these chucks. He cannot be more surprised than we are, for although we have been running night and day—including Sundays—for the past year, during which time we have made many thousands of these chucks, the demand is as great as ever, only it



DETAILS OF CHUCK REFERRED TO BY HENRY McLAREN.

is for chucks for the larger sizes of shell.

"W. J. M." is not content to remain as critic, he must try his hand at designing. On page 329, Figs. 1 and 2, we have his productions. I only make one criticism. In Fig. 2, when he gets even a moderate pressure on the jaws, how is he going to turn that nut? I think Fig. 2 might prove a success as a nut-locking device, if it does not prove a success as a chuck; but I am afraid the coned face inside the nut will be soon cut out by the jaws. A word in your ear, Mr. W. J. M., where you have great pressure, avoid movement as much as possible, and the job may last out the war.

I might write a chapter on each of his designs, but will spare your feelings. I note the remarks of "W. J. M." on pot chucks with draw in collets, also I see an ild friend in the adapter centre he illustrated on page 330—we have made them both. I feel tempted to explain one or two things about them to "W. J. M.," but alas I am now completely exhausted.

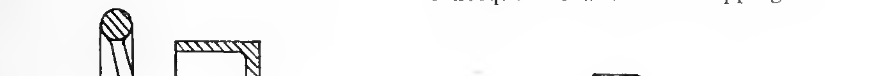
SHELL MAKING TOOLS

By W. J. M.

THE letter from Henry McLaren in reply to my criticisms of his chuck in your issue of April 13, has explained several points, uncertainty regarding which prompted my communication. The illustration and description of Fig. 1, page 311 of Canadian Machinery, gave me the impression that the ring D was a hollow cone which fitted at its smallest diameter on the chuck body A. Had the front end of ring D been shown

slightly ahead or back of the end of jaw E it would have been clear at once that ring D had a parallel bore for its full width, and was provided with inclined grooves to fit the outer edge of the jaws. The greatly increased wearing surface thus available between the ring and the chuck body removes the objection which I raised, viz., that after severe service the ring and the jaws would be floating and held in position by friction only. The use of the term "conical collet" in the original article is not correct and conveys a wrong idea.

The rough sketches submitted by me are certainly open to criticism on the points raised, but the point which I had in mind, apart from constructional details, is that collet chucks, either of drawn-in or push type, entirely preclude any possibility of inaccuracy through wear such as might occur in Mr. McLaren's chuck. The predominance of collet chucks such as I refer to, in Canadian shops is one reason for my high opinion of shell makers in this country. Their rapid operation has had much to do with their popularity. One case in particular impressed me where 18 pdr. shrapnel had the bands machined complete from floor to floor in 27 seconds, this being due to the manner in which the chuck was automatically tightened by the movement of the carriage in bringing the tool into operation. In fact with a skilled worker the spindle was never completely at rest, a thing which could not happen with McLaren chucks. As a further argument in favor of the status of Canadian shell makers, I enclose sketch of expanding arbor for comparison with the one shown in catalogue. The Canadian article was built and in use three months after the war started. The two devices are similar but the English one lacks the adjustment obtained by the small handwheel, so that in case of large or small bore forgings the length of thread left in the tightening nut would be seriously diminished with consequent chances of stripping.



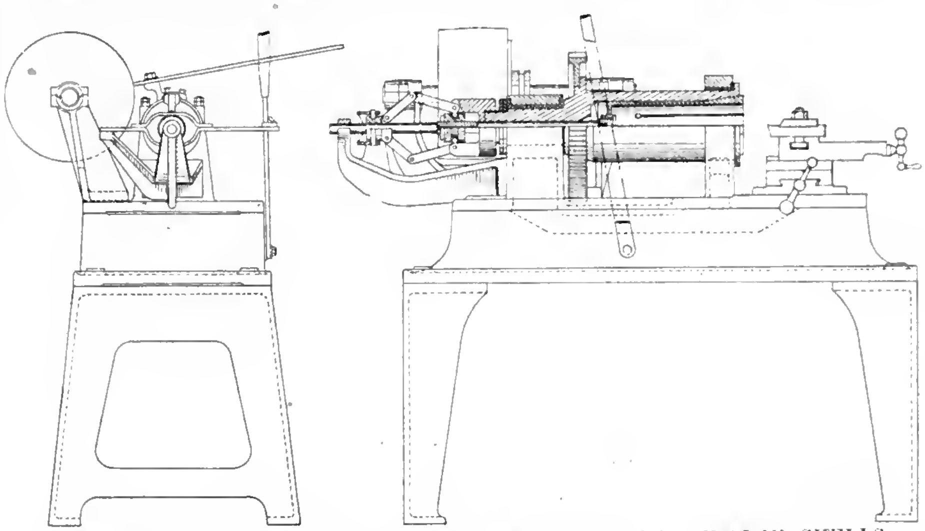
UPPER: CANADIAN ARBOR, AND LOWER, ENGLISH ARBOR REFERRED TO BY W. J. M.

In conclusion I might mention that I have seen 18 pdr. shrapnel rough turned, based faced and rounded in 4½ min., and bored complete inside to gauge in 39 sec., also 4.5 in. forgings are being cut off, base trimmed and rough turned simultaneously in an ordinary engine lathe with special tooling at the rate of 250 in ten hours, and not a single shell has been spoilt in the last machine out of 20,000, so far.

LATHE FOR SHELL BASE OPERATIONS

By H. P. Hoag

A SINGLE purpose lathe for facing off gas and plugs and adjusting weights of 4.5 Howitzer shells, and may be adapted to other base operations.



LATHE FOR FACING BASES AND SIMILAR OPERATIONS ON 4.5 IN. SHELLS.

The hollow spindle is of cast iron and the collett chuck can be of steel or brass. The lathe spindle is driven from a clutch pulley at the back through a pair of two to one gears, the belt pulley being 14 in. dia. by 6½ in. wide, running not less than 200 revs. per min.

The lever shown on front of the bed in both views opens the collet clutch when moved to the left, and also releases the driving clutch at the same time. After changing shells the collet clutch has to be tightened first, before the driving clutch can be engaged.

The lathe can be placed anywhere about the shop and belted direct to line shafts, no countershaft being used. With the above combinations of collet chuck and clutch pulley, controlled by short levers close at hand, this lathe is very quick to operate. It has all the advantages and none of the disadvantages of the air actuated outfits.

WELSH TIN-PLATE PRACTICE

THE London correspondent of the Iron Age writes as follows:—"A new tinplate plant has gone into operation in one of the Welsh works and has attracted considerable attention. The finished black plates as they come from the cold rolls and annealing furnaces are passed, without any handling, through the pickling, washing, tinning and cleaning processes, and the finished plates are piled up as completed, ready for boxing and shipment. One pot which has been running a few weeks under ordinary working conditions is turning out about 2,200 base boxes a week, and another pot, just started up, made even a better output. The innovation is said to be the most important since that of the morewood pot.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

VALVE RE-SEATING MACHINE

WHILE the Dexter Valve Re-seating Machine is not by any means a new appliance, recent developments and improvements in its construction have given it a wider range of usefulness in various branches of engineering, repair and overhauling.

When this device was first designed, it was then only contemplated to reseat globe type valves; other types of valves had not been considered. However; the success attained in their original purpose, encouraged the makers to further develop the apparatus, until at the present time the variety of uses to which it can be adapted is almost without limit.

Fig. 1 illustrates the latest improved type of machine for re-facing valves from 3 to 6 inches. It is shown operating on a flat-seated valve. The general construction of the various sizes is more or less identical, but, in the case of this and the larger sizes, special provision is made to reduce the power required to operate the cutter.

Where the small sizes are direct driven by means of the power handle secured to cutter spindle, the larger size machines, as shown in Fig. 1, are operated by bevel gears, running in special brackets; the gear ratio and bracket construction being, of course, suited to the size of the machine.

The jaws of the universal chucking arrangement can be adapted to either internal or external use, the long sleeve in which the cutter spindle revolves, insuring the utmost rigidity, even on the heaviest work. The faces of the cutters are so constructed, that all possibility of chatter is entirely eliminated, resulting in a clean smooth finish.

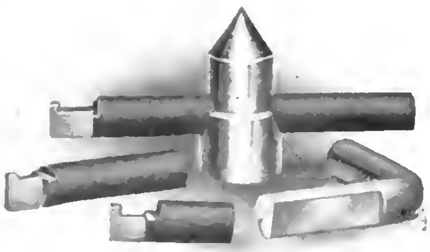


FIG 2 CUTTERS FOR CHANNELING WORN VALVE SEATS.

After a valve has been re-faced a number of times, there arises the possibility of cutting into the uneven portion of the metal surrounding the valve seat. To overcome this, and at the same time extend the life of the valve, the attachment shown in Fig. 2, has been designed. By this simple device, a channel is cut around the old seat leaving a new ridge for further facing. By removing the sleeve and cutter spindle from the universal chuck, and securing same in a special frame as shown in Fig. 3, the valve disc can be re-cut.

FIG. 1. MACHINE FOR RESEATING VALVES FROM 3 IN. TO 6 IN.

The adjustment and operation is quite simple. With one setting of the head, a crowning face can be cut, and, by feeding forward, on the knurled nut, a 45-degree angle can be cut. Again by utilizing the feed nut of the machine, a true surface can be turned parallel with the axis of the spindle.

While this device was originally designed for a special purpose, it may be adapted to many jobs ordinarily performed in a small lathe. A larger size, suitable for the heavier work is also constructed.

Darling Bros., Montreal, are the sole manufacturers in Canada of these machines.

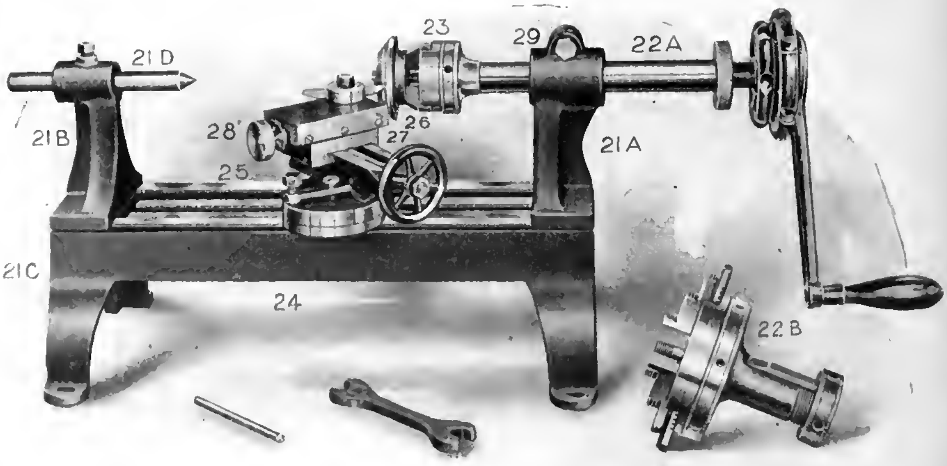

FIG. 3. RE-MACHINING DEVICE FOR WORN VALVES.

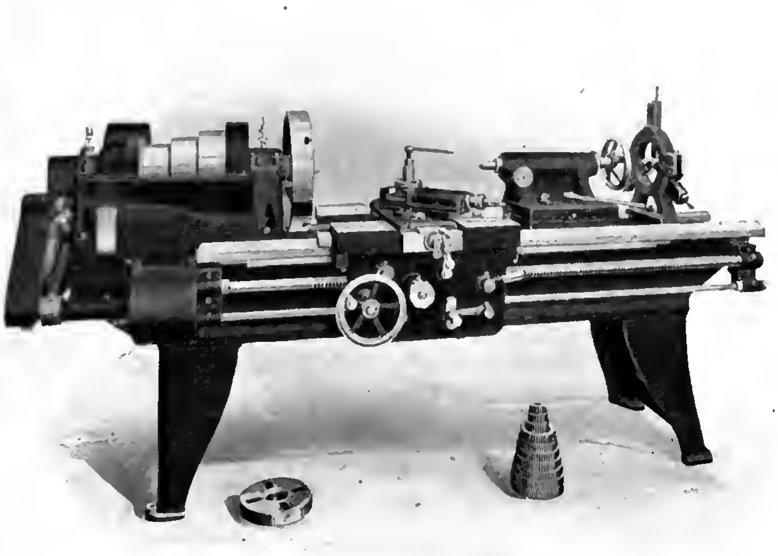
TOOL-ROOM GRINDER

A TOOL-ROOM grinder suitable for performing all grinding operations on fine tools has been placed on the market by the Dominion Machinery Co., Toronto. It is built in both plain and universal types, the former being supplied with headstock and tailstock, cutter support and double countershaft. The universal machine has additional equipment consisting of internal grinding attachment, swivel vise.

The table can be set to any angle for aligning centres and is graduated in $\frac{1}{8}$ of an inch per foot. Main spindle is hardened and ground and revolves in ring oiling bearings.

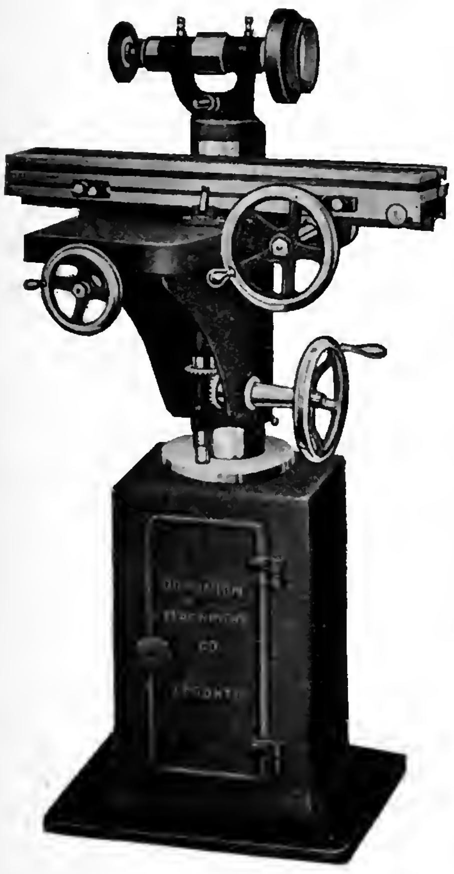
SEVENTEEN-INCH PLAIN CHANGE ENGINE LATHE

THE lathe shown in the illustration is built in two sizes, 17 in. and 19 in by the Sidney Tool Co., Sidney, Ohio. It is of the double back geared plain change type, possesses ample strength to perform heavy duty work, and is supplied with 8 ft. 10 ft. and 12 ft. lengths of bed.



17-IN. PLAIN CHANGE ENGINE LATHE.

Special attention has been given to the construction of the bed which is of 20 per cent. steel mixture, and is stiffened by double wall cross girts. Chilled vees are provided which confine the majority of the wear to the carriage, the vee for the carriage being $2\frac{1}{2}$ in. wide.



TOOL-ROOM GRINDER.

The compound rest is of rigid construction and has a circular swivel graduated in degrees. Full length taper gibs with end screw adjustment are fitted on both cross and compound rest slides.

An offset of 1 in. back of the centre line is given to the headstock so as to bring the pressure area more completely over the bed which is especially desirable in high speed heavy duty work.

The spindle is made of 50-point carbon steel, is provided with a 1 9-16 in. hole, and runs in phosphor bronze bearings, the front one being $5\frac{1}{2}$ in. dia., by $3\frac{1}{2}$ in. long, and the rear one $4\frac{1}{8}$ in. dia. $\times$ $2\frac{1}{2}$ in. long. A three-speed belt cone is used which with the back gear gives 6-spindle speeds ranging from 13 to 360 per min.

A one-piece apron is grooved, pinned and bolted to the carriage, and has a bearing for both ends of all gears. The lead screw is 40-point carbon steel, 1 7-16 in. dia. by 2 threads per in. A rigid type of tailstock is employed having short clamping bolts, and a double plug binder which maintains the alignment of the spindle when tightened.

The principal dimensions of the 17 in. lathe are as follows: Swing over shears 19 in.; swing over carriage, $11\frac{1}{4}$ in.; length betwen centres, 8 ft. bed, 48 in.; tailstock travel, 8 in.; and No. 4 Morse taper centres. The weight of these lathes is 3,500 and 3,700 lbs. respectively for the 17 in. and 19 in. sizes.

BUNDLING PRESSES FOR SCRAP METAL

THE prolonged activity in the engineering and metal industries brings with it many problems for the works engineer, not the least troublesome of which is the manipulation and disposal of the large quantity of scrap metal which so quickly accumulates. This scrap was bundled, but the old-fashioned way of hand bundling is totally inadequate to deal with the situation under the present conditions. Hydraulic power has now been found to be the most efficient and economical method of bundling the metal ready for re-melting or for handing over to the dealers.

Very successful bundling presses on the market are those made by Hollings and Guest, of Birmingham, England, who have specialized in this class of machinery. Three designs of presses are represented, one for bundling brass, copper, or aluminium; one for dealing with wrought-iron scrap and clippings; and another for briquetting swarf and borings. Since the outbreak of the war these machines have been installed by numerous munition works, metal rollers and scrap merchants, repeat orders having been received in several cases. There has also been a large demand for these presses from the French munition and ordnance works.

SLIP RING INDUCTION MOTOR

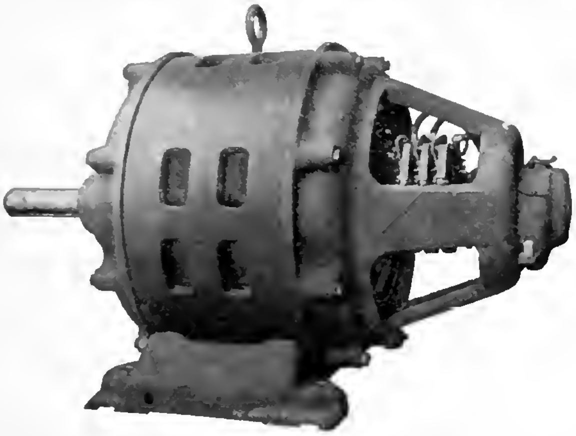
A NEW line of slip ring induction motors, (type CI) for severe, intermittent, varying speed service has just been developed by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa. These motors are especially designed for heavy duty on cranes, hoists, draw bridges, roller lift bridges, railway turntables, transfer tables and similar applications. They can be furnished in sizes from $1\frac{1}{2}$ to 200 horse-power for operation on two or three-phase, 220 or 440-volt, 25 and 60-cycle circuits.

10 HORSE-POWER MOTOR WITH BUILT-UP FRAME.

The frames of the smaller sizes are made up of steel laminations riveted between forged steel end shields; in the larger sizes the frames are made of rolled open-hearth steel. The brackets are of cast iron with reinforcing ribs to assure rigidity and perfect alignment of the bearings at all times. The bearings are self-oiling of the oil-ring type, and are large in size. The steel brush holders are supported by and insulated from

the bracket, which is open to permit easy inspection and renewal of these brushes.

The rotor is small in diameter, thus reducing the fly wheel effect. This feature, together with perfect balance and secure attachment of the windings,



75 HORSEPOWER MOTOR WITH ROLLED STEEL FRAME.

makes these motors especially adapted for frequent starting, stopping, and reversing. The shaft is of axle steel and can be removed from the rotor without disturbing the windings.

The running torque of these motors is the maximum obtainable and the starting and pull-out torques in all motors exceed twice full-load torque. They are so constructed, that in case of accident, repairs can be quickly made, and maximum strength is obtained while weight and overall dimensions have been reduced to a minimum.

The illustrations show a 75 horse-power motor, with rolled steel frame and a 10 horse-power motor with built-up frame construction.

MAMMOTH CONVEYOR BELT

CONFRONTING a sugar refining company some ten years ago was the problem of catching and carrying 125 pounds in a lump from a fall of 4 feet, at the rate of 3,200 per day. The solution of the problem was arrived at in the form of a 36-inch, seven-ply belt, which was installed at that time. Since its installation it is estimated that the belt has carried over 2,000,000,000 pounds of sugar before exhibiting any signs of wear. True, the belt is an enormous one and represents a large investment, but the service it has rendered is said to have exceeded all expectations. Recently, the same refinery installed a belt 1,443 feet long, 36 inches wide and weighing 11,983 pounds.

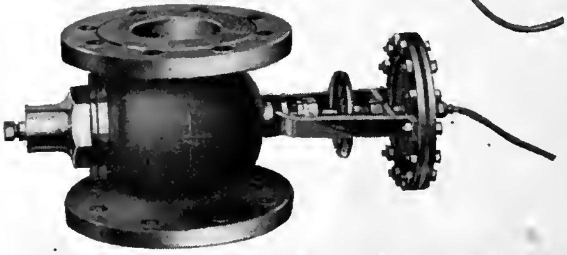
It is claimed that, estimating eight hours run without any delays, a bag of sugar will drop into the belt every nine seconds; and if the speed of the belt is such that it can make 26 to 27 revolutions every eight hours, the bags will rest at intervals of 12 feet apart. At this given speed, therefore, the belt will carry a continuous load of 60 bags or 7,500 pounds, and every nine seconds its heavily burdened surface will receive the sudden jolt and strain caused by 125 pounds dropping 4 feet.

CONTINUOUS FEED WATER REGULATOR

THE feed water regulator shown in the accompanying illustration is designed to regulate the supply of feed water to a boiler in exact proportion to the rate of evaporation, thus enabling the boiler to deliver a steady supply of steam according to the degree of heat maintained in the furnace.

No exhaust steam is discharged by this regulator which avoids the loss due to the use of live steam and its ultimate loss in the ash pit.

As a result of the absence of moving parts the S-C Feed Water Regulator is not subject to wear, and the absence of any necessity for replacement insures a long life for the apparatus.



VIEW OF REGULATOR ABOVE CONTROLLING VALVE ON FEED WATER PIPE

The S-C Regulator Co., Fostoria, O., state that because of its simplicity the device can be installed in about two hours.

FAST AND LOOSE PULLEYS

IN places where high speeds are used, if the loose pulley is simply faced square and bored out true in the way adopted in many works, there is a tendency to score and cut the shafting, and while this may not be dangerous on a good fibrous piece of metal, it is not too safe where metal is used which is liable to crystallize when fatigued is used. Outside any chance of danger, however, shafting which is scored is often awkward to deal with should alterations be needed, and if preventable the scoring should be avoided. To prevent trouble caused by the boring of the loose pulley itself, the edges of the boring should be rounded off and the cuts made should be finished smooth.

In a general fit up of a pair of pulleys, the keyway should not extend beyond the edge of the fast pulley next the loose one, as this last pulley should run on quite round shafting, especially where there is much dirt flying about. The collar should fit well and the set screw should not project above its surface, one of the many makes of safety collar or screw only being used. In fact, with all collars and similar projections from revolving machines there should be nothing to catch in the clothing of the persons employed on and around them. From time to time it is desirable that the collars shall be slacked and the loose pulleys run back and cleaned as well as the part of the shaft on which they run, as it not infrequently occurs that oil and dirt accumulates in the form of ridges, which are not beneficial to the working of any parts of machinery. Of course, some kinds of work are worse than others for free moving parts, but in all factories where much work is done, dirt and dust is unavoidably produced, and this is carried about by the air.

Varnishing Patterns. — A well-made pattern should be smooth, free from soft spots caused by the use of soft putty, and, above all, it should be impervious to moisture, or it will "suck" the mould and be hard to lift. To keep patterns in good order, they should be dressed with patternmakers' smooth shellac varnish as often as necessary, and in all cases it should be borne in mind that the smoother the pattern the smoother the casting produced from the mould. Where for any reason Plaster-of-Paris moulds are used, these should be dried and warmed, and then have their surface soaked with melted paraffin wax, to prevent absorption of moisture. Plaster patterns treated in this way brush up with a smooth surface, and for many purposes they answer as well as wood, while costing, in comparison, a mere trifle.

A BOOST FOR CANADIAN SHIPBUILDING

THE North Sea battle, among other things, should give a decided impetus to the encouragement and development of shipbuilding in Canada. An appreciable dent has been made in our naval fighting machine, more so than any of us were prepared for, and while the ultimate ability of the latter to maintain its superiority is well beyond question, we may not be insensible to the fact that any immediately projected mercantile shipbuilding programme in Great Britain has received a substantial setback for some time to come.

It would be well for our Canadian business and public men to ponder over not only the recent happening, but to become awake to the fact that it is not by any means the last of its kind. There is a meantime serious shortage of merchant shipping the world over, and, while the war lasts, the shortage volume in the nature of things cannot but increase. However much we may desire it otherwise, there must also ensue a diminution of our naval fighting strength from time to time, and to readjust same it is readily apparent that Government control of British shipyards will continue effective.

As hinted in Sir Robert Borden's speech at the launch, the ice-breaker "J. D. Hazen" is to be pressed into service on behalf of the Allies. She, in a word, is to be diverted from her original purpose, and, in so determining, our action is altogether praiseworthy; but why stop there? In the case of the ice-breaker disposal we have undoubtedly made a sacrifice, for we had looked forward to her work on the St. Lawrence as influencing our trade and commerce to a material extent. On the other hand, the development and encouragement of shipbuilding on our ocean waterways and ocean shores would essentially be void of sacrifice, while the resultant product would be equally and perhaps more valuable to our Allies, and at the same time of untold benefit to ourselves, industrially and commercially.

We are disposed from a study of the facts and otherwise, available, to credit our North Sea enterprise as a display of reckless daring. The sacrifice in men and machines may, however, have been warranted; in any case only one fleet kept to sea, and that was Britain's. The responsible Government of Canada in this time of stress is well and far removed from any imputation of daring — without the reckless qualification, so much so that no little popular satisfaction would be felt were the lifeless inactivity replaced by even the slightest evidence of awakening interest in a Canadian shipbuilding programme.

The prophecy that with the lapse of some fifteen or twenty years hence, shipbuilding costs as between Great Britain and Canada will be equalized, smacks of the "Live horse and you'll get oats" wheeze, on which account alone it is absurd, while in the light of present-day conditions it indicates a rank ignorance of men and things. The cost of merchant shipbuilding in Great Britain is now higher by far per ton than it ever has been in Canada, and irrespective of the contrast between the two countries in pre-war days, it has to be borne in mind that in the new order of things, existent, and sure to prevail in post-war days, it is odds on a bet whether the cost difference will be other than negligible.

Being misinformed or uninformed is no excuse for the neglect of Canada's public business by her public men, the opportunities from within and from without to be otherwise, being readily available.

REVISING LARGE SHELL SPECIFICATIONS

CONSIDERABLE interest has been aroused in manufacturing circles by the announcement of impending changes in large shell specifications, and until a final decision is made, it will not be possible to arrive at an accurate estimate as to the effect of such changes on the rate of output or on the cost of the shells.

It would seem not unlikely that such changes as may be made will be for the purpose of lowering production costs, increasing output, or bringing about some desirable improvement in the construction of the shell as dictated by extended use in action.

Published accounts of large shell-making in Britain which have appeared in this and other engineering journals, have shown shell forgings of parallel diameter, necessitating a subsequent nosing or bottling operation. Up till now, forgings produced in this country have been made with a closed nose, the curve being formed by the die in which the billet is pierced and forged to size, it being possible to do this work in a single operation. Suitable machines and tooling outfits have enabled these curved surfaces to be finished with a high degree of accuracy and expedition, access to the interior being had through the open base.

The use of forgings of the open mouth closed base type as foreshadowed by present advices, while involving the discarding of some tooling outfits, should not necessitate sufficient change in machines to cause any apprehension amongst makers of larger shells. It is more than likely that improvements in nosing or bottling equipment will enable the curve of the shell to be formed with sufficient accuracy to dispense with a subsequent final cut on the inside.

While a decision regarding a closed base is still pending, the arguments in its favor seem to justify its adoption, the saving in expense and labor over the open base being more than sufficient to offset the expense of tool replacement, although the feature of additional safety under firing conditions may ultimately be the decisive factor in the problem.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, June 5, 1916.—Industrial activity throughout all branches of metal trades continues. Many firms are experiencing considerable difficulty in securing and retaining suitable help for the operation of their factories. This in many instances has resulted in increased wages, which, added to the higher cost of raw materials and needed supplies, has materially affected the economic aspect of all lines of production. Additional orders for 6, 8 and 9.2-in. shells are continually being placed, and the necessary machinery for their production is being acquired as rapidly as possible. Domestic conditions are improving: but the excessive cost of material has much to do with the deferred activity in many lines of normal industries.

Steel

The general situation throughout the steel industry shows little change, and with mills and furnaces working to capacity on present and future orders, the market is inclined to remain stationary. Owing probably to lower ocean freight rates, the foreign demand for steel is constantly increasing. The domestic interests are suffering to a large extent, as they do not feel willing to place orders at the present high prices. Billets and sheet bars are firm, with deliveries improving. The demand for plates has been so heavy that many of the large mills are booked well into 1917. This condition also prevails in the sheet mills, and blue annealed and special sheets are in good demand. Galvanized sheets are in fair demand, but owing to the decline in spelter are inclined to weaken. Some of the mills are using all available steel in material that will return them the best profits. Railroad spikes are fairly active, and the same may be said of all bolts and nuts. Consumers of rivets are well covered, and present market is quiet. Following the recent activity in wire goods, the trade has become quieter; general conditions are unchanged, with prices firm in all lines.

Metals

The general market is in a rather turbulent state owing to the action of the British authorities in placing certain restrictions upon the purchase of copper and other metals. This may be followed by a readjustment of prevailing prices. Copper is quiet and easier. Tin is inclined to be dull and continues to decline. Spelter has experienced a sharp break in London, and is unsettled here. Lead is quiet, and has a tendency to become weaker. Unexpected supply of antimony has been the cause of recent weakness.

Copper.—The copper market is exceptionally quiet, and prices are inclined to be easier. Consumers are apparently well covered for early future requirements, and little interest is being shown even at shaded prices. Offerings of resale metal have resulted in a slightly weaker market, but with the exception of castings, the quotations are unchanged. Owing to the recent action of the British Government, dealings of a speculative nature are now prohibited. Hereafter all purchases made must be for metal to be used in the buyer's plant. This ruling also applies to copper imported from the States, and agencies can only buy and sell metal on consumers' orders. This feature of the London market may be followed by a readjustment of copper prices as well as other metals. Present quotations in London show a decline of £1 and £2 on spot and future standard, and £8 on electro copper, prices quoted being £120, £118 and £140 respectively. With the exception of castings, New York prices are unchanged, and are nominal at 28½c for lake, 28¾c for electrolytic, and 26⅛c for castings, the latter being a decline of ½c per pound. Foreign conditions have not yet affected the local situation, and dealers here report a firm but quiet market, with prices unchanged at 32c for lake and electrolytic, and 31c for castings.

Tin.—The market is very quiet: so much so, that even with marked declines very little business is being transacted: and the bulk of this only on substantial concessions by the sellers. Developments in England are causing considerable un-

easiness among certain dealers in metals, and further restrictions on trading may seriously effect these interests. The evident result of this recent action is reflected in the sharp declines on London quotations, which show a reduction on the week of over £7. Standard tin is now quoted at £185 15s. for spot and futures, and £186¼ for Straits tin. New York continues to weaken, and sufficient buying has not developed to arrest the decline. Should the market show any signs of steadying, it is thought by the trade that additional buying would develop, as future purchases have been very light for some time. On a decline of 2⅛ cents, New York is quoting 45¼ cents nominal. Dealers here report a quiet and unsettled market, with prices weaker; 48 cents is being quoted, a decline on the week of 1 cent.

Spelter.—The situation in spelter is very unsettled at the present time, owing to another sharp break in London market. No reason is given for the recent decline, and an interesting feature in connection with the present situation is the fact that present prices in London are now below those in New York, which for many weeks have been much the other way. Consumers' inquiries are fairly good, but in face of the latest developments it is doubtful if much business will be closed until the present situation becomes clearer. A decline of £20 on spot and £15 on futures puts present quotations on the basis of £70 and £60 respectively on the London market.

Until further information is available, the New York market will hold firm on their current quotations. Present prices of 13 cents shows a decline of 1 cent on the week. The local situation is slightly easier, but quiet; dealers report a decline of ½ cent, and are quoting 19 cents per pound.

Lead.—The market is dull and, in the face of light inquiry, prices are inclined to become easier. Domestic requirements are also light, and the trade is expecting to see a decline in early future quotations. Outside interests are a little below the Trust prices, and as the supply appears to be fully equal to the demand, it is more than likely that lower prices will prevail in the near future. London reports a fair market with slightly stronger prices, but conditions here tend to become easier. The local situation is unchanged, and prices are firm at 9¼ cents per pound.

Antimony.—The situation continues to weaken and further declines are reported. The cause of the recent falling off in the price of antimony is largely owing to the cancellation of considerable Russian business, which has resulted in large quantities of Japanese metal being placed on the market. The effect of this unlooked-for supply has been shown in the recent break. However, it is reported that this metal is now being withheld from the market, and a steadier tone may be expected. A decline of 2 cents is noted in the New York prices, which are quoted at 25 cents. Local dealers are quoting 36 cents, being a decline on the week of 2 cents per pound.

Aluminum.—Conditions are comparatively unchanged, with prices steady at 68 cents per pound.

Machine Tools and Supplies

Conditions throughout the machine tool industry continue to maintain a fair degree of activity, but the demand for shell making equipment (especially of the smaller sizes) is now confined to individual machines. The requirements for the heavier shells, however, continue to keep the machine tool builders busy, and a considerable volume of business in this direction is everywhere evident. Delivery on machines is improving, and delays, owing to non-shipment, are becoming less frequent. The small tool and supplies demand is easing up a bit, and a feeling of relief is prevalent in many lines.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Old Materials

The trade in scrap metals, while still of considerable volume, is nevertheless quieter than for some time, and prices are becoming weaker. Quotations, however, are still nominal at last week's figures, with the exception of zinc scrap, which is quoted at 12 cents, a decline of ½ cent.

Toronto, Ont., June 6.—Trade conditions continue favorable as regards the volume of business moving but the shortage of raw materials and labour are causing considerable anxiety to manufacturers. This is true particularly in the case of iron and steel, as the mills are getting more backward on deliveries owing to the heavy demand. Reports from London, England, indicate that the Export Association of Canada is doing some very effective work and their connection is being considerably extended. The Customs returns continue to show increases. The Dominion revenue for the month of May totalled $13,054,381, and represented an increase of $5,738,457 over the corresponding month of last year. The revenue for the port of Toronto for May amounted to $3,092,538, being an increase of $1,607,294 over the corresponding month of last year, thus establishing a record for the total revenue.

The steel market is steadier and quotations are very firm although the upward tendency is less pronounced than it was. The mills continue to operate at capacity with sufficient business on hand to carry them well over into 1917. The weakness in the ingot metal markets continues and prices on a number of metals have declined. Copper, however, although dull is unchanged, and prices are holding firm. There is nothing in the scrap metal market to call for any particular comment. The market is weaker and some metals have declined.

Steel Market

The upward movement in prices is less pronounced, the market being much steadier and still very firm. The general situation, however, is unchanged and the present high level of prices will, no doubt, obtain for some considerable time. The demand on the mills for material is as insistent as ever and there is no sign of any falling-off in demand. There is, therefore, little possibility of any weakness developing in the market with a continuance of present conditions. Deliveries are as backward as ever and are a serious handicap to many makers of finished products; the result being continued high prices and a shortage of many lines. The most important advance this week is in seamless boiler tubes, prices being about 5 per cent. higher for most sizes. The mills are practically sold out for the remainder of the year on both iron and steel locomotive and merchant tubes. The market is very strong and a further advance is expected in the near future. Prices on wrought iron pipe are very firm and an advance is highly probable at no distant date on account of the shortage of skelp. It is reported that many skelp mills have their output sold up for practically the remainder of the year. Boiler plates are also very firm and deliveries backward, some plate mills are sold up for the remainder of the year.

The sheet market is very firm; prices on black sheets have an upward tendency, although galvanized are easier. Light black sheets continue to be readily obtained while heavy gauge as well as blue annealed are as scarce as ever. The continued decline in spelter has had its effect on galvanized sheets, but the price of this metal is still too high and the market too unsettled to materially benefit the galvanizers.

The high level of prices in the United States is being well maintained and the

steel market is very firm. New orders are not in such large volume but there is no sign of weakness in the market. The outlook in the steel trade continues very bright and the mills are booking orders into the second quarter of 1917. Steel bars are unchanged at 3c, plates 3.75c, and shapes 2.60c, Pittsburgh.

Old Materials

The market for scrap metals has a weak tendency and prices of some materials have declined. The domestic demand is light but the manufacture of munitions is still absorbing considerable quantities of some metals. Lower prices have to be noted for copper ,brass, heavy melting steel, lead and zinc.

Machine Tools

The orders for heavy duty lathes reported in these columns last week as pending, have been held up temporarily. Changes in the method of making the 8 in. and 9.2 in. high explosive shells are under consideration involving a considerable difference both as regards forging and machining from the practice which is being followed at present. When the question is settled it is expected that there will be some nice orders placed for large-swing lathes. Deliveries on single purpose lathes are good, but, on standard tools, slow. A better demand for woodworking machinery is reported but the ordinary business is comparatively quiet.

Supplies

Business continues good and the market steady but firm. The upward movement in prices is slowing down, indicating that the prices on finished products are more or less adjusted in line with the cost of raw materials. The price changes this week include "Trimo" and "Stillson" wrenches which are now quoted at a discount of 55 per cent. as against 60 per cent. formerly. Wood pulleys now carry a discount of 50 per cent. Linseed oil has declined again and is quoted at 80c for raw, and 83c for boiled oil, per gallon.

Metal Markets

The decline in prices of metals continues, copper being the only one not affected. The lower prices are due to a general decline in London, where the market has been affected by peace rumors. As the possibility of an early peace is remote, the market should recover and a re-action set in. The copper market is steady due to the recent order of the British Government, now in effect, prohibiting speculation in copper. The tin market is dull and stagnant, and prices have declined. Spelter is also lower and the market disturbed, following sharp decline in London. The "Trust" price for lead is unchanged but the outside market is lower. Antimony and aluminum are weaker and prices have declined. Solders are unchanged.

Copper.—The market although dull has not followed the weakness in London, quotations and prices being unchanged. Consumers generally are displaying but little interest, and producers are not pressing copper on the market. The undertone is very strong with the view is generally held that it is simply a question of awaiting the next buying movement. Quotations are unchanged and nominal at 31½c per pound.

Tin. — The market is quieter with quotations slightly lower. Consumers are still holding off but some good buying is expected as soon as the market shows signs of steadiness. The position of tin is a good one and it is selling at a low basis compared with other metals. Tin has declined 1c and quotations are nominal at 51c per pound.

Spelter.—Quotations continue to decline and the market is unsettled following a sharp break in London. It is probable that a re-action will set in and prices advance. Local quotations are lower at 19c per pound.

Lead.—The market is dull and lower on the outside market but the "Trust" price of 7.50c New York is maintained. The demand continues light and buying at present is of a hand-to-mouth order. Local quotations are a shade lower at 9¼c per pound.

Antimony.—The market is unsettled and lower due to an increase in available supplies. Quotations are nominal at 38c per pound.

Aluminum.—The situation generally is unchanged but the market is weaker and quotations have declined to 64c per pound.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

RUSSIAN TRADE WITH UNITED STATES

H. BUNNELL, has resigned from the Griscom-Russell Co., with whom he has been in an engineering and sales capacity for the past nine years, and has become chief engineer of R. Martens & Co., Inc., the New York connection of R. Martens & Co., of London, of which David A. Thomas (Lord Rhondda) is president, and Richard Martens, a Russian by birth and citizenship, is vice-president and general manager. The firm has it own pier on Staten Island, and will operate a line of steamships to Russian points after the close of the war.

In preparation for the extensive business which will be done between Russia and the United States, the Russian branches are investigating the conditions in the engineering and agricultural fields through a force of English and American engineers who will spend the next six months in Russia. The New York house will carry on the work of arranging to represent American manufacturers in Russia and of transmitting information, prices and descriptive matter through the Russian office. Catalogue descriptions of various American lines are being put into Russian, and at Petrograd an extensive loose leaf catalogue will be issued. The Russian branch houses are at Petrograd, Vladivostok, Moscow, Archangel and other branches will be established at Odessa, Tomsk and Baku.

"SOO" CANAL TRAFFIC

THE statistical report for May of traffic through the canals at Sault Ste. Marie, Michigan and the Sault, Ontario, shows the heaviest traffic for one month yet received; 10,164,562 tons passed through the American Canal, and 2,128,-914 through the Canadian.

Iron ore, grain and wheat continue to head the shipping list, showing a tremendous increase over May of last year of the former. May, 1915, showed a 4,-906,788 tons, as compared with 8,144,555 tons in 1916; grain, 5,497,071 in 1915, against 15,837,114 in 1916; wheat, 13,-267,497 in 1915, against 37,333,403 in 1916.

Soft coal also shows an increase—1,248,447 tons in May of last year, and 2,075,552 this year: 1,756 passengers passed through on steamers, an increase of 412 over May last year; 3,215 vessels were locked through, 776 of them through the Canadian Canal. The tonnage locked through the canal for the past month was more than the total amount handled in a season through the canals 24 years ago. Of iron ore, nearly

twice as much was handled last month as in that year, and 82,646 tons more than in the entire year of 1895. As many lockings were made during May as in 1894.

RUSSIAN ENQUIRY FOR LOCOMOTIVES

THE Russian Ministry of the Interior has sent out an enquiry for from 600 to 1,000 large locomotives. The exact number to be purchased is not stated, but it is expected that a portion of the order will be divided between the American Locomotive Co. and the Baldwin Locomotive Works. Last year an inquiry from the same source for from 400 to 600 locomotives resulted in the placing of orders for 350 engines in the United States, and 50 in Canada. In consequence it is thought that about 500 engines will be placed with American concerns, and 100 in Canada, for the current inquiry.

The engines are to be of the same type as those ordered last year, and will cost somewhere between $27,000 and $30,000 each probably nearer the higher figure. The money total of the order, if 500 locomotives are purchased, will be about $15,000,000. One advantage lies in the fact that the type is unchanged so that it will not be necessary to make new patterns, usually an important item of expense.

ITALY'S METALLURGICAL FUEL REQUIREMENTS

OWING to the coal shortage in Italy, due to reduced imports, the Associazione degli Industriali Metallurgicai Italiani has emphasized the necessity of a regular supply to metallurgical and engineering works so that the interests of natural defence may be safeguarded. Three grades of coal are particularly mentioned: Steam coal, such as Cardiff and others; gas-producer coal for open-hearth furnaces, chiefly Scotch coal, splint, etc., and reheating furnace fuel, usually the splint class or New Pelton. The normal annual fuel requirements of the chief works are as follows: Blast furnaces, 800,000 tons of coke; open-hearth furnaces, 300,000 tons of coal; reheating furnaces, 40,000 tons of coal; boiler furnaces, 510,000 tons of coal; foundry cupolas, 50,000 tons of coke; foundry boilers, 50,000 tons of coke; works producing wire and other finished steel, 100,000 tons; brass, copper and lead foundries and smelting works, 30,000 tons of coal, and 50,000 tons of coke; machine shops, 100,000 tons of coal.

CUSTOMS REVENUES

THE Customs revenue of Canada for the first two months, April and May, of the fiscal year show an increase of nearly ten millions of dollars. The revenue for the month of May accounted for the larger proportion of this increase, the Customs collections reaching a total of $13,054,381, as compared with $7,315,923 for the corresponding month in the previous fiscal year, an increase of $5,738,457.74.

The returns are regarded as highly satisfactory as the figures include drawbacks on re-exported munitions and similar commodities.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Montreal, Que.—The British American Oil Co. will make an extension to their plant at Outremont.

Guelph, Ont.—F. Callandar will shortly begin the construction of a foundry here to cost about $7,000.

Quebec Bridge Progress.—The middle span of the Quebec Bridge will be in place this summer, or in the early fall, completing the shore-to-shore steel of the world's greatest bridge.

Calgary, Alta.—The Threshing Machine and Tractor Co. announces that it will start the erection of a new plant here in August. Plans are now being prepared.

Ontario Mining Room.—The value of the production of metalliferous mines and works in Ontario in the first three months of 1916 is $14,276,382, as compared with $9,358,210 for the corresponding period last year.

Tillsonburg, Ont.—The Tillsonburg Metal Stamping Co., which was established here some months ago by J. C. Inman, has been taken over by the Chatham Malleable Steel Co.

General Industrial

tor at Kelsey has been destroyed by fire.

Lindsay, Ont.—Horn Bros. will proceed with the construction of a woolen mill. The cost will be about $25,000.

Montreal, Que.—The Marcus Loewe Co. will build a large theatre here. The Fleischman Construction Co. are the general contractors.

Regina, Sask.—The Canadian Consolidated Rubber Co., will build a warehouse here to cost about $24,000.

Wallaceburgh, Ont. — Several thousand dollars damage was done at the Dominion Glass Co. plant recently by the bursting of a furnace containing molten glass.

Sarnia, Ont.—A stone-cutting plant is likely to be erected in Point Edward, with a capitalization of $100,000. The stone from Indiana for the new Union Station at Toronto will be worked up at this plant. George Oakley & Son, of

Calgary, Alta.—The North Star eleva-

Markham, Ont.—A new company, composed of prominent business men of this district, intends to build one of the largest and most modern mills in York County. It will be situated at Markham Station, and the cost is estimated at $60,000. The chief stockholders are A. W. Milne, proprietor of Milne's mill, D. E. Jones, and J. Schurr.

Medicine Hat, Alta.—The Lake of the Woods Milling Co. has let the contract for the building of a mill to replace that recently burned down. The new plant will cost approximately $200,000, and will have a capacity of from 1,500 to 2,000 barrels. In addition, the company will erect a number of elevators in the West this year.

Municipal

Warwick, Ont.—A proposal is under consideration to instal a Hydro-Electric system in Warwick Township.

Preston, Ont.—The town council will shortly submit a by-law to authorize the expenditure of $10,000 on a fire engine.

Almonte, Ont.—The Town Council is considering the question of adopting Hydro-Electric power. An up-to-date system would cost about $18,000.

Markham, Ont.—The waterworks here are being enlarged so that the village may supply Mount Joy and Vinegar Hill. The contract has been awarded to a Toronto contractor, and mains to the two villages are now being laid. In one case it will be necessary to lay over two miles of main.

Sarnia, Ont.—The city has taken over the power plant and lines of the local electric company, and will operate it until Niagara power arrives in a couple of months. The plant costs Sarnia $180,000, and will be changed from a 60-cycle to 25 as soon as the Hydro arrives. The Hydro transmission line is now nearing Sarnia.

Hull, Que.—A by-law authorizing the purchase of a combination motor pump, hose and chemical motor truck; also about 1,500 feet of hose, and to extend the water works to Tetreaultville was passed by a large majority. The by-law calls for the expending of about $140,000, of which from $13,000 to $15,000 will be allocated to the purchase of motor apparatus.

Tenders

Ottawa, Ont.—Tenders will be received up to June 17, 1916, for the construction and erection of viaduct, station and train shed at Levis, P.Q. Plans, specifications and blank form of contract may be seen at the office of the chief engineer, Department of Railways and Canals, Ottawa, Ont.; at the office of the chief engineer, Moncton, New Brunswick; at the office of the resident engineer, Levis, P.Q., and at the office of Ross & McDonald, architects, Montreal, P.Q.

The Pas, Man.—Tenders, addressed to H. H. Elliott, M.D., secretary-treasurer of the Town of The Pas., Man., will be received up to June 22, 1916, for the supply and delivery of the following machinery and materials:—Tender "A"—For the supply and delivery of two sewage lift pumps. Tender "B"—For the construction of a sewage lift chamber. Plans and specifications may be seen at the office of Murphy & Underwood, consulting engineers, Saskatoon, Sask., and the resident engineer, The Pas, Man.

London, Ont.—Tenders for the erection of the new Technical and Art School on Dundas Street will be received till June 12, at the office of the secretary of the Board of Education. Plans and specification may be seen at the offices of the architects, A. E. Nutter, Dominion Bank Chambers, and Watt & Blackwell, Bank of Toronto Chambers. Plans for heating and ventilating and wiring may be seen at the offices of the above architects, or at the office of H. P. Elliott, heating engineers.

Railways—Bridges

The American Lead Pencil Co., New York, have prepared sample boxes of their "Venus" pencil, with pocket testing holder.

Savage Mills, Que.—A request has been made to the Provincial Government for a subsidy towards the construction of a permanent concrete bridge over the Yamaska River, at this place.

Winnipeg, Man. — J. D. McArthur, railway contractor has received a loan of $2,000,000 in connection with the construction of the Edmonton, Dunvegan and British Columbia Railway.

Vancouver, B.C.—Plans for the Canadian Northern passenger terminals on

About that Motor—

?

For the convenience of our customers we have anticipated to some extent the demand for Electric Motor Equipment and carry at Toronto a large stock of 3 phase, 25 cycle, 550 volt motors.

The A. R. Williams Machinery Co., Ltd.

64-66 Front Street West - Toronto If It's Machinery - Write Williams

Thousands of Threaded Pieces Each Day with a Geometric Threading Machine

RAPID AND PERFECT DUPLICATION

Takes floor space 2 ft. x 3 ft., and is complete with countershaft, change speed gear for adapting speed of spindle to diameter to be threaded; adjustable stop for gauging length of work.

No rough threads with the Geometric. They are as true and clean as can be produced by any screw machine.

Note the range:—Regularly, ¼-in. to ¾-in. Specially, ½-in. Std. pipe threads; ⅞-in. S.A.E. Std. Spark Plug threads, and up to 2-in. Diam. threads where the pitch is fine. Internal threads, ⅛-in. to 2-in.

Send in your Specifications and learn what we can do for you.

THE GEOMETRIC TOOL COMPANY
NEW HAVEN, CONN., U.S.A.

Canadian Agents: Williams & Wilson, Ltd., Montreal; The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg and St. John. N. B.

False Creek will be completed this week and Vancouver contractors will be given an opportunity to figure on them early next month.

St. Thomas, Ont.—Work is progressing rapidly on the T., H. & B. railway line from Dunnville to Port Maitland, which is preparatory to the inaugurating of a car ferry across Lake Erie. The line, which is about five miles in length, was started about one month ago. The plans also included the building of a slipdock at Port Maitland.

Trade Gossip

The Automatic Paper Box Co., has increased its capital stock to $200,000.

St. John, N.B. — Development work has begun upon the tungsten mines near Burnt Hill, Northumberland County.

Mussens, Ltd., Montreal, have been awarded a contract for two gasoline-driven diaphragm pumps by the Board of Control, Toronto.

The Smart-Turner Co., Hamilton, Ont., have been awarded a contract for a high power duplex pump by the city of Toronto for the high level pumping station.

Prices Wanted.—A reader of Canadian Machinery is desirous of getting information as to where prices can be obtained on rawhide packing suitable for hydraulic pumps. Will someone oblige?

Victoria, B.C.—The Victoria & Island Development Association, the Manufacturers' Association, the Retail Merchants' Association and other kindred organizations propose to amalgamate with the Board of Trade in order to develop and encourage new industries.

St. John, N.B.—The Federal Government has decided to erect a million bushel grain elevator here in connection with the Canadian Government Railways system. It is expected that the first unit of 500,000 bushels will be ready for use the coming winter season.

Error in Advertisement.—Through a typographical error, part of the text of the Mackinnon, Holmes Co., advertisement on page 6 of our May 25 issue implied that "hydraulic press equipment for forging shell plugs was a product of that firm." It should have read that "their plant was equipped for forging shell plugs."

Victoria, B.C. It is said to be the intention of the Provincial Government to bring in a bill shortly making a special grant of $40,000 for the purchase of new machinery for the treatment of zinc ores at the experimental plant at Nelson. Some time ago the sum of $20,000 was expended on apparatus at Nelson for the treatment of ores providing for the removal and saving of zinc. Ores carrying zinc are penalized at refineries and any preliminary process which will remove the zinc without losing it will admittedly be of considerable value.

Ottawa, Ont.—The Public Works Department has under consideration the matter of the approval of plans for the construction of a canal between Lake St. Francis and Lake St. Louis by the Beauharnois Light, Heat & Power Co. The proposed scheme involves a considerable development and, in all probability, will eventually result in the closing of the Soulanges Canal, in which case navigation would be diverted to the new canal between Lake St. Francis and Lake St. Louis. The Soulanges Canal is only ten or twelve feet deep, while the proposed Beauharnois Canal would be twenty-two feet.

Ottawa, Ont.—The Dominion Government has appointed the firms of Marwick, Mitchell, Peat & Co., and Price Waterhouse & Co., as auditors of the C. N. R. and the G. T. P. R. systems respectively. The duties of these firms will be to make on behalf of the Government a continuous audit of the revenues and expenditures of the railway systems in question and report to the Government the result of such audit from time to time. The appointments have been made in pursuance of statements made in the House by the Finance Minister in connection with the legislation authorizing loans to these two railway companies.

Government Stands by Hydro Scheme.—The material setting forth the position of the Province of Ontario in regard to the diversion of water at Chippewa Creek for the proposed new hydro development has been sent by Hon. I. B. Lucas to Ottawa, where it will form the basis of the Dominion Government's reply to the objections raised by the United States Government recently. The Ontario Government has taken the stand that it is within its rights in diverting water from Chippewa Creek, but a detailed statement of the Government's answer will be left to the Federal authorities, in whose hands such international matters properly rest.

Trade After the War.—E. R. Stettinius, head of the export department of J. P. Morgan & Co., on his return to New York, after an absence of two months in Europe, is reported to have stated that most of the reconstruction of the European countries now at war will be done by themselves when the war is ended. Many of the large factories which have sprung up for the production of war munitions will be utilised for other purposes when the war is over; many of the men returning from the front will have to be given employment, and he did not anticipate any great influx of business to the United States in what he termed the work of reconstruction.

Personal

Chatham, Ont.—The Board of Trade are negotiating with a company who are looking for a site to establish a factory and may locate here.

James Carlton Eckliff, president of the Eckliff Automatic Boiler Circulator Co., died at his home, 30 Melbourne Ave., Detroit, Mich., on May 9.

H. A. Breckenridge, formerly with the Montreal Locomotive Works, Montreal, has become purchasing agent of the Lima Locomotive Corporation, Lima, Ohio.

Heineman Johnston, of Ottawa, the new Trade Commissioner to Bristol, England, who replaces E. D. Arnaud, who died recently, has entered upon his duties.

L. D. Wilgress, Canadian Trade Commissioner to Omsk, Siberia, has left for Petrograd. Mr. Wilgress will look after the development of Canadian trade in Siberia.

C. Lamont has left Weyburn, Sask., for Collingwood, Ont., where he has received an appointment as chemist in the munitions department of the Kennedy Steel Works.

John G. D. Cook, a draughtsman at the Kerr & Goodwin Works, Brantford, Ont., leaves shortly for Siberia, where he will represent a mercantile firm, reporting to it on business conditions.

Arthur Drummond, son of the late Sir George Drummond, of Montreal, died on May 29 at the Royal Victoria Hospital. The deceased, who was in his 48th year, was general manager of the Canada Sugar Refining Co., Montreal.

Harry C. Slemin, formerly advertising manager, Yawman & Erbe Mfg. Co., Rochester, New York, has been elected managing director of the Office Specialty Mfg. Co., Newmarket, Ont., to succeed J. F. Wildman, resigned. Mr. Slemin was born in Toronto in 1879.

Captain John Simpson, veteran Canadian navigator and shipbuilder, died on June 3 at this home, Owen Sound, Ont., in his ninety-first year. He was born in the Bay of Quinte district near Belleville. When twelve years of age he began his career as a sailor and visited many parts of the globe before the mast

on clipper ships. After he became captain he was master of sailing ships on the Great Lakes and had all the experiences which come to the navigators before steam supplanted canvas. During the winters he learned shipbuilding with his uncle, a notable shipbuilder of Oakville, Dennis Potter, and it was in the ships he built rather than the ships he sailed that he will fill a position in Canadian navigation affairs. He came to Owen Sound in the fall of 1874 to build the steamer City of Owen Sound for A. M. Smith & Co., who had purchased the burned hull and machinery of the City of London.

Contracts Awarded

Toronto, Ont.—The Canadian Bridge Co., of Walkerville, Ont., have been awarded a contract for 5,000 tons of structural steel for the new Union station here.

Regina, Sask.—The Canadian Consolidated Rubber Co. has awarded a contract for a warehouse, to cost about $30,000, to the Poole Construction Co., Regina. Alex. Melville is the architect.

Medicine Hat, Alta.—The contract for the erection of a flour mill for the Lake of the Woods Milling Co. has been awarded to Carter-Halls-Aldinger & Co., Winnipeg. Approximate cost $200,000.

St. John, N.B.—The City Council has awarded a contract to James Fleming for 20 tons of special castings, and a number of sewer manhole covers, vault covers, fireplug platform covers, catchbasin frames and basins.

Toronto, Ont.—The City Council have awarded the following contracts for parts necessary for the construction of civic cars as follows:—Bodies, Preston Car & Coach Co., Preston, Ont., price, each, $4,907; trucks, Dawson & Co., per set, $828.50; electrical equipment, Canadian Westinghouse Co., Hamilton, Ont., price, each, $1,866; wire and cable, Eugene F. Phillips Electrical Works, Montreal, per car, $123.17; fare boxes, Coleman Fare Box Co., each, $51.10. Thirteen cars are to be constructed, and the cost will be $112,066.

Wood-Working

New Westminster, B.C.—The Brunette Sawmills Co. will build a new dry kiln in place of the one recently burned, the cost is estimated at $4,000.

Memramcook, N.B.—The large woodworking factory and grist mill, belonging to John Gaudet, Memramcook, N.B., was destroyed by fire recently. The loss is estimated at about $20,000.

Building Notes

Sarnia, Ont.—The Schultz Co. of Brantford will build a new school here to cost $58,000.

Simcoe, Ont.—The Board of Education will build two new schools at a total cost of $40,000. Chapman and McGiffin of Toronto are the architects.

Selkirk, Ont.—A new school will be built here. Tenders will be received up to June 24, and full particulars may be obtained from the architect, A. W. Peene, Hamilton, Ont.,

Toronto, Ont.—The T. Eaton Co. propose erecting a factory on Alice Street and Downing Lane. The building will be 227 ft. by 165 ft. and 140 ft. high, having 12 storeys. It will be of reinforced concrete and brick construction, and will cost $625,000.

Parry Sound, Ont.—Tenders will be received up to June 12, 1916, for the erection and completion of a six-room school building to be built in Parry Sound, Ont., for the Parry Sound Public School Board. Plans and specifications may be seen at the office of the secretary-treasurer, Parry Sound, Ont., and at the offices of the architects, Angus & Angus, Angus Block, North Bay, Ont.

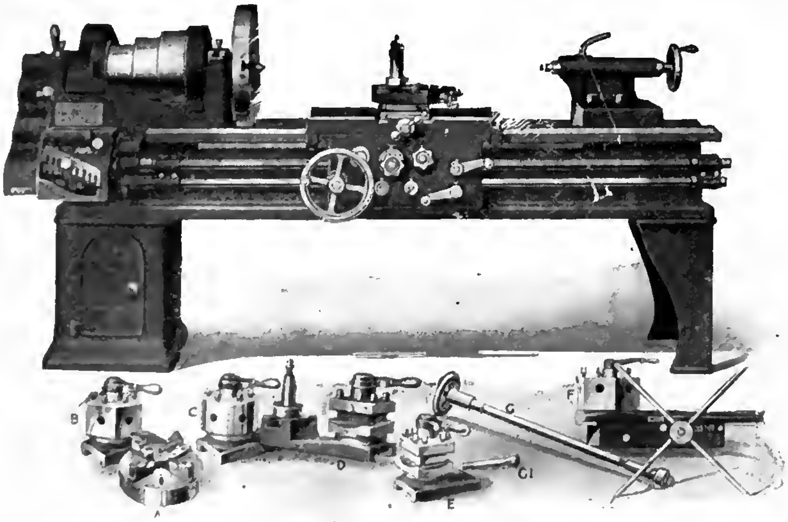
Marine

Car Ferry Sold.—The car ferry, Pere Marquette No. 5, which has been operated between Milwaukee, Ludington and Manistee for the past eight years by the Pere Marquette Line, has been sold to Sydney, N.S., interests, it is announced. The boat will be used on the Bay of Fundy.

Peace River, Alta.—The river steamer "D. A. Thomas" was launched here recently for service between Hudson's Hope and Vermilion, a distance of 600 miles. The steamer is 200 ft. long by 48 ft. beam, and is driven by a 700 h.p. steam engine. She is constructed of B. C. pine, cost $100,000, and has accommodation for 250 passengers.

New Docks for Windsor.—Plans have been submitted to the Canadian Marine and Fisheries Department by the Detroit and Windsor Ferry Co. for new docks at the foot of Ouellette and Ferry Avenues, at a cost, it is estimated, of from $125,000 to $150,000. Work will be started, it is expected, shortly if the Government accepts the present plans, with possibly a few minor changes.

Notice to Mariners.—The following notice to mariners has been issued by the superintending engineer of the Welland Canal:—"On and after the 1st June, 1916, and until further notice, no vessel



will be allowed to enter and pass down through the Welland Canal drawing more than fourteen feet four inches of water, and no vessel will be allowed to enter and pass up through the Welland Canal drawing more than fourteen feet of water."

Halifax, N.S.—It is reported that three shipbuilding concerns have sent inquiries to the Board of Trade as to the property and bonuses available for the erection of shipbuilding plants in this city. The matter will be taken up at once with these concerns, all of which are British. Halifax has been on record for years as willing to give a bonus to a steel shipbuilding plant, and a syndicate of local men is holding a valuable property for such a plant. The local Board of Trade has been advertising this in the British newspapers.

New Incorporations

The Macier Motor Car Co., has been incorporated at Ottawa with a capital of $750,000 to manufacture motor cars and trucks W. K. Cook, F. C. Virtue and F. J. Foley, all of Toronto

The Peerless Pulp Co., has been incorporated at Toronto with a capital of $30,000 to manufacture pulp and paper at Thorold, Ont. Incorporators, Edward P. Foley and J. M. Foley of Thorold, and H. A. Constantine of Niagara Falls, Ont.

The Elmira Planing Mill Co. has been incorporated at Toronto with a capital of $40,000 to carry on business as sash and door manufacturers at Elmira, Ont. Incorporators, W. J. Letson of Woolwich, Ont.; J. Banman and E. G. Martin of Elmira, Ont.

The Wright Furniture Co., has been incorporated at Toronto with a capital of $40,000 to manufacture all kinds of furniture. Head office to be situated at Port Arthur, Ont. Incorporators, W. A. Wright and W. F. Langworthy of Port Arthur, Ont.

The St. Mary's River Construction Co., has been incorporated at Toronto with a capital of $25,000 to carry on business as general contractors at Sault Ste. Marie, Ont. Incorporators, K. McKenzie Wright and J. A. McPhail of Sault Ste Marie, Ont.

The Sorel Shipbuilding & Coal Co., has been incorporated at Ottawa with a capital of $100,000 to carry on business as shipbuilders and repairers, etc., at Sorel, Que. Incorporators, W. H. McKeown, G. E. Chartand, L. C. Herdman all of Montreal.

The Henson Knitting Co. has been incorporated at Ottawa, with a capital of $50,000, to manufacture cottons, jutes,

silks, linens, hosiery, etc. Head office to be situated at Montreal. Incorporators: T. J. Coulter, W. S. Jones, and Richard Booth, all of Montreal.

Catalogues

The York Mfg. Co., York, Pa., have issued a bulletin dealing with their vertical shell and tube steam condenser for ice plants. Copies of the bulletin may be obtained from the Canadian Ice Machine Co., Toronto.

Electric Instruments. — Bulletin No. 100 describes a line of electrical instruments made by the Roller-Smith Co., New York, for signal system testing. Full particulars are given covering each type of instrument and a series of diagrams of facsimile scales are also included.

The Penberthy Injector Co., Windsor, Ont., have issued an engineer's ready reference book for the boiler and engine room. The book contains 21 pages and deals with the "Penberthy" line of injectors, lubricators, "Compodisk" valves, oilers, etc. Each type of apparatus is illustrated and described together with a price list and particulars of each size.

Manganese Chains.—The Jeffrey Mfg. Co., Columbus, Ohio, are now ready to distribute to the trade their latest Bulletin No. 171 dealing with manganese chains. This bulletin contains full details and prices of detachable, "Peerless" and "Hercules" types of manganese chains, sprockets, and attachments, which insure a maximum of elevator and conveyer service in aggravating cases of wear, where the conditions require that the chains and sprockets not only handle gritty and abrasive materials, but come in actual contact with them. All styles and sizes of chains shown in this Bulletin are carried in stock for immediate delivery, while others will be added as fast as facilities permit. Copies may be obtained from the company's office, Power Bldg., Craig street, Montreal.

Classified Advertising Section

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Five cents each insertion when box number is required. Each figure counts as one word. Display rates on application.

FOR SALE

FOR SALE — ONE (1) PLAIN LANDIS Grinder, 10" x 30"; in good working condition. Price reasonable. Apply Canada Forge Co., Welland, Ont. (20)

FOUNDRY AND MACHINE SHOP WITH stove patterns and stock. Splendid opening. Apply Mrs. Thomas Johnston, Kemptville, Ont. (23)

FOR SALE—BERTRAM WAVING ATTACHment for eighteen pounder shells. First class order. Will sell cheap. Lymburner, Limited, Corner Berri and Commissioners, Montreal, Que. (22)

FOR SALE—STEEL WATER TOWER WITHout Tank, 94 feet high. Will support tank holding 13,000 gallons. Cost new $1,600. Will sell for $400, f.o.b. Shawinigan Falls, P.Q. Northern Aluminum Co., Limited. (21)

FOR SALE — ONE NEW FORD SMITH Grinder for Shrapnel. A short time ago we purchased five, find four will take care of our work. The National Manufacturing Co., Brockville, Ont.

1—2-SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

1—C.G.E. TYPE 10—20 H.P. INDUCTION Motor—60 cycles, 220 volts, 45 amps.—1200 R.P.M., complete with Auto Starter. Pulley on Motor 12" Diam. x 10" Face. Cummer-Dowswell, Ltd., Hamilton, Ont.

FOR SALE—2—16 x 2 POWER FEED TURrets; 1—16 x 1½ Turret with threading attachments; 1—16 x 2 Turret; 1—16 x 8 Engine Lathe; 1—12 x 8 Tool Lathe; 1 Speed Drill. Apply J. A. Harvey, 16 Pearl St. (21)

FOR SALE OR RENT—MACHINE SHOP AND foundry, with garage. Good machinery, good locality. Lots of cars and boats. Power and rent very cheap. Box 334, Carleton Place, Ont. (21)

FOR SALE ELECTRIC GENERATOR TO run 80 lamps, 110 volts, 300 r.p.m., including switchboard and indicator, in good condition. Richards-Wilcox Canadian Company, London, Ontario. (23)

FOR SALE—POND PLANER 26 X 26 X 7 ft. table, complete in all respects and as good as new, big bargain. Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE EXCELLENT PLANT FOR THE manufacture of electric passenger and freight elevators, patterns, drawings, blueprints, special and ordinary machinery and parts. We are instructed to offer this entire plant at a fraction of the cost. If you are looking for a splendid manufacturing proposition, write for particulars of this one. Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY
970 Queen St. West, Toronto (15)

FOR SALE

TWO ENGINE LATHES FOR SALE—ONE a 18" x 10' McKechnie & Bertram; the other other a double-end pulley lathe 18" x 10' between face plates; both ends completely independent; very suitable for cutting off base and open ends of shells. Turnbull Elevator Mfg. Co., Toronto. (22)

FOR SALE—COMPLETE MACHINE SHOP, fully equipped and working, in good city: low rent, cheap power: plant includes five lathes, Universal milling machine, grinder, etc. Will entertain partnership with practical man who has cash to invest, or sell outright. Box 201, Canadian Machinery. (21)

FOR SALE—NEW HAVEN, 60-INCH SWING Standard Engine Lathe—triple geared. 15 ft. bed, hollow spindle, cuts threads 1 to 12. Compound rest, countershaft, steady rest, wrenches, etc. This tool is in excellent shape and owner offers special bargain. Particulars from Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE — TWO GOLDIE-McCULLOCH Wheelock Engines—cylinders 16" diameter, 38" stroke; both engines now running, but will be replaced with Hydro-Electric. Engines guaranteed to be in perfect condition, and will be sold complete with belt wheels, one 14' x 35" face and one 12' diameter with 24" face, also belting if required. Canadian Consolidated Felt Co., Berlin, Canada. (19)

WANTED

WANTED BERTRAM WAVING ATTACHment for 4.5 Shells, with or without Lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson Limited. (R.T.F.)

ENGINEER WANTS AGENCIES FOR MONTreal and district. Side line or specialties, on commission basis. X.Y.Z., Canadian Machinery, Montreal. (19)

WANTED — BERTRAM WAVING ATTACHment for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

BOILERS WANTED—TWO SECOND-HAND, about 150 H.P.; at least 80 pounds working pressure under Ontario Government Boiler Regulations. Give full particulars, Box 198, Canadian Machinery. (19)

REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

WANTED

Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN LAMP FACTORY
ST. CATHARINES, ONTARIO

SITUATIONS WANTED

LARGE SHELL MANUFACTURERS — MEchanical engineer with shop, designing and executive experience with prominent Canadian quantity producer of 9.2". At present employed. Best of references. Address, in confidence, Box 200, Canadian Machinery. (21)

PATENTS

THE PROPRIETOR OF LETTERS PATENT No. 126215, relating to "pump device," desires to dispose of the patent or to grant license to interested parties at reasonable terms, with a view to the adequate working of the patent in Canada. Inquiries to be addressed to the patentees, Aktiebolaget Ingeniorsfirma Fritz Egnell, Stockholm, Sweden. (21)

SITUATIONS VACANT

WANTED—FOREMAN TO TAKE CHARGE of Brass Foundry. Apply with full particulars. Box 203, Canadian Machinery. (21)

WANTED—YOUNG MAN TO HANDLE ADvertising of a line of engineering equipment. Must be prepared to locate in a city of 15,000 population. Salary to start, $70 per month Box 184, Canadian Machinery.

MECHANICAL SUPERINTENDENT WANTed—for plant of the Starr Manufacturing Co., Limited, Dartmouth, Nova Scotia (near Halifax), operating one 10-inch and one 18-inch train of rolls, producing merchant bar iron. Manufacturers of ice skates and bolts and nuts. Address the company direct, stating age, experience, salary required, giving references, also when services will be available. The Starr Manufacturing Co., Limited, Dartmouth, N.S. (22)

IF what you want isn't advertised in this issue, consult our Buyers' Directory, Page 73.

INDEX TO ADVERTISERS

Producing 4.5 in. Shell Billets in Electric Furnace

Staff Article

In the production of munitions an impetus has been given the establishment of the electric furnace in metal-working industries that under normal conditions would probably have taken some years to realize. The installation described refers to one only of a number of Canadian plants similarly equipped, and serves to indicate a development in steel-making that is to-day making rapid strides in Great Britain, Europe and the United States.

TO augment the production of steel billets for the larger shell forgings, electric furnaces are now being extensively employed, and, where properly operated, the results compare very favorably with those obtained by the open-hearth process. The successful manufacture of steel ingots or castings by the electric furnace method is now assured, the quantity output being governed entirely by the capacity of the furnaces installed and their power consumption, and the quality of product by the skill and experience of the operators. To convey to the reader some conception of the various details entering into the production of 4.5 in. shell billets is the purpose of the accompanying article.

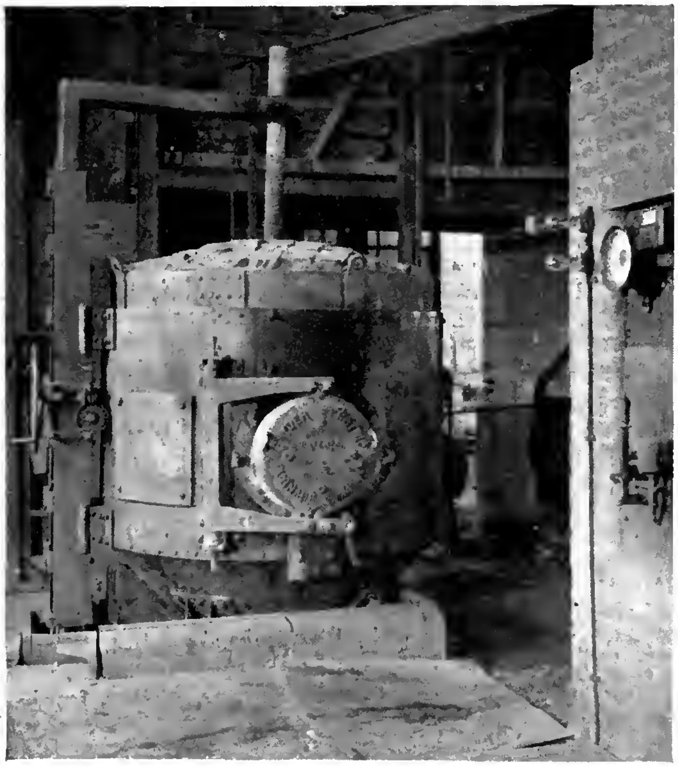

FIG. 1. SNYDER ELECTRIC FURNACE INSTALLATION.

Charging the Furnace

As soon as the melted charge has been poured into the ladle, the furnace is tilted back to its vertical position, and the operation of recharging is immediately proceeded with so as to avoid any unnecessary loss of heat.

The first detail is to insert a new contact piece in the bottom of the furnace. This is done by means of a long pair of tongs, the workman's head being encased in a special hood fitted with a thick colored glass, to protect his face and eyes from the intense heat and dazzling light of the fire chamber. When this lower contact is in place the upper electrode is lowered to test the arc. The furnace is now ready for recharging, and the proportions of material adopted in the particular plant here described, in order to obtain the grade of steel necessary to meet the shell specification, are as follows:—60 per cent. shell ends; 10 per cent. wrought iron and steel turnings; 10 per cent. baling wire scrap; and 20 per cent. sheet steel scrap in bundles.

The shell ends and turnings are first thrown in and reduced to a molten state; during which process it is necessary for an operator to be continually at the electrode adjusting wheel, shown at extreme left of Fig. 1. The brilliancy of the two lights on the wall, to the right, indicate to the operator the action of the arc within the furnace, and the wattmeter on the wall records the power being consumed. When the shell ends and turnings have been reduced to a molten mass, the wire scrap and baled sheet scrap are added.

The time required to melt a charge of approximately 2,800 lbs. (the capacity of the ladle), is from $2\frac{1}{2}$ to 3 hours, but in the case of a first charge, where the furnace has been allowed to cool down, 4 hours may elapse before the metal is ready to pour.

When the metal is about ready to be poured, the melter makes a test of the charge by drawing off a few pounds by means of a long handled ladle, inserted through the charging door. This is poured into a small cast iron mould about 5 inches long and $1\frac{1}{4}$ inches square. After it has set, it is cooled off and broken apart for examination as to fracture and carbon content. If the carbon be found to be below the requirement, sufficient material, rich in carbon, is added, following which, in due course another test is made. It, however, sel-

FIG. 2. TAPPING THE FURNACE INTO LADLE.

dom requires more than two tests to bring the mixture to within the limits of the specifications. When the experienced eye of the melter indicates that the charge is ready to pour, no time is lost in doing so.

Pouring and Filling the Moulds

When tapping the furnace the ladle is placed under the pouring spout, and by means of underground mechanism, the furnace is tilted upwards as shown in Fig. 2. This movement is so arranged that the pouring spout remains practically stationary, it being the approximate centre on which the furnace pivots, while being tilted.

As already stated, the charge averages about 2,800 lbs., this being the capacity of the large ladle. When the ladle has been filled, the surface is lightly covered with floor sand, to minimize heat loss through radiation, and also protect the workmen. As shown in Figs. 1 and 3, a monorail is located in front and above the furnace, by which the ladle is taken to a position above the revolving table, which carries the ingot moulds. To prevent any possibility of injury to the operators through splashing of metal, the various levers which control the ladle mechanism are fitted with long extensions. Once the pouring nozzle is brought into position it is seldom necessary to shift the ladle further, as the forty ingot moulds are so arranged that the revolving platform on which they are mounted brings them under the ladle in regular rotation. The table is easily revolved by one man, using a length of pipe placed on levers situated at eight points around the platform. The design of the table is shown in the line sketch Fig. 4.

Imbedded in the concrete foundation A, is the shaft B, which extends up to

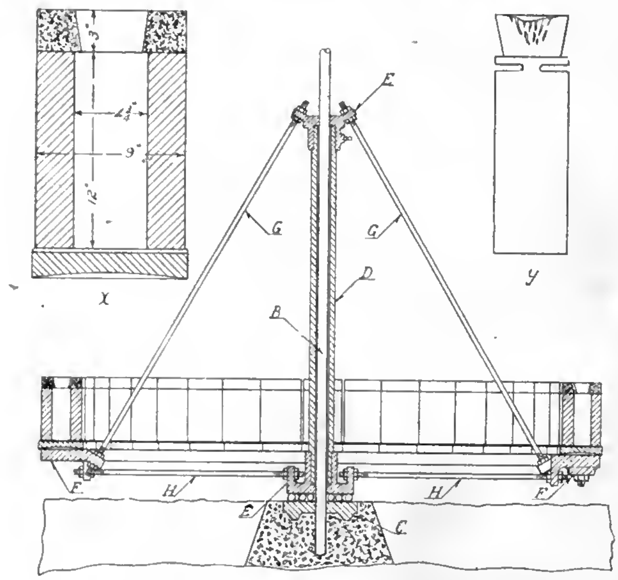

FIG. 4. INGOT MOLD, BILLET AND REVOLVING TABLE ARRANGEMENT.

the ceiling and is secured to one of the joists. About this shaft and resting on the foundation is the heavy thrust plate C, upon which the entire apparatus with the moulds, revolves. The framework consists of the centre column D, upon which is secured the two flanges E, the eight-piece platform F, being supported by means of the eight oblique stays G and the horizontal stays H; the whole revolving on the balls shown. An enlarged sketch of the mold and billet is shown at (x) and (y). It is usually found that the last billet poured, or possibly the last two, will not pass inspection, owing to "pipes" being formed by slag or chilled metal, etc.

Refitting the Ladle

When the last of the metal has been run out of the ladle, the latter is placed on the floor in a horizontal position and the stopper rod dismantled. It is allowed to cool, after which a new nozzle is placed in the bottom and a new graphite stopper on the rod. If necessary, new graphite sleeves are also inserted, but as these are not subjected to the running action of the molten metal they are generally good for a number of heats.

For about an hour before each cast, the interior of the ladle is kept hot by the flame of a strong fuel oil burner. This, of course, is usual practice, and is necessary, to avoid chilling the molten metal, when drawn from the furnace.

Preparing the Moulds

After the billets have solidified, which generally takes about ten minutes, the moulds are taken from the table and the billets removed. The metal shrinkage is usually sufficient to allow the billet to drop out freely, but in any case a light blow with a "sledge" ejects it. The ingot moulds are of grey iron bored and faced to the dimensions shown at x, Fig. 4; and have a life of from 80 to 100 casts, although often beyond this. The base plate is of grey iron, faced on the upper surface, and, to insure a good joint, a disc of felt paper 1/4 inch thick is placed between the mould and the base plate. Before the next charge is ready to be tapped, the moulds are again assembled in position on the platform of the revolving table.

Inspecting and Cutting to Length

The billets from each heat are marked with a serial number, and are taken to a Hall cutting-off machine where the top is cut off, leaving a length of 10 1/4 inches. The specifications call for a section approximately 20 per cent. of the cross sectional area of the billet being left at the centre for fracture and carbon inspection. Some drillings are also taken from each heat for laboratory analysis.

FIG. 3. CASTING 4.5 SHELL BILLETS IN INGOT MOLDS.

WINTER LIGHTING ATTENTION IN SUMMER

AS a rule manufacturers are more interested in lighting during the winter months than during the summer, prin-

cipally due to the fact that the lighting conditions in their plants are then forcibly brought to their notice.

The manufacturers of lighting equipment have, however, been endeavoring for some time to impress upon superintendents and managers of plants that the time to make changes, revisions or repairs in the lighting equipment is during the summer months, and that this work should be started early. Just after the winter season the superintendent or plant manager has clearly in mind his experience with the lighting system during the short and dark days, and it is, therefore advisable for him to make plans for the revision of the system, which can be carried out during the months when artificial light is seldom needed.

We find as the years go by, that the lighting season, so-called, is not as clearly defined a period as it was a few years ago, and that there is considerable activity during the summer months for industrial lighting.

METALLIC MAGNESIUM

MAGNESIUM is one of the several metals which the present war has proved to be of great value. As with numerous other products, before the war, France, Great Britain and the United States were dependent on Germany for their supplies of this material. The price was steady at about $1.45 per lb., but rose from $2.50 shortly after the beginning of the war to as high as $7.50 per lb. The price now is about $5.50 per lb.

The chief uses of magnesium are:—Scavenging alloys for making denser, cleaner, stronger and more homogeneous alloys; illumination, as in military uses for shrapnel trailers, star bombs, flare lights, etc., and in photography for flash lights.

Uses of Magnesium

In aluminum castings 2 per cent. of magnesium cleans up the aluminum, almost doubling its tensile strength, quadrupling its resistance to shock or jar and reducing the cost of machining by more than 50 per cent. This is of great importance in connection with the construction of aeroplanes and dirigible motors, high-speed engines of every type, and in all machinery or structures where strength, with a minimum of weight, is required.

Metallic magnesium is usually recovered by the reduction of the chloride, but it can also be obtained from the reduction of the oxide or carbonate. The common magnesium carbonate rock is known as magnesite. Deposits of this material occur in a limited area in the township of Grenville, Quebec. The production in 1915 (including some calcined), amounted to 14,779 tons, valued at $126,535, in striking contrast with a yearly average production from 1908 to 1914 inclusive, of 621½ tons. While the known deposits are limited in area, there is every possibility that the district contains other workable deposits. Float magnesite has been found over a wide area. Magnesite is also found in Yukon and in the Cariboo district, British Columbia.

The highly refractory quality of magnesite and its ability to form a hard vitreous body when combined with magnesium chloride has led to its adoption for a number of purposes. The largest consumption is in the manufacture of magnesite firebrick, crucibles and in bedding steel furnaces. It is mixed with sand, sawdust, ground quartz, talc and other substances in the manufacture of tile, flooring, roofing, artificial marble, wainscoting, etc. Magnesium bisulphide is used in digesting and whitening wood pulp in paper mills.

PATTERNS FOR THE SMITHY

WHERE there is a fair amount of repetition work done in the smiths' shop, the practice of having patterns is altogether a desirable one, as with these errors of working can be avoided. Generally speaking, such patterns should be of the exact size and shape of the forging as it leaves the hands of the smith, and not that of the finished article after machining and fitting. The former gives what might be called a limit size to the workman, and will diminish the weight of the stock used. Indeed, provided a good smith is in charge of the shop, and there are proper facilities for storing and displaying the reserve of stock at the command of the workmen, the use of patterns will make possible the utilization of short ends without wasting time, because the eye can better gauge what is wanted from a pattern or model than from a rough drawing and a few figures, which show the principal dimensions only. To provide him with such patterns does not cast any reflections on the workman's skill any more than it does in the case of a moulder's pattern. As a matter of fact, very many moulders could make moulds in sand without patterns, but that would not be a profitable way of working, unless in a few well-defined cases.—Practical Engineer.

BY-PRODUCT COKING OF COAL

THE great development of by-product coking of coal in Germany has assured her an uninterrupted and adequate supply of modern explosives. The value of this development may be measured by the importance of munitions in deciding the outcome of the war.

In the past the whole world has been dependent upon Germany for dye-stuffs and other substances prepared from the derivatives of coal tar. Thus both in peace and war Germany possessed a great industrial advantage over other nations.

British plants are now being established to cope with the demand for picric acid and trinitro-toluene, while the United States is also profiting by the lesson learned from the war. Before the war there was but one company in the United States producing distillation products on a large scale, while the latest statistics show that over 8,000,000 tons of coal were carbonized in by-product ovens last year, yielding over 4,800,000 gallons of benzol and 1,300,000 gallons of toluol. The full annual capacity of the benzol recovery plants now in operation and in course of construction is estimated to exceed 20,000,000 gallons.

Although Canada has the third largest reserves of coal in the world, beehive coke ovens, wasting the by-products, are still used in some sections and not a single additional by-product oven has been installed since the war. The war should teach Canada the obvious lesson that, whether for war or peace, it is criminal folly to neglect the utmost utilization of those resources which are lying latent in her bounteous supplies of bituminous coal.

SHIPYARD AT VICTORIA, B.C.

THE immediate benefit which Victoria will derive by reason of the passage of the Shipping Bill, recently approved by the Provincial Legislature, has been demonstrated in the completion of negotiations between the Provincial Government and the Cameron & Genoa Mills Shipbuilders, for the lease by the latter of two acres of waterfrontage property on the west side of the inner harbor, just south of Point Ellice bridge, whereon will be erected a modern shipbuilding plant. Work on the building of two ships will commence at once. Two ships will be laid down as soon as the facilities are ready and the company has assurance that it will receive contracts for two more. When the yard is in full operation it will give employment to 300 men, of which a large proportion will be skilled.

The company anticipates that fifteen wooden vessels will be constructed within the term of the lease of the shipbuilding site from the Provincial Government on Songhees Reserve. The type of vessel to be constructed will be a standardized carrier of a capacity of 1,500,000 feet of lumber and will cost, with machinery, approximately $170,000.

The Canadian Fairbanks-Morse Co., have been awarded a contract for a 75 h.p. gasoline motor and a "Goulds" centrifugal pump by the town of Orillia, Ont.

MACHINE TOOL EVOLUTION

By A. L. Haas

SPECULATION on the subject of the ancestry, direct parentage, the prior and eventual evolution of the machine tool possesses more than mere interest or antiquarian curiosity. With the question is bound up the entire past of the mechanical industries, the present practice and the future progress of the world, that is as far as lies along mechanical lines.

Every industry is economically dependent upon the machine tool; practically every article of consumption owes a considerable although perhaps indirect debt to the series of machines so known and classified.

When Maudsley first conceived and applied the slide rest to the lathe he created a minor industrial revolution. From the slide rest has sprung all the allied machines which to-day comprise the equipment of the modern shop. Maudstey's slide rest forms the foundation, nay the underpinning of all the means of transport, taking only one field of engineering activity. The motor bus seems a strange descendant of the slide rest parentage, but rightly considered such is the ancestry of this popular and democratic means of transport.

The Lathe the Pioneer

The lathe, easily the king of the whole proletariat found in use to-day cutting and shaping metals, has experienced strange vicissitudes in its evolution. No doubt the very earliest form is that still in use in the Levant. Among the trophies brought home by the tourist to Egypt and the Near East are frequently screens and other articles of wood made up almost entirely of small turned pieces. The operator, whose limited kit, including his lathe, is carried about on his person, squats in a convenient corner and thrusts two pieces of wood having metal centres into the ground. A bow with loose string forms the motive power, the string being placed one turn round the work. A chisel held between the toes for rest, forms the cutting appliance. The bow is moved ceaselessly backwards and forwards with the left hand, while the right hand and the toes, which having never known footgear are very flexible, manipulate the chisel. The device is possibly as old as the potters' wheel, which is still in use at the present day in a form similar to that of classic Greece. While the only change in the potter's wheel is to make the entablature of metal, and drive it by power, its ancestor, as in the case of the modern lathe, could not possibly be expected to recognize its descendant. The engine lathe of only 50 years ago bears little resemblance to its direct outcome, the 4-spindle automatic, and the question becomes pertinent if we have yet reached the ultimate outcome in complexity.

Cast Teeth Obsolete

It is only yesterday, so to speak, that toothe wheels were the product of expensive patterns, and the inaccuracy of the foundry was corrected by means of a file when assembled, when 1-10 depth of tooth was a minimum of clearance to allow for irregularities. It led to the long tooth form now discarded. In the case of large drives, in view of the unearthly racket made by metal teeth, hornbeam teeth fashioned by the patternmaker and millwright were the only solution.

To-day the cheapest lathe on the market has quiet running true form teeth, cut from the solid blank. All things considered, they are actually cheaper than the foundry made article. It is probable, so universal have machined teeth become with their minimum clearance and quiet running, that few foundries ever get the job of casting toothed wheels. Damp sand and molten metal are scarcely ideal materials for an accurate product.

The gear cutter in its first inception was a hybrid with the milling machine for one parent. Subsequent to the introduction of the slide rest on the engine lathe and all it involved, the milling cutter and its possibilities marks the beginning of the second epoch in the machine shop. Yet even so the planer and shaper have not been displaced and for accurate work seem likely to survive.

To take another instance, the planer, engine lathe and column drill seem the likeliest ancestors for the boring mill. It has always been a debatable point whether great occasions produced great men or whether the contrary was in fact the case. Both sides of the argument have their partisans, and the truth may lie somewhere between the two extremes. Such is its usual habit. In like manner whether demand creates supply, or supply demand, forms a similar debatable point. In the question of machine shop evolution, it would be worth study as to whether the advances made were in response to necessity or forestalled it. Certain it is that many of the everyday products would have been simply impossible to produce had the machine shop lagged in the rear.

Action and reaction take place between tool and product. The speed change on the modern lathe and on the motor car bear a striking resemblance. In this case it may be assumed that the necessity of the car led to its adoption on the machine tool. At least machine tool makers were not slow in following the lead given if the assumption made is correct.

High Speed Steel

The greatest impetus of all of recent date is that given by high speed steel. There was always the precedent of the burglar and the safe. Sometimes the safemaker had the burglar fixed. An enterprising thief came along and safes had to be re-designed to suit new conditions of attack. The same rivalry holds good in the duel between the armor plate and the gun. In the case of high speed steel so novel were the conditions created that re-design became universal . Many makers in a vain effort to be up-to-date wasted tons of pig iron simply increasing weight without due regard to effect.

One curious point calls for notice. In the personal observation of the writer, many old type English tools when tested and in many cases without any strengthening, were found fully capable of dealing with the higher speeds and feeds of the newer steels. In one structural yard a battery of quite antique drills are running to-day at speeds and feeds which would have been considered miraculous by their designer, and are giving first rate results. The clumsiness and abnormal weight often criticised in English designs had a real and tangible value under the new conditions created by the modern steel.

Few structural yards or boiler shops, decently equipped, ever punch a hole now. It is cheaper to drill with corresponding advantages to the twist drill maker and the machine tool builder, and with considerable benefit to their product.

A case where demand certainly led supply is that of the steam turbine. Makers of machine tools were called upon to furnish machines of hitherto undreamt of size and abnormal weight even for their dimensions. The prob-

lem caused some troubles incident to both factors, while high speed steel added to the burden. One of the chief benefits afforded was in the ease of returning locomotive types, always a troublesome and very slow job. Grinding conferred a distinct benefit in realty obstinate cases, but the new steels made speeds possible only in the dreams of former superintendents. It would not be surprising to learn that the problem of low tyres spurred the metallurgist on in the provision of a capable tool steel.

The lathe may be considered as the ancestor of the column drill, in fact the type of back gear in some of the older type drills is of equal strength and similar to that in a lathe. It was undoubtedly the lathe which has influenced design more than any other single tool hence the honor due to Maudsley.

Using the language of the horticulturist, hybrids and sports are being evolved continuously, some for special purposes, others in the expectation they will be a permanent addition to the machine tool trade. All new machines have been so regarded at the beginning of their career. Who would have thought that the modern broaching machine would develop in the manner it is doing, for special work certainly, but as a regular purpose machine one might have been dubious not so long ago. As for grinding, battles were fought in the technical press over the matter, yet the grinder, cylindrical and surface, has not merely come to stay, but has created a distinctive place for itself, and relegated much of the former skill of the mechanic to the scrapheap.

Geometric Limits of Machine Work

As a general proposition, machine tool builders, or, if you will, the entire engineering trade, are interested so far as manipulation is concerned in the production of circular, helical, straight line and surface work. Other geometric forms seem foreign and are in the main distrusted and in nearly every instance are former-made, not generated. The influence of the earlier limitations of the craft are existent to-day: Circle, straight line, surface and screw, which last is after all but a coiled straight line. There is virtually no generation of a helical form from the straight line although this has been repeatedly performed. It is easier and more direct to copy. Yet a practically perfect helix may be generated from a straight line motion. An inclined straight line guidance with equal increments of motion should give a nearer approach to accuracy than 1-100 inch per foot lineal in lead screws.

It may not be out of place to point out that two wires of equal diameter coiled on a solid round has given a very exact form of thread for pitch when one is removed. This method of screw making was practised in the Far East when the Western nations were barbarians. Leonardo-da-Vinci, the medieval Italian painter, was an engineer of no small genius, and his records left in the form of sketch books prove that he foreshadowed many modern developments in the cutting and shaping of metals.

The lathe progressed from the bow to the pole for motive power, to the treadle, and thence to the power drive. It achieved a slide rest and a lead screw, put on changewheels and self-acting feed. From thence it developed backgear and geared feed box. Subsequently the fast headstock was in one form given a transverse motion. In another a drum with cams appeared below the bed and the automatic was out. Its power equipment is frequently now self-contained and a variable speed motor gives an even wider choice of feed and speed than its mere construction affords.

Future developments may set the armature of its motor in place of the back gear spindle, and movement of a switch grade in an infinite manner its range of speed. The electrical drive of the planer with the reversing motor and contacts shadows quite an electrical revolution as to power. A boring mill used for facing with a variable speed motor like the lathe may be controlled for feeds and speeds outside the operator's judgment by electrical contact, increasing speed as the tool approaches the centre and so give a uniform cutting speed.

The hand hammer universally 2 lbs. in weight has diminished to ½ lb. and is used now merely for marking off in many shops. For many purposes the file has been abolished as well as much smiths' work.

Modern welding has provided that standing joke of some years ago, a competent putting on tool. There will certainly come the time when the leather or other belt will be conspicuous by its absence and long lines of shafting be abolished.

A Possible Bearing Material

There seems no reason why cast iron having a hard even if rather brittle face should not be used for wearing surfaces. Chilling is one method, but the production of a carbide surface and grinding methods may ultimately give us an almost eternal wearing surface. Accuracy will then be, as in the case of slides, of durable maintenance.

In the consideration of future possibilities with regard to surface and slides, the question of surface grinding from the rough casting must not be lost sight of. Chilled rolls are being made by grinding from the rough and while the production of an approximately accurate surface of the highest character is still the function of the scraper, a surface of considerable accuracy may be produced utilizing modern grinding methods from very hard material. For example, it is not outside the present range of possibility to cast a lathe bed with almost dead hard surfaces; such a bed, finished by grinding would retain its accuracy over very long periods of time. The saddle which wears equally could if necessary be of ordinary material.

Scarcely any manufactured article has made such strides in recent years as the machine tool. To glance over catalogues only twenty years old is to be transported into another world altogether, a world where output received less consideration, and a less strenuous existence was in vogue..

Existing Tendencies

Two tendencies seem to exist, which are interdependent; an increase in complexity demanding greater skill and a return to simplicity on the score of capital cost. There is always the factor of the labor to be considered. Machine tools are being now built demanding increased skill, also others whose deliberate intention is to utilize skill of a less pronounced order. Complexity is by no means toward a demand for greater skill; it is in many instances introduced for the purpose of employing the simple operator dependent upon another for setting up and supervision.

Thus it is possible and seems a contradiction in terms, but is none the less a fact, that the least skilled labor demands the greater capital. In this wise caution is necessary. Skill consists in the production of good work by inferior means, want of skill demanding nearly perfect implements and machines almost automatic in their operation. The conflicting factors are many, the objects desired diverse, and it is by no means an inferior intelligence which can sum up the issues involved and decide between them.

Most progress consists in alternating periods of acceleration and retardation, the general direction being forward but in a series of waves. A new metallurgical discovery, a new adaptation, a fresh process and for the moment all previous practice seems to be in danger of the scrapheap, in actuality such a catastrophe is never imminent and most things survive but in a more limited sense.

The writer recently came across a Whitworth lathe dated 1840 No. 9, in quite good and usable condition, also in another locality a Muir shaper, no date, but from general design of the same period in good condition and at work.

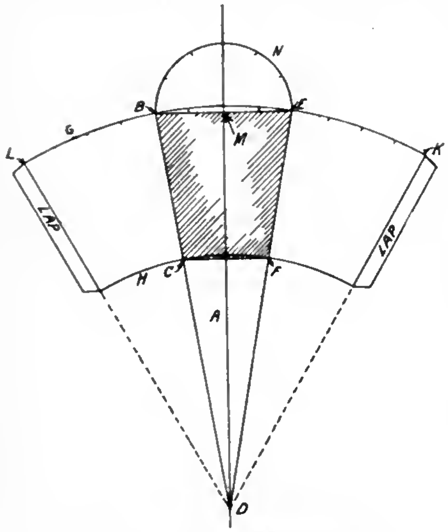
The interest in the ancient is pertinent to the matter of evolution, in the matter of machine tools, those of con-

siderable age are apt to provoke a smile since their design seems childish and elementary in form. Yet it is not sure we have any right to be moved to mirth, in their day they represented advanced practice as in turn the design of to-day will cause equal surprise to future generations. It is more a matter of wonder that they so closely resemble the tools of to-day. The modern express passenger engine is in essentials but not exact detail, on the plan of the "Rocket," and the lathes of 75 years ago in the same manner resemble the product of to-day.

A FOUNDRY LADLE STORY

By J. R. Tate

A SHORT time ago, I was traveling west, and being held up at a small town junction for a few hours, took a stroll around. Noticing the stack of a cupola, I naturally turned my course that way, so the side door being open, I walked up and stood looking into what seemed to be a blacksmith's shop. Two men were



DEVELOPING SHAPE OF SHEET FOR A FOUNDRY LADLE.

working there, one a blacksmith, and the other evidently a handy man. Taking me for a traveler, they paid little attention to me, outside of pointing to the further end of the shop, when I asked where the foundry was. Before going through, I noticed that the two men were working on a large new ladle and were also having trouble with it.

Offering Assistance

I walked on, and while standing at the foundry door, could hear the conversation of the men at the new ladle. It seemed that the foreman had gone away several days before, and had left instructions for this ladle to be made to certain measurements, and they were both about stuck on the job. The moulding shop did not interest me, so I decided to try and break in carefully on the two men. You know how it goes when a fellow comes into a foundry, all dressed and prettied up, he don't fit somehow, and I felt that I would be better fitted if my dollar shirt, etc., were replaced by my working clothes. However, sauntering back as though going out, I stopped beside the ladle over which the men were having a conference.

"Making a new ladle, boys?" I ventured. "Yes," answered the blacksmith rather shortly. "Rather a difficult thing to make too," I again ventured. "We're the ones as knows it," chirped in the helper.

"Do you know?" said I, "I helped a fellow once to make a ladle and I believe I remember how he did it, yes sir, I believe I do." Pulling out my watch, I said, as though they were old friends of mine, "I have just fifteen minutes to spare boys, now what do you say, if I just turn in and help you two fellows," at the same time reaching for a couple of cigars, which they very naturally connected up to.

"Well," said the blacksmith, "if you can tell us how to lay out a ladle that will measure up to these figures, we will certainly smoke to your health," and he started right in to smoke it, before I had a chance to make good.

Making Good on the Job

The size of the ladle required was as the sketch read 30 inches by 28 inches by 17 inches, being 30 inches deep. We figured out the correct shape as follows, incidentally we drew it out on the concrete floor of the shop. The first line was a straight one as marked A in sketch. We then drew a full-sized sketch of the ladle, required as indicated in shad- portion of cut, and placing a straight edge so that it would touch the points C and B. Next we drew a long line continuing it until it touched the former line A, as at D in cut, repeating the same method at E and F. From the point D all the other measurements were worked out. Taking a piece of string and getting the blacksmith to hold one end of it on point D, I took a piece of chalk and wound the string around it at a point which would permit the chalk to touch points B and E, then we had a large compass with which we struck a line as indicated at G, and shortening up the compass, we also struck line as at H, which line touched points C and F as in cut.

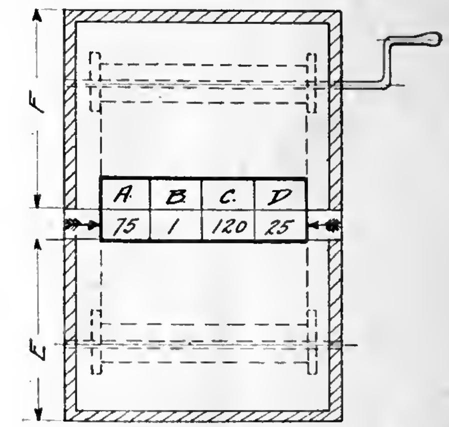
Having this much done, the next problem was to find out how long the strip of metal would have to be to form a ladle 28 inches in diameter at the upper end. Our method was as follows: taking point M as a centre we struck a line as marked N, this line really represents one-half of the upper end of the proposed ladle so, by taking a pair of dividers and stepping the half-circle off into equal parts, we had the distance it was around half of the top of the ladle. It was only necessary now to mark off the same number of spaces on each side of line A, as stepped off in cut, thus if there be six spaces to line N which represents half of the ladle, there will be twelve spaces in line G, which must reach all the way around the ladle. Having ascertained the length of the upper end of strip, a line was drawn from points K and L to the point D, after leaving enough for lap at each end of the strip.

We now had the exact shape to which the sheet must be cut, to form the ladle required. I have described the method in detail, that the laying out of any size ladle may be easily understood. First a cut of the ladle at top end of lineA, then from point D work out the rest, as we did. Your cut of ladle will always control the position of point D. Work out a small one in paper, it is good practice.

NOVEL MILLING MACHINE DIVIDING HEAD TABLE

By J. H. Moore

THE dividing head table shown in the accompanying illustration is designed to fill a much felt want by operators of milling machines. The writer feels sure that operators will agree with him on this point, as what is more confusing than the attempt to pick out a line of numbers



NOVEL MILLING MACHINE DIVIDING HEAD TABLE.

from a mass of same, such as are found on the usual type of dividing head tables. It takes considerable concentration of mind, and, even then, one is apt to make an error, especially after the list is well thumbed and soiled in use. The table shown can be made from any box of convenient size, and such as comes to the plant with large sizes of taps. The spools are quite an easy matter to get.

Little else is needed except that the box has a glass or mica front. The spaces (E) and (F) are painted black, while the remaining space is left transparent to show the numbers as they appear. Spaces A, B, C, and D are printed as follows:—(A) has number of teeth printed on space; (B) has number of turns to handle printed on space; (C) has gear on handle printed on space; (D) has gear on worm stud printed on space. By turning handle you can get any combination desired, and can see the complete line of numbers at once.

Safety Rules for Iron and Steel Manufacturing Plants

Selected

The State of Ohio has drawn up the accompanying Code of Rules and Regulations with a view to their adoption by the management of Blast Furnace, Coke Oven, Steel-making and Rolling Mill Plants, within that territory. From a study of the proposals, not a few of the suggested enactments may be worth while of appropriation by similar institutions in Canada.

THE Industrial Commission of Ohio has formulated a code of Safety Rules and Regulations governing the operation of blast furnaces and steel plants and has published them in pamphlet form. A similar code proposed by the same commission relates to foundries and to the employment of women in core rooms. These sets of rules, as prepared by sub-committees, have been approved by a general advisory committee, but have yet to be approved by the Industrial Commission. They are being sent to foundries and steel plants in Ohio and about two months' time will be allowed for the receipt of criticisms and suggestions from operating companies. The proposed regulations for blast furnaces and steel works are as follows:

By-Product Coke Ovens

1.—Hoppers should be guarded in such a manner as to prevent man from falling.

2.—Exposed moving parts of coal and coke handling machinery to be guarded as prescribed by general code. (It is recommended that grease cups be extended to the outside of the guards to facilitate oiling.)

3.—Some method of shutting off power to be installed near coal hoppers to enable workmen to shut down hopper shakers in case of accident.

4.—All approaches leading to rooms or buildings where coal dust or gas may accumulate to bear warning signs forbidding smoking or open lights.

5.—All elevated walks, stairways and platforms to be guarded by standard railing. (Note exception under Rule 6.) Would recommend that "standard railing" be specified as follows: To be not less than 3½ ft. in height, with intermediate rail midway between top rail and floor, and shall have toe-board or toe-plate at base at least 3 in. in height.

6.—Exception to Rule 5 to be made for platforms at both front and back of coke ovens.

7.—Quenching cars and larry cars to be equipped with automatic warning signals.

8.—All power transmission machinery to be guarded by standard guards.

9.—Reversing machines and counterweights on oven platforms should be enclosed by solid or mesh guards.

Blast Furnaces, Docks and Ore Storage Yards

Section A.—General:

1.—These rules are intended to cover the fundamental safety requirements for blast furnaces, cast houses, stoves, gas cleaning apparatus, skip hoists, pig casting machines, stock houses and stock handling machinery.

2.—Valves, switches and operating levers that control the movement of machinery covered by this code shall be provided with devices which will permit them to be locked.

3.—Standard platforms, provided with permanent stairways or iron ladders, shall be installed at all elevated points where employees daily or frequently are required to go. This rule shall not apply to railroad structures.

4.—Some means for the quick resuscitation of men overcome by gas shall be provided at the blast furnaces.

5.—A signal system shall be maintained between each blast furnace and its blowing engine room.

Section B.—Blast Furnaces:

1.—Each blast furnace shall be equipped with a telephone or speaking tube connecting the top of the furnace with the cast house or blower's office. It is also advisable to have a means of quick communication between the cast house or blower's office and skip hoist operator's house.

2.—A removable shield constructed with a hole for the movement of the drill shall be provided when tapping the iron hole.

3.—The mud gun shall be equipped with a funnel shaped guard at least 6 in. high around the receiving hole of the mud cylinder.

4.—For all new construction, explosion doors on top of the furnace shall be of the bleeder type only, and so constructed as to prevent, as far as possible, the escape of anything but gas and fine material.

5.—Platforms shall be provided for all bleeder valves, and wherever practicable such platforms shall be standard.

6.—Bustle pipes shall have a railed walk with toe-boards and shall be equipped with stationary stairs or steel ladders.

7.—Provision shall be made to protect persons underneath the skip car tracks from falling material.

Section C.—Stoves:

1.—Means shall be provided so that before men are permitted to enter stoves for any purpose, the cold blast and gas burner valves must be locked shut, the chimney valve locked in proper position and the operating mechanism to the hot blast valve disconnected or locked.

2.—All manholes at or about the top of each stove shall be provided with platforms accessible by stairways or permanent ladders.

Section D.—Cast Houses:

1.—Casting holes where ladles are loaded under the floors, shall be railed, or where this is not practicable, a grating shall be provided.

2.—Two or more exits from opposite sides or ends of cast houses shall be provided by runways or stairs. Where the cast house floor is elevated permanent or removable railings (not necessarily standard) shall be provided.

3.—All permanent gates in iron and cinder runners shall be operated from a distance.

4.—All men in cast house crews shall wear eye protectors. Men operating or walking about acetylene, electric or oxygen burning apparatus must wear colored eye protectors.

Section E.—Gas Cleaners:

1.—All gas cleaners which may have to be entered while the furnace is in operation shall be provided with one or more valves by which the entering gas can be shut off.

2.—Operating devices for dust catchers shall be arranged to enable the employees to dump them at such a distance and in such a location as to avoid the probability of being burned by hot dust.

Section F.—Stock Houses:

1.—Scale cars and transfer cars shall be equipped with fenders or wheel guards, and warning signals.

Section G.—Pig Casting Machines:

1.—Shields or shelter houses must be provided for protection of the men at the pouring end of pig casting machines.

2.—All men at pig casting machines shall wear eye protectors during the pouring.

Section H.—Relining Precautions:

1.—For relining purpose hooks on brick hoisting lines shall be designed so that in case of fouling, the hook will not be disengaged. The well through which material is hoisted to the working scaffold should be so constructed as to prevent the probability of the bucket fouling, and provided with a toe board around the opening of each platform.

Section I.—Ore Storage Yards:

1.—Any live conductor bar or trolley wires, not a part of a machine, and so situated as to be touched by a person on the ground or permanent passageway, should be protected as far as practicable.

2.—Track fenders or wheel guards shall be installed on all traveling ore handling machinery, except steam shovels, locomotive cranes, and other standard railroad equipment.

Section J.—Docks:

1.—Life preservers and pike poles shall be maintained in conspicuous and easily accessible places on all water front docks.

2.—Snubbing posts shall, as far as practicable, be of a type that will lessen the probability of the lines slipping off.

Bessemer Department of Steel Plants

These rules are intended to cover the fundamental safety requirements for Bessemer converters, hot metal mixers, cupolas, strippers and other equipment pertaining to the manufacture of Bessemer steel.

Section A.—General:

1.—Valves, switches and operating levers that control the movement of machinery covered by this code shall be provided with devices which will permit them to be locked.

2.—Standard platforms provided with permanent stairways or iron ladders shall be installed at all elevated points where employees daily or frequently are required to go. This rule does not apply to railroad structures.

3.—All men engaged in the pouring or handling of molten metal or molten slag shall wear eye protectors.

4.—Pouring platforms and other places where men are endangered from molten metal shall be provided with at least two exits.

Section B.—Hot Metal Mixers:

1.—All mixers shall be equipped with counter balances or an automatic mechanical device which will either return the mixer to an upright position or prevent it from upsetting in case the power is off the tipping mechanism.

2.—All mixers operated by hydraulic power shall be equipped with an emergency valve, so arranged that if the main operating valve fails while the mixer is pouring, the emergency valve can be operated immediately to prevent the mixer from upsetting or to return it to an upright position.

3.—A warning signal shall be installed on each mixer to be sounded when the mixer is about to be poured.

4.—Automatic rail stops shall be placed on either side of the opening of the hydraulic hoists used for conveying iron to mixers, and the opening in the floor caused by the raising of the hoist shall be guarded by automatic gates.

5.—Auxiliary hoists on ladle cranes shall be equipped with a type of hook which can be attached by the craneman to tip the ladle after the ladle has been hoisted to pouring position.

6.—There shall be a signal system between the mixer operator and the operator of the transfer ladle to notify the operator when the pouring is finished and the ladle is ready to be moved.

7.—All cages on hot metal cranes shall be arranged to give protection to the cranemen in case of spilling or dropping a ladle of hot metal. The methods recommended are either to provide escape platforms on the outside of the building, which will be accessible from the crane cage, or to provide an enclosed fireproof cage. Where an auxiliary enclosed fireproof cage is installed for emergency purposes, it should be equipped with an auxiliary control for the bridge travel to allow the craneman to move the crane away from the immediate place of danger.

Section C.—Cupolas:

1.—Cupolas shall be covered at charging floor level where men may be at work in same, to prevent chargers from throwing in material, or material falling from stack on to men. These covers are to be constructed so as to allow ventilation to men working in cupolas.

2.—Provision shall be made to cover openings between cupola shell and charging floor.

3.—Drop chutes shall be enclosed as nearly as practicable. Preferably props shall be pulled by snatch block and cable, rather than by hand. Warning shall be given before bottoms are dropped.

4.—When cupola cinder passes through hole in the floor, this hole shall be guarded by a suitable shield or railing.

Section D.—Ladles:

1.—All ladles shall be bottom heavy, and ladle cars shall be equipped with safety devices to prevent ladle tipping.

2.—Iron transfer ladles shall be provided with a warning signal.

Section E.—Vessels:

1.—A signal shall be provided to give warning whenever a vessel is to be turned up or down.

2.—A signal system operated from the scrap charging floor shall be installed to give warning when the vessel is about to be charged with scrap. Signal shall also be sounded when the charging of scrap is finished.

3.—The hydraulic mechanism operating the vessels shall be equipped with an emergency valve so arranged that if the main operating valve fails while the vessel is pouring, the emergency valve can be operated immediately to control the movement of the vessel.

4.—Vessels shall not be blown into stacks.

Section F.—Handling Molten Metal:

1.—Hydraulic pouring cranes shall be equipped with safety automatic devices that will hold the crane jib and ladle suspended in pouring position if the pressure should fail.

2.—The uncapping stand shall be equipped with a barrier to provide cooling of the ingots before they are uncapped.

3.—Ingot mold cars shall be equipped with coupling devices designed so that it will not be necessary under ordinary conditions for men to stand between the cars to couple.

Section G.—Bottom House:

1.—A mechanical means shall be provided for removing material from dry and wet mixers while they are in motion.

Open Hearth, Crucible and Electric Furnaces

1.—Tapping platforms, charging floors and other elevated points should be guarded by standard rails with the exception of pouring platforms.

2.—The opening in railing at tapping platforms for spouts or runners to be provided with a suitable removable guard to protect same when not in use.

3.—Charging machines must be provided with warning signals.

4.—When tearing out a furnace beneath the floor a tight boarding must be built around the furnace to prevent material from falling on workmen below. This should apply when a furnace is to be completely torn out and the uptakes and division walls removed, otherwise a floor in the uptake is sufficient.

5.—Provision shall be made such that when a furnace is down for repairs the gas can not be accidentally turned into the furnace.

6.—All cages on hot metal cranes shall be arranged to give protection to the cranemen in case of spilling or dropping a ladle of hot metal. The methods recommended are either to provide escape platforms on the outside of the building, which will be accessible from the crane cage, or to provide an enclosed fireproof cage. Where an auxiliary enclosed fireproof cage is installed for emergency purposes, it should be equipped with an auxiliary control for the bridge travel to allow the cranemen to move the crane away from the immediate place of danger.

7.—In new construction, charging buggies shall be equipped with coupling devices designed so that it will not be necessary under ordinary conditions for men to stand between the cars or pans to couple.

8.—Provision shall be made such that when a producer is shut off from a main pipe or when furnace is cut out, gas can not be accidentally turned on again.

9.—In crucible practice a safety cable or chain shall be provided at the edge of pouring platform to prevent men engaged in pouring from falling into ladle.

Blooming, Billet, Plate, Bar and Mechanically Operated Mills

1.—Subways or bridges shall be provided when passageways across tables, conveyors or other mill machinery are required.

2.—All gearing or dangerous shafting on roll tables shall be guarded.

3.—Coupling boxes, spindles and wabblers shall be guarded.

4.—Suitable means shall be provided for reaching the top of housings.

5.—Guards should be placed at the dead end of all roller tables to prevent material over-riding the end of the table.

6.—Scale tunnels shall be arranged so that scale can be removed without subjecting workmen to danger of falling hot scale, or if this is not practicable, men shall not go in pit when mill is in operation.

7.—Wherever practicable means shall be provided to protect men working about the rolls from flying scale and cinder.

8.—Power must be shut off pit covers while soaking pits are being repaired.

9.—The sides of bosh tank for quenching crane dogs shall be not less than 36 in. above the floor level.

10.—Counterweights must be guarded.

11.—Means shall be provided to warn the engineer of overspeeding reversing engines.

12.—It is recommended that straight running mill driving engines of 100 h.p. or over, be provided with a speed limit control and engine stop.

13.—Valve, switches and operating levers that control the movement of machinery covered by this code shall be provided with devices which will permit them to be locked.

14.—It is recommended that all platforms, runways, aisles, doors, stairways or ladders be kept as clean as possible.

Hand Operated Merchant and Rod Mills

1.—Spindles, coupling boxes, pinions and wabblers to be guarded.

2.—Danger from uneven or broken floor plates or gratings to be eliminated as far as possible.

3.—Subways or bridges shall be provided when passageways across hot beds, runways, spindles or tables are required.

4. Adjustable guards to be provided at outside of hot beds and skids to prevent material falling off.

5. Hot and cold saws shall be guarded, and means be taken to reduce the number of flying sparks.

6. On small mills where long bars are being rolled in more than one pass at a time, safety posts to be used where practicable, to protect roll hands from being caught in the loop.

Pipe Mills

Section A.—General:

1. These rules are intended to cover the fundamental safety requirements for lap weld mills, butt weld mills, coupling shop, galvanizing plants and all other equipment pertaining to the manufacture of pipe.

2. Standard platforms, provided with permanent stairways or iron ladders should be installed, where practicable, at all elevated points where employees are daily or frequently required to go. This rule does not apply to railroad structures.

3. All machinery, not otherwise mentioned and covered by this code, is to be safeguarded as specified for rolling mills or in general code.

4. Charging and discharging openings in welding and heating furnaces should be provided with shields to protect men from heat and flames.

5. There should be a signal system between the charging and drawing ends of all bending and welding furnaces.

7. Hot and cold saws shall be guarded, and means be taken to reduce the number of flying sparks.

8. Moving parts of threading and finishing machinery should be guarded as prescribed under general code.

9. A means should be provided to notify operators around the furnace when gas is to be reversed.

Section B.—Gas Producers:

1. All openings level with the ground, used for burning out gas flues, should be protected by railings or gratings when flues are being burned out.

2. When men are engaged in repairing gas producers or gas flues, when other producers in the same battery are in operation, suitable gates or valves shall be provided, by which all gas can be shut off.

Section C.—Lap Weld Mills:

1. Solid welding balls should not be used, as holes for the passage of gas should be provided.

2. Forced ventilation should be provided for the men working in intense heat.

3. Space between ends of troughs, conveyors, or tables and roll stands should be barred to prevent passage.

Section D.—Butt Weld Mills:

1. Movable draw benches and chains should be so constructed or guarded as to protect men's feet.

2. Stops or guards should be provided at the delivery end of cross roll troughs.

Section E.—Galvanizing Plants:

1. Where practicable, all tanks shall be protected.

2. Special attention shall be given to the ventilation of galvanizing plants to remove as much of the fumes and steam as possible.

3. Galvanizing kettles shall be railed or shielded.

Section F.—Coupling Shop:

1. Shields should be provided at welding hammers and rolls to reduce the number of flying sparks.

2. All coupling shop machinery should have the moving parts guarded as prescribed under General Code.

Section G.—Job Shop:

1. All machinery used for special work in job shops should have the moving parts guarded as prescribed in the general code.

Wire Mills

These rules are intended to cover the fundamental safety requirements for the wire drawing, rolling and fabricating departments of wire mills.

1. Standard platforms, provided with permanent stairways or iron ladders, should be installed, where practicable, at all elevated points where employees daily or frequently are required to go.

2. It is recommended that all platforms, runways, aisles, doors, stairways, ladders, fire escapes, or fire apparatus be kept as clean as possible.

3. Where practicable, all tanks or tubs should be protected.

4. Wire drawing, rolling and fabricating machines shall be equipped with means, conveniently located for quickly shutting down the machinery in case of emergency.

5. Screens or railings should be provided to protect open pot annealing furnace while being repaired or not in use.

6. Passageways under hot wires from annealing furnaces shall be protected.

Sheet and Tin Mills, Tinning and Galvanizing

1. Shearmen, openers, loaders and machine feeders should be required to wear gloves or hand leathers, and proper protection to the forearm.

2. It is recommended that all tools, furnished either by the employer or the workmen should be kept in a condition of good repair and it is the workmen's duty to report all unsafe tools or equipment to his employer.

3. It is recommended employees should take proper precaution to prevent cold or wet objects coming in contact with molten metal.

4. Workmen shall wear eye protectors when grinding, chipping and atteading galvanizing pots and tinning pots, unless other protection is provided.

5. Standard railings shall be provided around flywheels and drives. Cross-overs or bridges with hand rails should be provided when passage from one side of the mill to the other is necessary.

6. Wabblers on the end of the roll train shall be guarded, also the entering side of mill couplings when more than one roll is driven.

7. Shields shall be placed over furnaces doors to protect workmen from heat.

Puddling Mills, Busheling or Scrap Furnaces

It is recommended that the following shop rules be adopted:

1. When furnaces are to be fired, the dampers must always be pulled up before the blast is turned on.

2. Before charging a furnace, the cinder on the bottom of the furnace shall be permitted to cool off until it is non-fluid.

3. All obstructions must be cleared off the standing before charging a furnace.

4. When tools are taken from the bosh, they must be dried off before placing in hot metal.

5. When throwing scale into the heats of hot metal, care must be taken to see that the damper of the furnace is pulled up its full height.

6. After a heat of iron has been drawn from the furnace, the damper must be pulled up or adjusted to full draft before cooling off or fixing the furnace.

7. When throwing water into a furnace to cool off the cinder, it should be used in small quantities and extreme care taken to see that there is no bosh cinder or other solid bodies in it. At no time is any wet or damp material to be thrown into a furnace when there is melted cinder on the bottom of the furnace, when the damper is down, or the draft is shut off.

8. The throwing of water on balls of iron when taking out of furnaces to the hammer or squeezer is strictly forbidden.

9. No water shall be allowed to accumulate on the standings of furnaces, or along the mill races that the hot iron is run over to the squeezer or hammer.

10. In putting iron in the squeezer, great care must be exercised not to put the basket or tongs between the drum of the squeezer and the ball. In the event that tongs or baskets are caught the workmen must let go of same at once.

11. Furnaces are not to be fired without slacking the blast sufficiently to keep flames from the fire chamber burning the men working about the furnace.

12. Hot taps must not be placed near water.

13. When dumping tap buggies, care must be exercised to not allow cinder to come into contact with damp or wet ground.

14. Water must not be thrown on hot taps.

General

1. All bloom boys and roll hands must wear goggles or copper wire face masks.

2. All dampers and doors on furnaces must be properly balanced and balance weight must be adjusted by the workmen and securely fastened each time.

3. Where switches are in use on a telepherage system sufficient light must be provided by which to change switch.

4. When ash pits are two or more feet deep, safe and substantial means of access to and egress from pits shall be provided.

5. Muck mills shall be protected in accordance with rules pertaining to hand-operated rolling mills.

BLACKING AND WAXING SMALL CASTINGS

FOR a good many purposes it is neither necessary nor desirable to paint iron castings. In such cases blacking and waxing usually fills the bill, and being very simple can be carried out anywhere. After being cleaned off and dressed up, the castings are blacked and polished with some good stove polish, or fine black lead wetted down with turpentine, and after being polished are made hot and thinly coated with beeswax or other tough form of wax. When cold they are again brushed up. As a general thing they will then resist rust in all ordinary indoor positions. The wax appears to attach itself very firmly to the hot metal and prevent air and moisture reaching the surface, while a very small quantity need be used. Hard waxes such as carnauba wax, and paraffin, do not seem to be so effective as beeswax, and can therefore be left alone in regard to this kind of work.

CASTING METALS IN IRON MOULDS

By W. J. May.

UNDER suitable conditions and with certain forms of castings, all metals can be cast in iron moulds of some amount of thickness, but, owing to the cost of the moulds, this can only be done economically where very large numbers of precisely similar castings have to be made. Up to the present time no very great progress has, consequently, been made, "die-casting," as it is called, having been restricted to the casting of soft metals by a few firms who have had courage enough to break away from the old-fashioned methods of doing foundry work. In the result, however, they appear to have had a fair amount of success. That there is a demand for this class of work is becoming apparent.

Of course, casting in metal moulds is not a new process, as type has been always cast in such moulds, and tube and strip ingot for drawing and rolling is cast in iron moulds. It is simply the extension of a somewhat old process to a wider field of operation that has to be arranged for amongst mechanics not trained for the work. In the near future, however, it is practically certain that there will be greater standardization of work and in such things as permit of it, increased cheapness of production will be sought, even where this increases the wages of the individual worker. Really, it does not matter what a man earns so long as he reduces the cost of the articles he produces. Permanent mould casting and machine forging in dies will have, very largely, to take the place of handwork, and the sooner this is recognized the better for all concerned, as both mean considerable reductions in the cost of production.

Metal Moulds and Sand Moulds

In dealing with metal moulds a great many people seem to think that they have the same conditions as with sand or loam moulds; but in this they are working on wrong lines. In sand or loam moulds, gases and air pass into and through the mould itself, and in this way the exact state of the metal poured is not so stringently important, because up to a certain point there is a fairly free escape for all gaseous matters formed or contained in the moulds and metal. With the metal mould there is no escape for any gas unless vents are provided. In the case of dirty metals likely to throw off gases this is a serious matter, because if the escape vents are insufficient or wrongly placed the gases become occluded and porous castings result. It, therefore, becomes necessary to design moulds to prevent such troubles.

Every case must be dealt with according to local conditions, however, and no strictly hard-and-fast lines can be laid down. So far as the metals and alloys are concerned, they must be clean and free from oxides or other gas-forming matters, and they must be fluid. As a rule, freshly melted metal is necessary, and in addition it should be melted quickly. In many cases some deoxidant flux will be required, and this must be an effective one.

On the economic side of the question, permanent moulds have to be kept busily at work during the time they are in use, and to get good results it is necessary that a number of moulds and a sufficiency of crucibles to keep them going should be employed. It is of no use to pour on chance occasions for one or two castings, as this is certain to prove a failure, and generally it is useless to work for less than full days, and then only with a group of men and boys selected for the job. To obtain economy in working, a regular routine must be followed for fairly long periods. As a rule, iron moulds do not work well at first, as some change takes place in the machined surfaces for some time. For this reason part of the first lot of castings are practically certain to be useless, although eventually, with careful working, very few wasters are produced.—Practical Engineer.

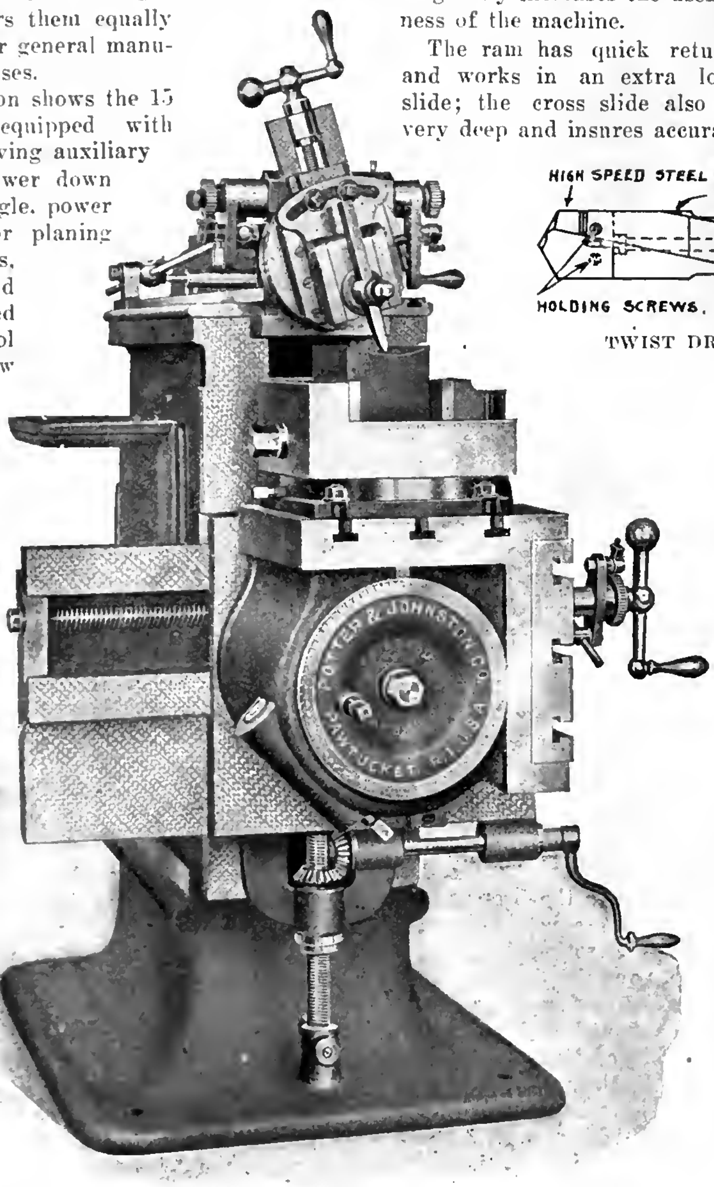
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

UNIVERSAL SHAPING MACHINE

SIMPLICITY of design, convenience of operation, and extreme care in manufacture characterize the Universal Shaping Machines which are built by Potter & Johnston Machine Co., Pawtucket, R.I. These machines are made in 15 in. stroke and 24 in. stroke sizes, and, while primarily intended for the finest grades of die work and tool making, the substantial nature of their construction renders them equally well adapted for general manufacturing purposes.

The illustration shows the 15 in. machine equipped with swivel table, having auxiliary tilting side, power down feed on any angle, power rotary feed for planing internal curves, automatic feed stop, graduated collars on tool head feed screw and table feed screw, and swivel vise, with graduated base.



15-IN. UNIVERSAL SHAPING MACHINE.

The swivel table has tee slots on two of its sides, and revolves through an arc of 90 degrees to zero, and is accurately graduated in front so that pieces may be machined to any precise angle without tentative setting. The table is revolved by worm gearing, and can be fitted with an auxiliary tilting side for obtaining compound angles, a valuable feature in tool room work.

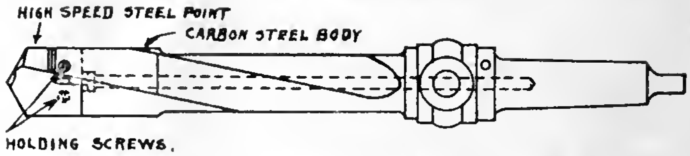
The down feed can be varied while the machine is in motion and is thrown out by a positive stop at any predetermined point. Power rotary feed to the head enables internal curves to be accurately formed and greatly increases the usefulness of the machine.

The ram has quick return, and works in an extra long slide; the cross slide also is very deep and insures accurate planing to the limit of the stroke. Hardened and ground steel faces are fitted to the vise jaws, one of which swivels for gripping irregular work, the construction of the jaws being such that the work is drawn down when gripped.

All belt-driven machines have a two-speed countershaft giving six changes of speed with a three-step cone, while motor-driven machines have a special base extension for electric motor. The net weights of the two sizes of machine are 2,500 lbs. and 4,400 lbs. respectively.

TWIST DRILL WITH RENEWABLE POINTS

THE extent to which the cost of high-speed steel is influencing the construction of small tools is illustrated by the use of this material for the cutting point only in large drills used in drilling high-explosive shell billets.



TWIST DRILL WITH RENEWABLE POINTS.

The accompanying illustration shows a type of twist drill constructed in this manner by Leadbeater & Scott, Sheffield, in which a good grade of carbon tool steel is used for the body and a cutting point of high-speed steel is detachably mounted on the end. A small pilot boss centralizes the drill point on the end of the body, the drive being taken by a tongue on the back of the point, fitting in a groove milled across the end of the body. The point is held in position by two hardened screws, which are free of any driving stresses.

The sketch shows a drill with central lubricating channel opening to each lip, and a body diameter reduced so as to minimize binding stresses in the hole and give free exit for chips.

ONE TON DELIVERY TRUCK

BY the conversion of a Ford car into a light and serviceable one-ton truck, the Fairbanks-Morse "Redden Truck-Maker," offers an ideal vehicle for quick and inexpensive delivery. This attachment is so constructed that it is adaptable to any type of Ford car, and can be attached in a few hours without any machine work or alteration of car construction.

The attachment makes use of the existing rear axle as a jack-shaft and adds a new axle and wheels. A lower gear ratio obtained by means of the driving sprockets enables the Ford motor to handle the load with as much ease as it does its passenger load, the increased gear ratio reducing the speed to a safe

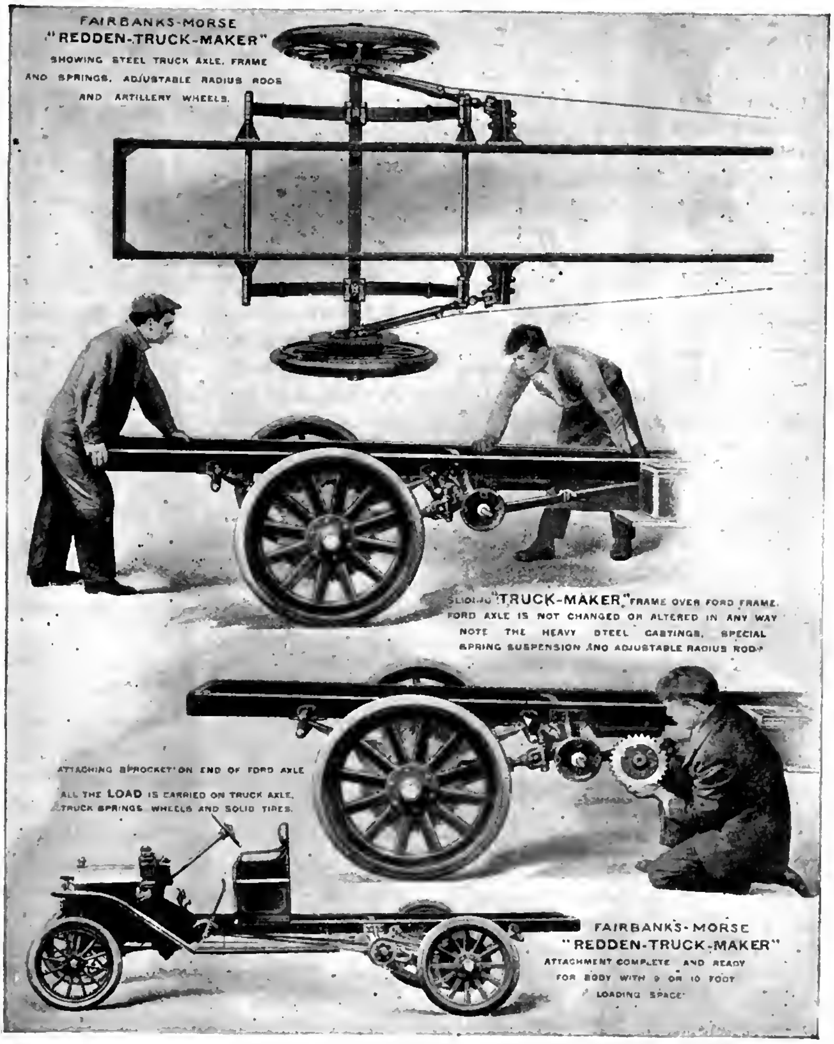
and conservative rate of 14 miles per hour.

The frame of the attachment is made of 4-inch channel-rolled steel, with a length (back of the driver's seat) of 8 feet 8 inches. The rear axle of the truck is secured to the frame by means of 40 inch. semi-elliptical springs. The rear axle thrust is taken by adjustable radius rods, the rear axle being so located that the load comes entirely upon the rear wheels and axle, thus relieving the forward portion of the car of any additional strain. The wheels are of heavy artillery type, S. A. E. standard 34 x 3, and supported on heavy duty roller bearings. The drive is transmitted through heavy roller type chains from a 20-tooth sprocket on the car rear axle to one of 40 teeth secured to the truck axle.

"REDDEN TRUCK MAKER"

Special cast steel brackets, bolted to the auxiliary, or truck frame support the car axle. The rear wheels are equipped with 12 in. expanding emergency brakes, fitted with fibre lined shoes.

When attached to a Ford chassis the wheel base is 132 inches with a tread of 64 inches, furnishing a loading space of from 45 to 50 square feet. The attachment has an approximate weight of 900 pounds, and through its simple construction combines strength and economy; in addition to ease of operation, minimum fuel consumption and repair expenditure.



SINGLE PURPOSE BAND TURNING MACHINE

A BAND-TURNING machine of highly specialized design is shown in the accompanying photographs, Figs. 1 and 2, which is built to handle shells from 3 in. to 6 in. in dia. The high degree of accuracy demanded in this work is insured by the integral construction of the machine, while capacity is likewise insured by the simplicity and ease of operation.

The work is held in a push collet chuck contained in the nose of the spindle, the main bearing being made sufficiently large to accommodate it as shown in Fig. 3. The base of the shell is supported by a conical cup bearing mounted on a hinged bracket which is swung out of the way when changing the work. This bracket is adjustable along the bed so as to allow a particular size of shell to be accurately located, the action of the push collet chuck being to press the shell outwards into the cup rest which thus automatically centres the base end and also acts as a locating stop for the shell length wise so that the band is in the correct position relative to the cutting tools.

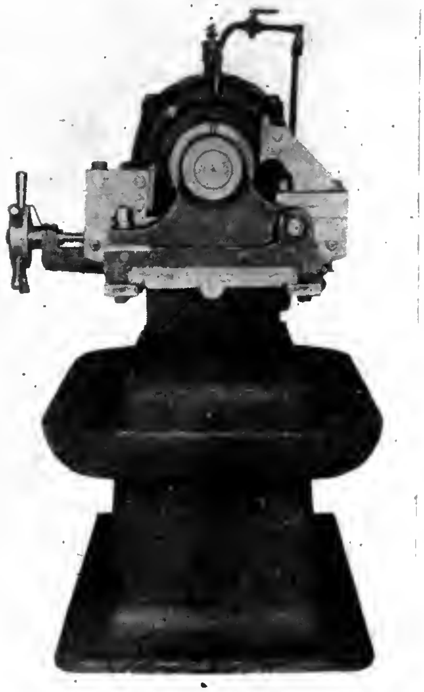


FIG. 1. END VIEW OF BAND TURNING MACHINE.

Two cutting tools are employed, each of which finishes half of the band pro-

file. They are fed in simultaneously, a large diameter micrometer dial being provided on the hub of the hand wheel. Ample power is obtained through a 15 in. by 6¼ in. pulley mounted on the spindle, while lubricating and coolant requirements are fully provided for.

FIG. 2. 6-IN. BAND TURNING MACHINE.

The machine illustrated is for handling 6 in. shells and has main spindle bearings 8½ in. x 7¼ in. front, and 5¼ in. x 4 in. rear, the total weight being 2,700 lbs. It is the product of the Roelofson Machine & Tool Co., Toronto.

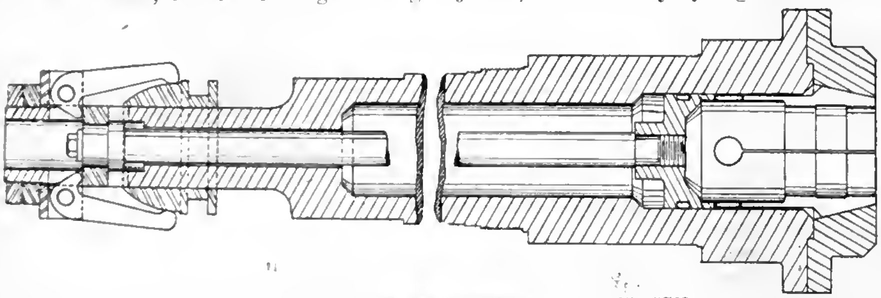

FIG. 3. DETAILS OF PUSH COLLET CHUCK.

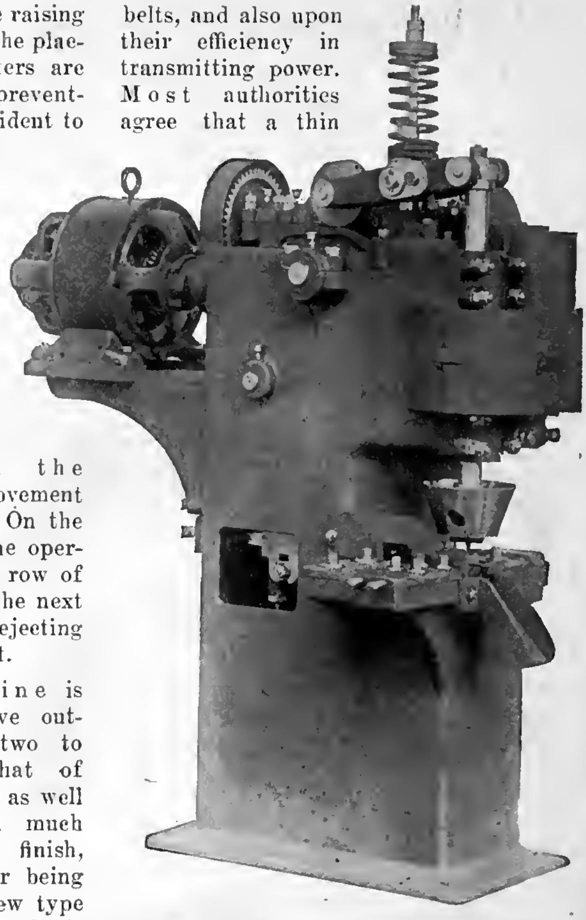
SEMI-AUTOMATIC BURRING MACHINE

THE accompanying illustration shows a semi-automatic burring machine for removing the rough edges or burrs from all standard sizes of square and hexagon hot pressed nuts, manufactured by the National Machine Co. of Tiffin, Ohio. It is operated by a direct-connected, adjustable speed, direct current Westinghouse motor, having a two-to-one speed ratio with a maximum speed of 1,160 r.p.m. With this machine it is only necessary for the operator to place the nuts in the slot and push them forward. The raising and lowering of the spindle and the placing of the nuts under the cutters are handled automatically, thereby preventing all possibility of accident incident to feeding nuts otherwise under a rapidly revolving cutter. An injector automatically moves the nut to be burred under the cutting head and the operation is performed on the downward movement of the head. On the latter rising, the operator moves the row of nuts forward, the next incoming nut ejecting the finished nut.



SEMI-AUTOMATIC BURRING MACHINE.

This machine is claimed to give outputs of from two to four times that of hand machines, as well as securing a much more uniform finish, all of the burr being removed. A new type of burring head is used, which effectually cuts off all the fin when the cutters are gradually lowered by a cam feed. Safety reliefs are provided upon the vertical movement of the burring spindle and on the nut injector, and a safety spring takes care of any variation in nut thicknesses. The machine is readily changed over from one size of nut to another.

Wear and deterioration of belts may be caused in various ways. Frictional heat injures leather belts by burning the fibres, and this action is particularly rapid when the belts slip excessively. Belts hanging loose on revolving shafts, and even belts in operation, may be rapidly worn away by abrasion when the air of the shop contains gritty dust. Temperature, moisture, the tightness or looseness of the belts, and the general condition of the lacings and fastenings, all have an influence upon the life of the belts, and also upon their efficiency in transmitting power. Most authorities agree that a thin belt will hug a pulley better than a thick one, which is equivalent to arguing that belts should be used as thin as the service will permit.

MACHINABLE ACID-PROOF IRON

A CAST iron, claimed to be easily machinable and acid-proof and known as Corrosiron, is made by the Pacific Foundry Co., San Francisco. It is high in silicon and can be cast in difficult shapes. Many pieces have been made with bars of iron or steel cast within the metal, giving added strength. Because the alloy is inclined to be brittle it must be handled carefully. Its strength is reported to be half that of cast iron, a bar $1 \times 2 \times 24$ in. giving a transverse strength of 1,200 lb., with a deflection of about 0.14 to 0.18 in. The fracture is described as similar to that of ice, with long, flat crystals, but not granular. The shrinkage is 3-16 in. to the foot, about that of brass. Flat surfaces are avoided in designing, corners are rounded and the sections of metal are kept as even as possible. The greatest loss in some corrosion tests was 0.58 per cent. in 17 days' immersion in concentrated hydrochloric acid, while the smallest was 0.0015 per cent. in 7 days' immersion in various strengths of nitric acid.

MACHINERY EXPORTS TO RUSSIA

TOWARDS the end of November, last year, the British Government took more or less drastic action relative to the importation of machinery of various kinds, and recently the Russian Government has become active along similar lines. The avowed idea in both cases is to minimize if not to wholly abolish all tendency to speculation in machine tool and kindred equipment imported to meet the needs of manufacturers. Before machinery can now be cleared for Russia, or at least before it will be allowed to land, full details of what constitutes the shipment must be placed on record with the Russian Government representatives, 44 Whitehall Street, New York City. Among other things, the name of the ultimate consignee must be given, and a deposit of fifty dollars be made to meet cost of cablegrams, etc., which may be necessary for the New York executive to transmit to and from Russia regarding the shipment under consideration.

Additional to the foregoing, and with a view to utilizing to the fullest possible extent the resources of the port of Archangel and other White Sea ports for the successful prosecution of the war, the Russian Government have decided to prohibit, except under special permission, the entry into those ports of all cargoes not destined for purposes of national defence. Manufacturers, merchants and others are accordingly invited to transmit to the secretary of the Commission Internationale de Ravitaillement, India House, Kingsway, London, W.C., particulars of all goods (including goods the export of which is not prohibited) which they desire to ship to Archangel during the coming season, giving same in the following order:—Nature of goods; quantity; approximate weight and measurements; names of consignors and consignees; approximate value; and month or months of shipment.

In the case of prohibited goods for the export of which sanction has been obtained, the following particulars should be given: 1—Number of the relative Commission Internationale de Ravitaillement permit, or, 2—Number of the War Trade Department license. It must be clearly understood that the supply of the above-mentioned particulars is in no sense a guarantee that shipment will be permitted. All envelopes should be marked "Archangel."

IS A STEEL MERGER IMMINENT?

RUMOR has it that a merger of the Dominion Steel Corporation, Nova Scotia Steel & Coal Co., Steel Co. of Canada, and Algoma Steel Corporation is on the tapis; and as is to be expected at this stage of the game—even granting some foundation for the scheme, nobody knows anything about it. However, in every instance, those likely to be directly in touch with such a project are disposed to be guardedly indifferent, if we might so put it, when approached.

As a result of munitions contracts filled and in process, all our big steel industries are to-day on easy street financially, and as regards plant equipment and expert administration are individually competent to maintain their position in a world competitive sense in the coming time. We are not therefore inclined to put much credence in the merger reports, although we would not be surprised to find Dominion Steel and "Scotia" develop the already initiated tendency to draw closer in the immediate future. The establishment of a shipbuilding plant by the latter, and the possession by the former of a plate mill of substantial capacity, although awaiting installation, lend color to the suggestion put forth. The new management of Dominion Steel has all the ear-marks of progressiveness and in the nature of things a rapprochment with "Scotia" has been therefore made possible. We expect, as above stated, to see a further development of this feature, and estimate that while the merger as per rumor may ultimately be realized, it will for some considerable time be kept in abeyance.

On the question of law, the merger consummation would undoubtedly usher in a hey-day period for the legal profession, as no matter how explicit it may be endeavored to construct and define a statute, and what is involved in the proposed merger would easily be no exception, a long and bitter fight for and against is sure to be staged. It is estimated that with the four concerns named, some 95 per cent. of our steel-making enterprise would be embraced, and it goes without saying that "a combination in restraint of trade," which is illegal in Canada, would then appear to exist. Even the United States Steel Corporation, which by the way won out in its fight against dissolution, does not hold within its scope more than 40 per cent. of American steel-making enterprise, hence, so far as the Canadian steel merger is concerned, the odds are much against it on account of its almost 100 per cent. comprehensiveness. The following clause of our criminal code is, we understand, applicable, or would be taken as being so:

"Every one is guilty of an indictable offence and liable to a penalty not exceeding four thousand dollars and not less than two hundred dollars, or to two years' imprisonment, or, if a corporation, is liable to a penalty not exceeding ten thousand dollars and not less than one thousand dollars, who conspires, combines, agrees or arranges with any other person, or with any railway, steamship, steamboat or transportation company—

(a) To unduly limit the facilities for transporting, producing, manufacturing, supplying, storing or dealing in any article or commodity which may be a subject of trade or commerce; or

(b) To restrain or injure trade or commerce in relation to any such article or commodity; or,

(c) To unduly prevent, limit or lessen the manufacture or production of any such article or commodity, or to unreasonably enhance the price thereof; or

(d) To unduly prevent or lessen competition in the production, manufacture, purchase, barter, sale, transportation or supply of any such article or commodity, or in the price of insurance upon person or property."

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, June 12, 1916.—The outlook for future trade conditions continues bright. Gradual increase is shown in the volume of business, both from the domestic and munition standpoint. The prospect of lower ocean freight rates is expected to encourage increased export business, in view of the contemplated move on the part of the British Admiralty of releasing a number of merchant vessels.

Pig Iron

The general situation is similar to that of the past few months, but a slight undertone of weakness is developing, and prices are expected to become easier. However, the activity in the producing field is as great as ever, with no easing up in requirements of the steel makers.

Steel

While the market is beginning to show a quieter tone, due largely to the general easing off during the summer months, the situation from a manufacturing standpoint shows little or no change. The scarcity of steel is still very noticeable, but premiums for early delivery are less frequent. Conditions in the plate trade are relatively unchanged, with the demand still very heavy. New demand for light black and galvanized sheets is quiet; but the demand for blue annealed and special sheets is still very great. The general market has been quiet, with very few price changes. Chicago price on iron bars is now 2.45c, being an advance of 1-10c per pound. Quotations on tin plate have advanced ½c, and are now 6c. Galvanized sheets are lower by 1-10c per pound.

Metals

Developments during the week have been very few; spelter being the only metal to show activity on an otherwise quiet market. Following a brief period of heavy buying early in the week, which showed signs of increasing in proportion, the market suddenly quieted down again to its previous conditions. Copper is quiet, and buying is light. Special developments are looked for in tin, owing to a number of conditions related to the present situation. Lead is dull and weakening. Antimony continues to show weakness with declining prices.

Copper.—The present market is quiet and transactions are comparatively light. The fact that many consumers are oversupplied has had the effect of bringing considerable resale metal upon the market. It is thought, however, that much of this copper will be withheld should the market become active. London reports a firm market under a comparatively light trade. Standard spot advanced £3 10s from £120; futures advanced £1 10s. from £118; and electro spot, with £2 advance, is quoted at £142. New York reports a quiet market, with prices weakening. Lake and electrolytic are ¼c lower, both being quoted at 28¼c per pound. Castings show a decline of ⅛c, present price being 26c nominal. No change is noted in local conditions.

Tin.—Owing to the recent dullness, quotations on future positions are relatively low, and dealers and producers await developments. Owing to the high prices prevailing in Great Britain, London reports a very quiet market, with quotations strong and advancing. The New York situation is still weak, and consumers show little interest in current developments. Quotations are easier, a decline of ½c placing the nominal figure at 44¾c per pound. Dealers here report unchanged conditions, with prices firm at 48c per pound.

Spelter.—Following the recent strength shown in spelter the market has again become quiet, quotations declining. It was generally anticipated that the firmer tone would stimulate buying, but no response occurred. Galvanizers are taking increased interest in the buying of spelter; while on the other hand, the brass mills are doing very little buying. Present London prices are £1 higher than those of a week ago. New York spelter is slightly stronger. An advance of ⅝c on the week placed present prices on a nominal basis of 14.05c per pound. In view of the continued dullness prevailing in spelter for some time previous to the recent activity, local dealers show a

further decline in their quotations. Current prices here are 17c per pound.

Lead.—The Trust price, after a decline of ½c, is quoted at 7c, with outside prices 6.95c, being a decline of about ⅜c per pound. Following the weakness on foreign markets, local dealers have declined ¼c on a very quiet market; present prices being 9c per pound.

Antimony.—In the face of an almost negative demand, the situation as regards antimony is very dull. New York quotations show a further decline of 2½c on foreign and American metal, the current price on both being nominal at 22½c per pound. Local dealers report a very quiet situation, with prices declining. This week's quotation of 33c represents a decline of 3c per pound.

Aluminum.—Conditions are unchanged, with prices somewhat stronger in the States. Dealers here, however, are declining on a steady market, quoting 65c, a drop of 3c per pound.

Machine Tools and Supplies

In spite of the fact that very few large orders are being placed for machine tool equipment, the trade is busy supplying requirements of manufacturers, both munition and domestic. Many large shell makers are still adding equipment, some of which are tools received on long placed orders. Delays in delivery are not so pronounced as a few months ago. Domestic requirements continue to be satisfactory. While the demand for supplies continues heavy, the situation is becoming less acute, owing to the easier prices prevailing. Quotations on finished material are gradually declining, and the cost of supplies is relatively effected.

Scrap

Little activity is shown in the scrap situation. Dealers report a quiet market, with prices declining. Consumers of heavy melting steel scrap are apparently well supplied for immediate needs. The general situation is comparatively quiet and prices are becoming easier. Machine shop turnings and also wrought iron scrap are plentiful. Changes this week all show a decline: machine compositions quoted at 15¾c, a decline of ¼c: under a similar decline new brass turnings are quoted at 15c per pound. Quotation of 5¾c on heavy and tea lead show a falling off of ¼c. Scrap zinc is 1c easier, being quoted at 11c.

Toronto, Ont., June 12.—The outstanding feature in the industrial situation is the indication that prices have advanced about as far as they are expected to go. This means that raw material will most probably not increase in cost to any appreciable extent. The scarcity of labour and shortage of raw materials may, however, affect the situation to some extent, causing a shortage of some lines and probably higher prices. The ocean freight situation is improving, rates having already declined owing to more tonnage being released. The situation in the steel trade is unchanged and the greatest activity prevails. The market is very firm and prices unchanged. The ingot metal markets continue weak and declines in prices of tin, lead, spelter and antimony have to be noted.

The decision arrived at by the Imperial Munitions Board to retain the original type of 8 in, and 9.2 in., shells and not adopt a new design will permit the manufacturers to proceed without delay with the preparation of their plants. The proposed shell forging was to have a closed base and open parallel mouth whereas the adopted design calls for a forging with a conical nose and open base. Large swing lathes will be required for making these shells and considerable equipment orders are looked for from forging plants and machine shops.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel

The market continues steady and firm with prices stationary. The upward movement appears to have about reached the top and any material advances are unlikely except in some steel products which are subject to special conditions. While prices may not advance much further there is little possibility of a decline and the present high level will no doubt obtain during the remainder of this year at least. The situation in the steel trade has not changed, the mills having all the business that they can take care of; orders on the books running well into 1917. Production, however, has increased considerably, and in addition, the new demand is not as heavy as it was, relative to the capacity of the mills to meet it. The latter are thus in a better position to take care of the increased demand than they were earlier in the year. While there are no price changes to note this week, quotations are very firm. Wrought iron pipe for instance is very firm and may advance on account of the scarcity of skelp, several makers of this material being sold up for the remainder of the year. Makers of boiler tubes are in the same position but as new buying is light a change in prices may not be made in the meantime. There is a big demand for wire rods and prices are very firm.

The decline in the price of spelter is improving the situation in galvanized sheets, but as it is no longer the sole factor in causing the present high price of sheets, a material decline in this material is not anticipated. Black sheets, acid and labour are all high, which will tend to keep up the price of galvanized sheets. Inquiry for black sheets continues lighter than it was several weeks ago. New orders are, however, generally in excess of the mill capacity. Sheet bar supplies are still below full requirements.

In the United States new buying is lighter but shipments by the mills against contracts are heavy and the demand on the mills by customers is still urgent. The steel market, however, is quiet, the usual summer dullness already being felt. Prices are firm and unchanged. The unfilled orders of the U. S. Steel Corporation about 9,937,798 tons, an increase of 108,247 tons over the previous month.

Scrap

The market is dull and prices have a weak tendency. Brass scrap, lead and zinc have declined but prices of other metals are practically unchanged from last week.

Machine Tools

Considerably greater activity is looked for in the machine tool business now that a decision has been arrived at with regard to the design of the 8 in. and 9.2 in. high explosive shells. Manufacturers who have been awarded contracts for these shells will now be able to go ahead with the preparation of their plants. A number of large swing lathes will be required and it is expected that orders will be placed shortly for all necessary equipment. As the design of the shells in the new contracts will be the same as in the original orders there will be less delay than would otherwise have been the case. Deliveries continue slow especially on standard tools.

Supplies

Business continues brisk but delay in obtaining supplies from manufacturers is causing dealers some inconvenience. This applies more particularly to iron and steel goods and is due to the shortage of raw materials. Linseed oil has again declined due to light demand, while turpentine is also lower for the same reason. French medal glue has advanced 2c, the market being very unsettled and quotations nominal when supplies are available.

Metals

A general weakness previous in the metal markets, copper being only metal to maintain any degree of strength. Tin, lead, spelter and antimony have all declined. The demand for practically all metals which enter into the manufacture of munitions has been steadily declining during the past two or three weeks. Prices have all been affected with the exception of copper which is unchanged. The situation in metals is engaging attention. Whether conditions are shaping for a general revival in both demand and price or for further depression is subject of considerable interest.

Copper.—The market is quiet and dull, with prices unchanged. New buying has been small and has been confined mostly to re-sales of metal by second hands. As the larger producers have sold up all of their production for some time ahead no weakness is likely to develop. Local quotations are unchanged and nominal at 30½c per pound.

Tin.—The market is dull and lower due to light demand. Consumers are showing little interest and are waiting until the market shows definite signs of turning. Indications point to a re-action towards higher prices. Tin has declined 1c and quotations are nominal at 50c per pound.

Spelter.—The market is quiet and lower following a decline in London. Galvanizers are showing more interest in the market but very little spelter has been bought recently by the brass mills. Spelter has declined 1c and is quoted at 18c per pound.

Lead.—The market is dull and weak. The "Trust" price has declined to 7c New York, and on the outside market is lower for both spot and futures. Over production has caused the decline. Lead has declined ¼c and is now quoted at 9c per pound.

Antimony. — Prices have again declined and there is no demand at present and prices are purely nominal. Smaller consumption combined with increased competition has been the cause of the decline. Quotations are nominal at 35c per pound .

Aluminum. — The market is firmer but quotaions are unchanged at 64c per pound.

ARMSTRONG-WHITWORTH PLANT EXTENSION

THE Armstrong Whitworth of Canada, of which M. J. Butler, C.M.G., is managing director, and Lawrence Russell, secretary-treasurer and sales agent, have given out contracts for the doubling of their already extensive plant at Longueuil by the expenditure of three quarters of a million dollars. Mr. Butler states the present floor space of 50,000 square feet will have been increased to 100,000 square feet on completion of the contracts just given and expects that if all goes well the new unit will be roofed in by the month of September and the machinery installed a few months later.

At present all the available space is being utilized and while 250 men are now employed in the different departments, the number will in all probability be increased to 500 when the new buildings are completed and the machinery in running order. Besides the coming additions a new storehouse and office building will be erected.

The new addition will comprise a plant for the manufacture of steel tires for locomotives and passenger rolling stock as well as for the rolling of steel wheels and the manufacture of forged axles. They will likewise add a rolling mill and provide for the making of special rounds and shapes from electric smelted steel. This is the first time we understand that the manufacture of steel wheels has been undertaken in Canada, and it is being done to meet the now heavy demand for such wheels which are necessary to carry cars of seventy-five tons weight.

The contract for the steel work has been given to the Dominion Bridge Co., and the remaining work to The John Quinlan Co. In fact most of the new extension is to be done by Canadian firms, although a part of the machinery will be manufactured by the Morgan Engineering Co., of Alliance, Ohio, who are experts in all matters pertaining to rolling mills.

Mr. Butler says that the market for the company's goods has gradually expanded since the opening of the plant, hence the decision to spend an additional three-quarters of million dollars on a new addition.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

YARROW'S, ESQUIMALT, B.C.

RECENT work carried out at Yarrow's shipbuilding yard at Esquimalt, B.C., is indicative of considerable activity. In addition to a great deal of foundry work carried out for the Victoria Chemical Co. and others, the following list covers vessel overhauls and repairs, etc:

Steel sternwheeler under construction.

Sir John Jackson's hopper SS. Hercules No. 7, docked on slipway, underwater portion of hull cleaned and painted, and some damaged shell plating repaired.

C. P. R. SS. Princess Charlotte docked in the Dominion Government drydock; underwater portion of hull cleaned and painted.

Salvage steamer Alaskan docked on the slipway; underwater portion of hull cleaned and painted, and some hull and engine repairs executed.

Collier SS. South Pacific docked in the Dominion Government drydock; underwater portion of hull cleaned and painted.

C. P. R. SS. Princess Alice docked on slipway; underwater portion of hull cleaned and painted, together with small hull repairs.

Dredging fleet vessels tug Point Ellice, dredge Ajax and dredge Victoria docked on slipway for annual overhaul and repairs.

C. G. S. Newington locked on slipway; underwater portion of hull cleaned and painted.

Cable ship Restorer; the installation of oil fuel burning system completed.

Union Steamship vessels SS. Camosun; extensive bottom damage repairs carried out, together with engine overhaul.

LACHINE CANAL MAY TRAFFIC

BECAUSE shortage of available tonnage has greatly curtailed the amount of coal being brought up to Montreal and St. Lawrence ports by ocean and coasting steamers from the Maritime Provinces, the May returns for the Lachine Canal show an increase of 100,890 tons of coal in the amount brought down from American ports as compared with the coal brought down for the same month in 1915.

This coal has been an absolute necessity for many firms who are now running their factories day and night, but it has also had the effect of limiting to a certain extent the lake vessel tonnage available for bringing wheat down to Montreal from the Upper Lakes. This tonnage had already suffered a notable diminution because of the vessels suitable for

ocean navigation which had been tempted to abandon the Lakes for the more profitable business at sea.

So far as the Canadian West was concerned, the situation was saved last year by American vessels, which rushed all the wheat they could to American lake ports, whence it was taken by rail to American Atlantic ports to swell their returns as to wheat exports. The Canadian railroads have also done yeoman service in sending long caravans of trains eastward laden with grain, and these trains are estimated to have brought more grain to the elevators of the harbor commissioners than have the boats, even though in normal times the greater part of the grain passes first through the Lachine Canal.

Grain Carried

The amount of wheat which came through the Lachine Canal in May this year is less than a quarter of what it was for the same month in 1915. The figures are as follows: May, 1915, 8,632,-508 bushels; May, 1916, 1,865,468 bushels; a decrease of 6,767,040 bushels.

The total amount of grain which came through the canal in May for 1915 and 1916 respectively was 11,480,252 bushels and 4,068,227 bushels, an advantage for 1915 of 7,412,025 bushels of grain. The only increases shown were in the cases of barley, of which 487,206 bushels came through the canal, against 114,863 bushels in May, 1915, and rye, of which 132,000 bushels came through into Montreal, as against none at all in 1915 for May. Other figures for May, 1915 and 1916 respectively, are as follows: Corn, 415,041 and 185,340 bushels; oats, 2,200,-840 and 1,298,615 bushels; flaxseed, 117,-000 and 99,598 bushels; decreases in every case. This decrease occurs at a time when there is lots of wheat to ship and the port in a splendid position to handle it.

The total coal received in the harbor through the Lachine Canal last month was 245,842 tons, as against 144,952 tons in May, 1915, or an increase of 100,890 tons.

General Produce

In the statistics of produce carried there are decreases in every item except cheese, which increased from 15,498 boxes in May, 1915, to 18,649 boxes of cheese in May, 1916, an increase of 3,-151 boxes. In other items the disparity is most startling in the case of flour where 22,639 sacks were brought down the canal in May, 1915, and none came last month. Figures for May in the two years being considered were as follows for the other items: Eggs, 4,469 cases in 1915 and 4,186 cases last month; butter, 567 packages in 1915 and 308 packages last month; apples, 83 barrels in 1915 and none last month.

Vessel Trips

In considering the number of trips made by vessels through the Lachine Canal the following figures show a steady diminution ever since the year 1913 for May: 1910, 1,256 trips; 1911, 1,173 trips; 1912, 1.051 trips; 1913, 1,307 trips; 1914, 1,292 trips; 1915, 1,070 trips; and 1916, for May, 968 trips. Thus, the surprising result is shown that the Lachine Canal was used by fewer vessels last month than it had been for the same month six years ago or any year since.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Hamilton, Ont.—The W. T. Rawleigh Co., will proceed with the erection of a factory here.

Hamilton, Ont.—The Canadian Steel & Wire Goods Co., will build an extension to their factory.

Oshawa, Ont.—The McLaughlin Motor Car Co., and the Chevrolet Motor Car Co., contemplate making extensive developments to the factory here.

Fassett, Que.—The Standard Chemical Iron & Lumber Co. is building a new factory to replace the one recently destroyed by fire with a loss of $75,000.

Joliette, Que.—The Joliette Steel Co., has purchased a building which is being remodeled for the manufacture of castings by the converter process.

Stratford, Ont.—The R. M. Ballantyne Co. will build a power plant at a cost of $10,000, and will install new engines, boilers, and other accessories.

Hull, Que.—The Hull Iron & Steel Foundries, is building an addition, 90 x 150 ft., to its foundry, at a cost of $30,000, to be used as a small castings department.

Vancouver, B.C.—The Granby Consolidated Mining & Smelting Co., will install a steam power plant at the Anyox smelter to be used as an auxiliary during the winter.

Clayburn, B.C.—Large extensions are being made to the plant of the Clayburn Firebrick & Clay Co., which will require machinery to double the capacity of the plant. W. H. Armstrong is president.

Hamilton, Ont.—The Peerless Weaving & Belting Co. has leased the factory of Ludlam-Ainslie Co., and will instal machinery for the manufacture of leather belts, automobile accessories, etc.

Simcoe, Ont.—L. Frick & Son, will be in the market for the following machinery for a planing mill which is being erected there: Planer, sticker, rip-saw, rip-table, one 40 h.p. motor, shafting, belting, etc.

Vancouver, B.C.—The Nicola Mining & Smelting Company's property at Stump Lake, near Kamloops, has been acquired by a Seattle syndicate. New machinery will be installed including a 100-ton concentrator.

Dartmouth, N.S.—The Williston Steel Foundry, Halifax, N.S., is building a foundry here for the manufacture of crucible steel castings. The furnaces to be installed will be of the patent tilting design, using coke for fuel under forced draft. The plant will cost $16,000.

Hamilton, Ont.—The controlling interest of the Maple Leaf Auto & Supply Co., has been secured by W. Ellis, who is having a plant erected on Barton St. for the manufacture of metal garages, gasoline tanks, automobile parts, metal specialties, etc. H. J. Wise is manager.

New Toronto, Ont.—The new factory which the Goodyear Tire & Rubber Co., propose building here will cost about $1,500,000. The plant will cover a site of 27 acres and the main building will be 560 ft. long by 100 ft. wide with four floors and basement.

Victoria, B.C.—A bond guarantee for $40,000 has been given the French Complex Ore Production Co. to enable it to construct an electrolytic zinc smelting plant at Nelson. The company agrees to lease the old Fairview zinc plant and to operate it for the purpose of developing and commercially demonstrating its process for the treating of complex ores.

Essex, Ont.—A new tractor company to be known as the Doyle-Dennert Tractor Co., has been formed here and has been incorporated with a capital of $150,000. Dr. Doyle is president, W. G. Doyle, vice-president, W. J. Nesbitt, secretary, and Mildred Dawson, treasurer. E. C. Dennert is general manager. The company purposes manufacturing tractors for agricultural purposes and for scraping roads.

Vancouver, B.C.—The Slocan Star Mines, are pushing construction of the aerial tramway to connect the mine with the C. P. R. terminal at Sandon. The additional machinery for the mill is being received, and will shortly be installed, making a better separation of the zinc and lead products, and enabling higher grade concentrates to be shipped. Arrangements are being made to construct a power plant at Sandon, to be ready for operation by the period of low water in the fall. This plant will enable the mill to be operated all the year round.

Vancouver, B.C.—The Tonopah-Belmont Development Co. are constructing a dam at the Surf Inlet mine on Princess Royal Island. This dam will supply power to develop 1,500 h.p., and as soon as this power is available the installation of the first unit of the mill and mining plant will be pushed forward. It is proposed to construct an electric railway to connect the mine with the head of navigation, so that the machinery can be placed on the ground. A transmission line to convey power from the new power plant to the mine will have a length of seven miles.

Chicoutimi, Que.—The Ha Ha Baie Sulphite Co., has awarded a contract for the construction of a paper pulp plant at Bagotville, Que., to the J. G. White Engineering Co., of New York. Work on the site, which is on Ha Ha Bay on the Saguenay River, and which will occupy about five acres, has been begun and it is expected that the plant will be producing pulp early in 1917. The initial installation will have a capacity of 120 tons of sulphite pulp per day. J. E. A. Dubuc is president of the Company.

Vancouver, B.C.—The Canada Copper Corporation, which is the holding company for the British Columbia Copper Co., has important plans for the equipment of the Princess Alice camp on Copper Mountain, and its addition to the copper producers of the province. The plans provide for an outlay of $2,500,000 on the erection of a mill, and the installation of transportation and mining equipment. A working tunnel will be driven to open up the ore deposits for the economic extraction of the ore, and this will be connected with the surface by the shaft which is being deepened to the tunnel level. This tunnel will be 2,000 feet in length. The work will be completed by fall, and $400,000 has been set aside to cover the cost.

Electrical

Palmerston, Ont.—Hydro-electric power was inaugurated here on June 6.

Scarborough, Ont.—The Scarborough Township Council contemplate installing a hydro-electric system. The Village of Agincourt will be included in the system.

Niagara Falls, Ont.—Arrangements are being made by the Stamford Township Council to submit to the voters the proposal of the Hydro-Electric Commission to purchase the lines of the Ontario Distributing Co. in Stamford and Niagara townships.

If any advertisement interests you, tear it out now and place with letters to be answered.

General Industrial

Hamilton, Ont.—The Mercury Mills will build a factory here.

Brantford, Ont.—The Royal Paper Box Co., will build a factory at a cost of about $12,000.

High River, Alta.—The co-operative farmer's elevator at Federal has been destroyed by fire which started in the engine room.

New Westminster, B.C.—The Candian Products a newly organized concern, has taken over the business of the Duchesnay Packing Co. at Ladner, and will build an evaporating plant at a cost of about $30,000.

Municipal

St. John, N.B.—The city council proposes to make extensions to its waterworks plant and system to cost $230,000.

Sherbrooke, Que.—The City Council has passed a by-law making it compulsory for all manufacturing plants in the city using soft coal to install smoke consumers.

Winnipeg, Man.—The city council will apply to the Dominion Government for a lease of Slave Falls on the Winnipeg River in order to make further extensions to the city's power department.

Tenders

Toronto.—Tenders will be received by the Board of Control, up to July 4, 1916, for the supply and delivery of one 8-in. water-meter. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Vancouver, B.C.—The undersigned will receive tenders up till June 28, for the purchase of the following lap welded steel pipe, manufactured by the National Tube Co., Pittsburg, Pa.; 20,000 lin. feet 6-in.. 45,000 lin. ft. 8-in.. 10,000 lin. ft. 12-in. James Stuart, City Purchasing Agent.

Toronto, Ont.—Tenders addressed to the secretary-treasurer of the Board of Education, will be received until June 15, 1916, for oil-burning apparatus for steam boilers at Earl Grey school, and self-feeding, coal burning apparatus for boilers at Queen Alexandra school. Specifications may be seen and all information obtained at the office of the superintendent of Buildings, City Hall, Toronto.

The Pas, Man.—Tenders, addressed to H. H. Elliott, M.D., secretary-treasurer of the town of The Pas., Man., will be received up to June 22, 1916, for the supply and delivery of the following machinery and materials:—Tender "A"—For the supply and delivery of two sewage life pumps. Tender "B"—For the construction of a sewage lift chamber. Plans and specifications may be seen at the office of Murphy & Underwood, consulting engineers, Saskatoon, Sask., and the resident engineer, The Pas, Man.

Toronto, Ont.—Tenders will be received up to June 20, 1916, for the supply of the following 3 motor combi:nation hose and chemical engines; 1 motor tractor for hook and ladder at Ossington avenue fire hall; 1 motor truck for delivering supplies and hauling coal for fire engines; 1 motor combination salvage and chemical truck; 1 motor hook and ladder truck. Specifications of the above can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide street fire hall, Toronto.

Contracts Awarded

Toronto, Ont.—McGregor & McIntyre will supply the steel work for the Goodyear Tire & Rubber Co., factory at New Toronto.

Walkerville, Ont.—Wells & Gray, of Toronto, have been awarded the general contract for the new Collegiate Institute at $165,000.

Guelph, Ont. — Contracts have been awarded to Secord and Son, for an addition and alterations to the chemical building at the Ontario Agricultural College. The alterations will cost about $15,000, and an immediate start is to be made.

Orillia, Ont.—The Water, Light and Power Commission have awarded the contracts for the electrical machinery for the new power plant at the Swift Rapids to the Canadian General Electric Co. The contract price for two units, with a capacity of 3,600 h.p., is $68,000: for three units, with a capacity of 5,400 h.p., $81,000. The decision as to whether two or three units shall be installed has been deferred until the negotiations with the Hydro-Electric Commission for supplying them with the additional power required by their Severn system have been completed.

Refrigeration

Kaslo, B.C.—P. Burns & Co. will equip their branch market at Kaslo with a 1-ton Armstrong refrigerating machine.

Riondel, B.C. — The New Canadian Metals Co., is having installed a 1-ton refrigerating and ice making plant furnished by the Armstrong Machinery Co., Spokane, Wash.

Silverton, B.C.—Herman Clever will have his meat market equipped with a 1½-ton refrigerating machine, furnished by the Armstrong Machinery Co., Spokane, Wash.

Ford, Ont.—The Westgate Ice Cream Co., it is reported, has had its ice cream factory equipped with a 6-ton "York" refrigerating plant and dry hardening system.

Vancouver, B.C. — The Ocean Falls Pulp & Paper Co., will install a 7-ton refrigerating machine, contract for which was let to the Armstrong Machinery Co., Spokane, Wash.

South Vancouver, B.C. — P. Barker is having his meat market equipped with a 3-ton refrigerating machine, furnished by the Armstrong Machinery Co., Spokane, Wash.

Bella Bella, B.C. — The East Bella Bella Cannery, north of Vancouver, is having its cannery equipped with a 5-ton refrigerating machine, contract for which was let to the Armstrong Machinery Co., Spokane, Wash.

Trade Gossip

Lyall Board Re-elected.—At the annual meeting of the P. Lyall & Sons Construction Co., held in Montreal recently, the board was re-elected as follows: William Lyall, president; Traill Oman Lyall, vice-president; J. N. Greenshields, K.C., the Hon. Robert Mackay, H. Wyndham Beauclerk, John McKergow.

The Metals Coating Co., of Canada are operating a demonstrating laboratory at 90 St. James street, Montreal, for the purpose of demonstrating the "Schoop" method of metallic deposition. The company have the exclusive rights in Canada for this process which is being operated under the supervision of T. Stansfield Worthington, who has for some time been associated with its development.

Steel Co. of Canada.—It is expected that the Steel Company of Canada will soon complete the installation of its three new open-hearth furnaces, also its presses for the manufacture of 8-inch and 9.2 inch shells, and will then begin to operate same. The three new hearth furnaces will increase the output of steel by 300 tons per day, or about 33 1-3 per cent. It is understood that the output will then be at the rate of 1,200 tons of steel per day. The company is also making further extensions involving an expenditure of $1,000,000 during the pres-

Have you ever asked the question: "What assurance have I that this pay-roll is OK?"

Right off the bat we make this statement: "Any 'OK' you may have is from a 'human factor,' and unless you use an International Time Recorder, you have no REAL protection."

It's a cold-blooded, unfriendly machine. It can't think, and it can't make mistakes. All it does is to see that you get every minute of working time you pay for.

Printed, unchangeable time records are made automatically, under lock and key, and these form your weekly pay-roll sheets.

Your business may be unusual, but we can give you a Time and Cost-Keeping System that will exactly fit it. We are the largest makers of Time Recorders in the World. Write us to-day for new folders and prices.

OUR SERVICE DEPARTMENT. We maintain a Service Department at our factory, that is at the call of our users at any minute. This Department employs only expert mechanics, thoroughly trained on the mechanism of all our recorders. We urge our customers to have their time recorders inspected at regular intervals.

International Time Recording Company of Canada, Limited

Toronto: Anderson St. **F. E. MUTTON, Manager**

Montreal: W. A. WOOD, Sales Agent
Corner McGill and Cartier Streets

ent year. Work on hand will mean operating full time well into 1917.

Canadian Timber Values.—According to a recent Commerce Report the values of the various classes of timber produced in Canada in 1914, together with the values of the forest products, total $176,672,000, being divided as follows: Lumber, lath and shingles, $67,500,000; fire wood, $60,500,000; pulpwood, $15,500,000; posts and rails, $9,500,000; cross ties, $9,000,000; square timber exported, $400,000; cooperage, $1,900,000; poles, $700,000; logs exported, $850,000; tanning material, $22,000; round mining timbers, $500,000; miscellaneous exports, $300,000; miscellaneous products, $10,000,000.

Quebec Bridge Progress.—At the close of last year's work, there had been 46,000 tons of steel erected in the North Shore anchor and cantilever arms of the Quebec Bridge. As the total steel in the bridge will come to 65,000 tons, approximately 19,000 tons yet remain to be placed. The South Shore cantilever arm was started in April, 1916, and three weeks later the first panel adjacent to the main pier was well under way. The South Shore cantilever arm will be finished by September, 1916, when the bridge will be in readiness for the floating and hoisting of the suspended span. This span is 640 feet long, and 88 feet wide, and weighs, in the floating condition, approximately 5,000 tons.

Language Difficulty.—To overcome the language handicap, a lectureship in Russian has been endowed in Sheffield University. Liverpool University has had a Russian chair for fifteen years, and the Birmingham Chamber of Commerce has invited donations towards the endowment of a chair of Russian in Birmingham University. In Glasgow the Chamber of Commerce some time ago asked for subscriptions towards a fund of $2,500 for the establishment of prizes or scholarships to enable young men of approved qualifications to reside in Russia with a view to acquiring proficiency in the language, and a Russian class was opened at the Glasgow and West of Scotland Commercial College. For some reason or other the Glasgow public did not display much appreciation of the scheme, for less than $1,500 was subscribed. Birmingham has raised $40,000.

The Chemical Market.—The signs of stiffening in the markets for sulphuric acid, benzol, totnol and other explosive making bases are noticed, says, a New York despatch. The improvement is attributed to the prospect of large orders for such materials being placed within the next few weeks. For some time the markets for these chemicals have been dormant, but of late a steady inflow of small orders has been reported. While no definite inquiries for large tonnages have appeared, the trade has been given reason to expect that Russia, France, and possibly Great Britain will ask for bids on explosives and explosive ingredients in the near future. It is pointed out that the consumption of explosives by the belligerents has been enormous of late. The Verdun conflict, the Skager Rack fight and the new Russian offensive have consumed masses of such supplies and the Allies must renew purcheses abroad.

Railways—Bridges

Kelowna, B.C.—The C. N. R. will probably start construction of the proposed branch from Kamloops to Okanagan, this summer.

Vancouver, B.C.—Construction work on the Pacific Great Eastern Railway is to be started at both ends of the line as soon as sufficient men can be assembled for the work.

Personal

George A, Slater, shoe manufacturer, was elected chairman of the Montreal branch of the Canadian Manufacturers' Association.

Sir William Price, who is leaving for England in command of his battalion, is, it is understood, giving up the chairmanship of the Quebec Harbor Commission.

C. C. Johnston, of London, Ont., formerly resident engineer here for Chipman & Power of Toronto has joined the Canadian Copper Co. at Sudbury, Ont.

Sir George E. Foster, Minister of Trade and Commerce, has arrived in London, England. Sir George, who has been made a Privy Councillor, will attend the Allies Economic Conference at Paris with other representatives of the British Government.

Charles R. Scoles, a prominent railroad man of New Carlisle, Que., died recently in Bermuda. The deceased was born at Grantham, England in 1856. He was connected with various railway enterprises in Eastern Canada. In 1890 he was appointed manager of the Salibury & Harvey Railway. In 1900 manager of the Atlantic and Lake Superior Railway and in 1911 manager of the Quebec Oriental and Atlantic, Quebec and Western Railways.

Sir Hay Frederick Donaldson, who was recently lost on H.M.S. Hampshire, was technical adviser to David Lloyd George, Minister of Munitions. He visited Canada last fall on the invitation of D. A. Thomas (Baron Rhondda) to study the possibility of manufacturing heavy ordnance in this country. He was formerly chief superintendent of ordnance at Woolwich Arsenal and was prominent in the engineering world, being past president of the Institute of Mechanical Engineers and a member of the Iron and Steel Institute, and of various engineering societies. He was born in 1856.

New Incorporations

The Maple Leaf Tires has been incorporated at Ottawa, with a capital of $500,000 to manufacture tires and rubber goods of all kinds. Head office to be situated at Toronto. Incorporators: H. C. Long, R. K. Grimshaw, and E. J. Swift, all of Toronto.

Woodsplitter, Ltd., has been incorporated with a capital of $100,000 to manufacture certain machines designed to saw, split and otherwise prepare wood and lumber. Head office at Toronto. Incorporators, A. E. Cooper, C. Allan and R. McCulloch all of Toronto.

The Port Hope File Mfg. Co., has been incorporated at Toronto with a capital of $40,000 to carry on the business of machinists, iron founders, and file makers at Port Hope, Ont. Incorporators, W. G. Brown, W. Embleton and E. G. Fogarty all of Port Hope.

The Tobacco Products Corp. of Canada, has been incorporated at Ottawa with a capital of $250,000 to manufacture tobacco products and by-products. Head office to be situated at Montreal. Incorporators, A. Wainwright, A. H. Elder and F. W. Hackett all of Montreal.

The Canada Stove & Foundry Co., has been incorporated at Ottawa with a capital of $1,500,000 to carry on the business of iron masters, steel makers, Head office to be situated at Montreal, Que. Incorporators, E. R. Parkins, R. E. Allan and F. W Tofield all of Montreal

La Compagnie Chs. A. Julien, has been incorporated at Quebec with a capital of $145,000 to manufacture and repair all kinds of machinery and agricultural implements, etc., at Port Rouge, Que. The incorporators are Chs. A. Julien, Odilion Riche and Celien Delisle, all of Port Rouge, Que.

The Barnes Construction Co. has been incorporated at Ottawa, with a capital of $5,000, to manufacture automatic sprinklers, fire extinguishing and fire prevention apparatus of all kinds. Head office to be situated at Montreal. Incorporators: F. G. Bush, F. B. Common, and G. B. Drennan, all of Montreal.

The St. John Dry Dock & Shipbuilding Co., has been incorporated at Ottaway with a capital of $1,000,000 to carry on the business of a general contracting construction and developing company for the construction and equipment of public works. Head office to be situated St. John, N.B. Incorporators, R. T. Heneker, H. B. Chauvin and H. E. Walker all of Montreal.

The Canadian Forestry Products, has been incorporated at Ottawa with a capital of $9,500 to carry on business as manufacturers, of pulp wood, cord wood and other forestry supplies together with aal by-products including wood, alcohol and all chemical products and compounds. Head office to be situated at Montreal. Incorporators are L. H. Boyd, A. R. Johnson and Arthur Ross all of Montreal.

Building Notes

Galt, Ont.—The Bell Telephone Co., contemplate erecting a new exchange building here.

Winnipeg, Man.—The Stovel Co., has begun the construction of its new printing plant at the corner of Dagmar and Bannatyne avenue, to replace the building recently gutted by fire. The new plant will be eight storeys, three to be rushed to completion at a cost of $200,000 for present requirements. These initial three storeys will have a floor space of 84,000 square feet.

Wood-Working

Elmira, Ont.—A one-storey concrete building, 70 x 90 ft., is being built by Bauman & Letson, to replace their planing mill recently destroyed by fire.

Marine

Lunenburg, N.S.—John McLean & Sons, expect to start work shortly on a steamer intended to replace the wrecking steamer Bridgewater. Both shipyards are pretty well filled up with work at present.

Catalogues

Electric Tools.—The Stow Mfg. Co., Binghampton, N.Y., have issued a new booklet entitled "Portable Tools of Proven Value." The booklet is fully illustrated and contains descriptive matter covering various types of portable electric tools, motor-shaft combinations, flexible shafts of all sizes, etc.

Rotary Surface Grinders made by the Persons-Arter Machine Co., Worcester, Mass., are illustrated and described in a Bulletin recently issued. The model A type which is the subject of this Bulletin is shown in 8 in. and 12 in. sizes. The principal features embodied in the construction of this grinder are explained in the reading matter and also by means of drawings reproduced. A specification is also included.

Gate Valves.—The latest catalogue issued by the Nelson Valve Co., Philadelphia, Pa., deals with extra heavy steel gate valves for superheated steam and other power plant service. This is a very comprehensive booklet on the subject and is a handy reference for specifications and prices. The various types of valve are illustrated and described while tables give the price and principal dimensions for each size. Copies of this catalogue will be gladly furnished on request.

A Manual for Operating Lodge and Shipley Lathes is the title of new Bulletin No. 140, issued by the Lodge & Shipley Machine Tool Co., Cincinnati, Ohio. This manual is for the operator's guidance in using Lodge & Shipley engine lathes and attachments. It gives brief descriptions of different parts of the lathe, instructions for operating, suggestions for handling work and grinding tools, etc. All parts of the lathe are described in detail and exceptionally clear half-tones and diagrams show the general construction. This is an extremely useful manual for users of this type of lathe, who may obtain copies by writing the Lodge & Shipley Machine Tool Co.

Regenerating Sulphated Accumulator Electrodes.—In the course of a research on lead sulphate and lead, G. A. Perley and C. W. Davis, of Durham College, New Hampshire, observed that sulphated electrodes of secondary batteries could be regenerated by being placed in caustic soda, without the use of an external current. The method, however, was not satisfactory, and after trying various solutions — sodium sulphate, chlorate, phosphate, carbonate, tartrate, etc., with or without the addition of caustic soda—they found that the old method of regeneration by sulphate of sodium was, after all, the best. They advise the placing of two additional positives next to the two outer negatives, in order to hasten the regeneration of these latter electrodes. The regeneration is effected by supplying the ordinary charging current for about 60 hours.

INDEX TO ADVERTISERS

Manufacturing the Six Inch High Explosive Shell

Staff Article

The accompanying article may be reckoned as the first of a series dealing with the larger type shell now being produced in numerous Canadian metal-working plants, and while the equipment detail and operation methods employed differ somewhat from those relating to the shrapnel and small high explosive, it will be clearly evident that experience of these latter has contributed in no insignificant degree to the bigger shell production achievement.

THE manufacture in Canada of the heavier class of shells promises to equal, if not surpass, the remarkable record made in the production of the smaller types. Although the successful manufacture of the larger shells necessitated the installation of much heavier equipment than previously needed, many shops in various parts of the Dominion are now producing and shipping. In many respects, the processes of production on all shells are similar, but the equipment and method of handling, as well as various other details differ to a great extent.

The accompanying article was compiled from data personally secured in one of our leading metal working plants.

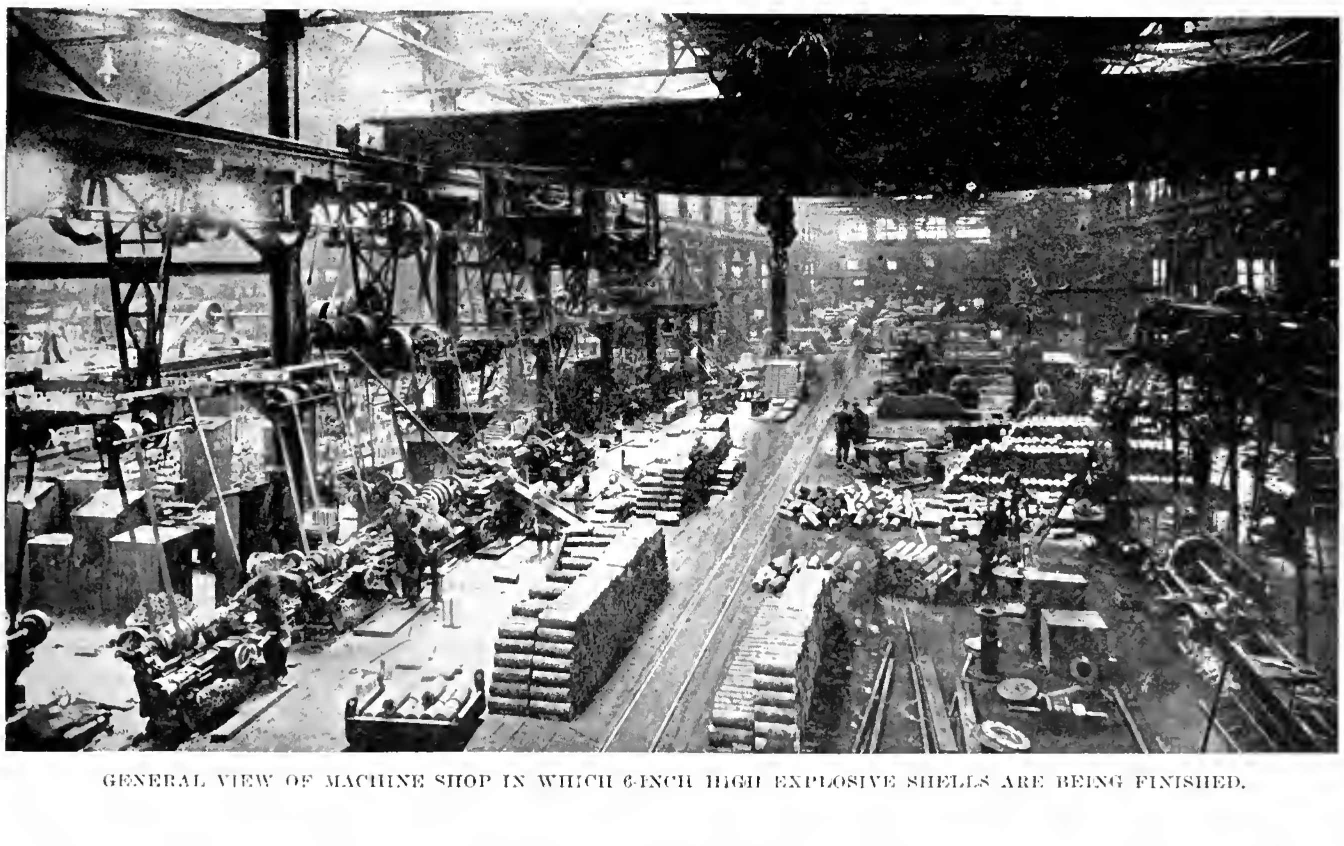
Casting and Forging the Billet

Two methods of producing the steel billet (from which the shell is forged), are being employed, the billets are cut from a rolled bar or are produced directly from a cast ingot. While a great quantity of shells are made by the former process, the greater proportion, especially of the larger sizes, are produced by means of the latter. When the latter process is adopted, the specifications call for an amount of metal to to be cut from the upper end of the ingot, equal to 20 per cent of it's length, to obviate "pipe" and blowholes. For this reason it is necessary to prepare much more metal than actually required, as the steel in each ingot will be approximately 22 pounds in excess of that needed to make the shell. After the ingots have been cast, the top portion is parted down to a section in the center equal to about 20 per cent of the cross sectional area, this portion being afterwards broken off for examination of carbon content and fracture.

The billets are next placed in a crude oil furnace, 30 at a time and heated to a temperature of about 2,100 degs. F. It is essential, to best results, that the billets be heated to the proper temperature, and evenly throughout. When the billets are unevenly heated there is the possibility—especially if the forging punch should be a little loose, of producing a shell having eccentric walls. When the billets are sufficiently heated, they are removed from the furnace with a long pair of tongs, and, by aid of an overhead monorail which supports the billets and tongs, are carried to an adjoining press for forging. Before the billet is placed in the die, however, it is dropped on a large plate, where the scale on the surface is quickly removed with scrapers.

The billet is now raised from the plate and dropped in the die, which is about 1-16 in. larger than the heated billet. Just before the punch descends, a small quantity of coal dust is thrown on top of the billet, the purpose of this being to create a gas below the punch which aids in its withdrawal after the billet has been pierced. Sometimes however, the punch will have a tendency to lift the shell from the die, in which case, provision is made for stripping the shell by means of a plate working in slides on the top of the die. All presses are equipped with water sprays and streams for cooling the punches and dies. Punches are lubricated with plumbago and oil; and under favorable conditions will produce from 200 to 300 shells before renewing.

This shop is equipped with seven 200-ton Wood presses, which have a capacity of 250 shells each in 8 hours—



GENERAL VIEW OF MACHINE SHOP IN WHICH 6-INCH HIGH EXPLOSIVE SHELLS ARE BEING FINISHED.

shop operating on three shifts of 8 hours each. Ferguson furnaces are used throughout, and to insure continuous operation, three furnaces serve each 6 inch press. An approximate estimate of production in this plant is about 4500 forgings for 6 in. shells per day. In addition to the 6 inch shell equipment, this plant is making 8 inch and 4.5 inch shell forgings. One 350 ton press operates continually on 8 inch, and several are working on the 4.5 inch shells. Four 350 ton accumulators loaded with iron ore and slag are operated by four geared Dean pumps, direct driven by 200 h.p. C. G. E. motors.

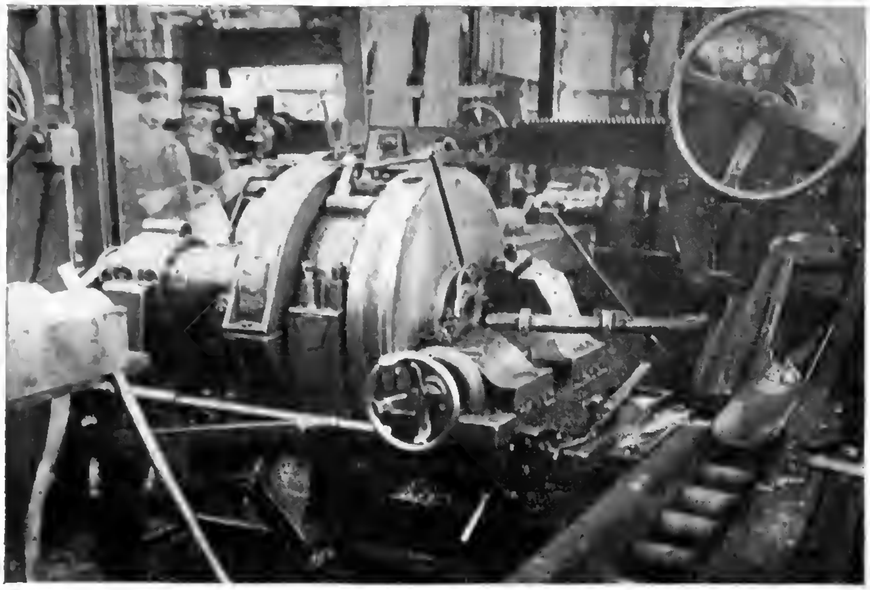


FIG. 1. LAUGHLIN-BARNEY CUTTING-OFF MACHINE TRIMMING OPEN END OF SHELLS.

Machining The Shells.

After the shells have cooled from the forging operation, they are taken to another department and inspected for concentricity of wall thickness, length and surface defects. Those shells which have developed faults from the forging process are placed to one side for future consideration. The percentage of rejected shells at this stage however, is very small; in fact, some of those that are discarded are later found to come within the limit of tolerance. As the shells are inspected, they are placed in separate piles, those of the same heat being kept in one pile. As the rough shells accumulate very fast, and there arises the possibility of the series becoming mixed, each lot is stenciled with red paint, before passing on to the machining operations. Fig. 1 shows a general view of shop where preliminary inspection takes place.

Cutting Rough Shells to Length

The first machining operation on the 6 inch high explosive shell is that of cutting-off the open end. This is performed on eight Laughlin, Barney Machine Co. cutting off machines, one of which is shown in Fig. 1. The shell is placed on the wooden block which travels on wood rollers, and is then slid forward. The table is of such a height that the bore of the shell passes over the swinging arm carried in the bracket which is moved along the rail above the machine by means of a rack and pinion. A stop is arranged on the rail so that the swinging arm acts as a gauge for setting the shell in proper position in the chuck. Each machine is capable of handling from 80 to 100 shells per day of 10 hours.

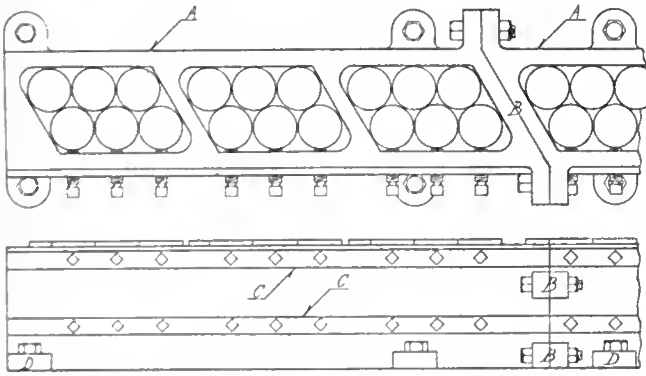

FIG. 2. PLANER JIG FOR FACING SHELL BASES.

Roughing-off the base is the second operation. There are at present four large Niles-Bement-Pond planers working on this operation, in addition to several lathes. A sketch of the jig used for holding the shells while facing off the base is shown in Fig. 2. Two jigs are used on each planer, made up of two sections and joined together as shown at B. The jig is secured to the table by means of the lugs D, the frame being reinforced for the clamp screws by the ribs C. When two heads are used—which is possible when the cut is not too heavy—the load of 72 shells can be finished in approximately 3 hours. However, it sometimes happens that the amount of stock to be removed will be about 1¼ inches, in which case it is found necessary to use only one head, so that the time required to complete one load may take from 5 to 6 hours.

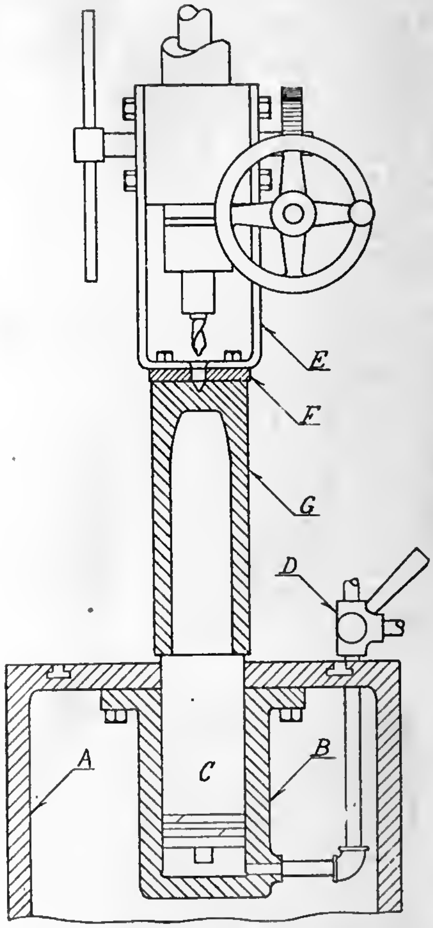

FIG. 3. CENTERING SHELL BASE ON DRILL PRESS.

Centering the Base on Drill Press

The third operation, that of centering the base, is accomplished in an upright drill press. An interesting feature in connection with this operation is the method of gauging and handling the work. The shells are placed upon the table of the machine, which is of the square box type, and fitted with an air cylinder secured to the lower part of the table, as shown in Fig. 3. The piston C, when released, comes just below the level of the table, so that no obstruction is offered when the shell is being moved into position. When the shell is in the

desired location, air is allowed to enter the cylinder B, by operating the three way valve D, and the shell is forced up against the gauge disc F, which is secured to the bracket E, which is bolted to

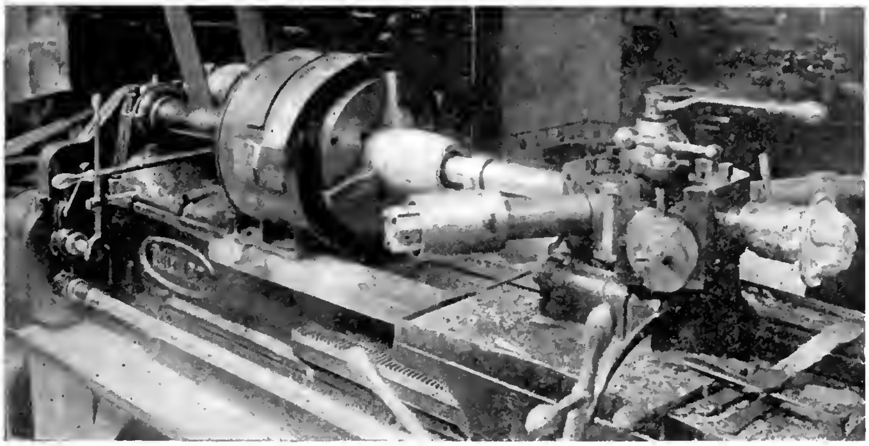

FIG. 4. SHELL FACING, BORING AND TAPPING ON BULLARD LATHE.

the drill press frame as shown. Owing to slight variation in the diameter of the rough shell, the flat disc was adopted, and for this reason it is sometimes nec-

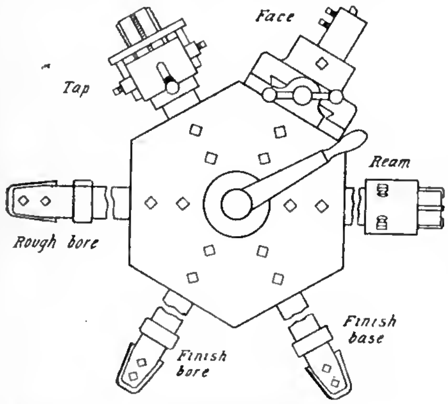

FIG. 5. TOOL ARRANGEMENT FOR SHELL BORING.

essary to apply the air a few times before the shell is in a central position.

Rough Turn and Bore

When the shells have been centered, they are subjected to the rough turning operation, which is performed on twenty-six LeBlond heavy duty engine lathes. Machining the cylindrical portion of the 6 inch shell is very similar to that of the smaller shells; the body being rough turned to a diameter of about 6.2 inches over the entire length, and the profile of the nose contour roughly formed. It is occasionally found necessary, due to excessive wall eccentricity, to rough out the interior of some shells before the final boring operation.

Face, Bore and Tap

The sixth operation is that of machining the bore. Twenty-four Bullard single purpose machines are used on this, a general view of one of these being shown in Fig. 4. The interior of the shell is completely finished at this setting, and the cycle of operations is as follows:—Placing shell in chuck, which is of the three jaw universal type; rough boring to a diameter of about 3.58 inches by a flat cutter held in a long rigid boring bar; rough lower tapered section at base of shell which recedes from 3.58 to 2.7 with a corner radius of 0.8 inches; finish bore to a diameter of between 3.62 and 3.64, with corresponding dimensions for the lower tapered portion. The section at the nose of the shell for the socket thread is now reamed, the nose being afterwards faced off to the desired dimensions: This last operation is accomplished by means of a tool held in a short bar, which in turn is firmly secured in a slide operating in a vertical direction by means of a fine pitch screw. The final move is the tapping of the nose with a Murchey 3.8 inch, 14 thread, right hand collapsible tap. A sketch of the tool layout is shown in Fig. 5.

Preparing Shell for Socket

Following the boring operation, the interior is thoroughly cleaned by sandblasting to remove all traces of grease, and also prepare the surface for the application of a coating of shellac, which is applied just previous to the painting process. To insure accuracy in further machining operations and reduce to a minimum the possibility of eccentricity between the inside and outside diameters, the shells are recentered by placing on a special expanding mandrel held on the spindle of a lathe. The hole for the set-screw, which secures the steel socket, is then drilled and tapped, and the nose of the shell sized by means of a hand tap. The shell is now ready

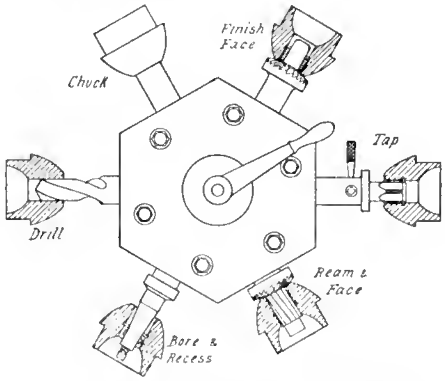

FIG. 7. TOOL LAYOUT FOR FINISHING SOCKET NOSE.

to receive the steel socket, which is finished in another section of the shop.

Machining the Steel Sockets

Before further operations on the shell can be proceeded with, it is necessary that the socket be placed in the nose, therefore, before describing the succeeding operations on the shell proper, it may be well to give a brief outline of the machining on the nose socket.

The first operation is boring and threading the nose to receive the fuse plug. A view of this operation is shown in Fig. 6, and the turret tool layout is illustrated in the sketch, Fig. 7. The cycle of operations is:—Chucking; rough drilling; bore and recess for tap clearance, ream and face, tap and finish face. The distance of the recess from the nose of the socket should be 1.2 inches, with a limit of 1/100 above or below. A variation of 5/1000 is allowed either way in the plain section of the bore on a neutral diameter of 1.895 inches. The diameter of the thread in

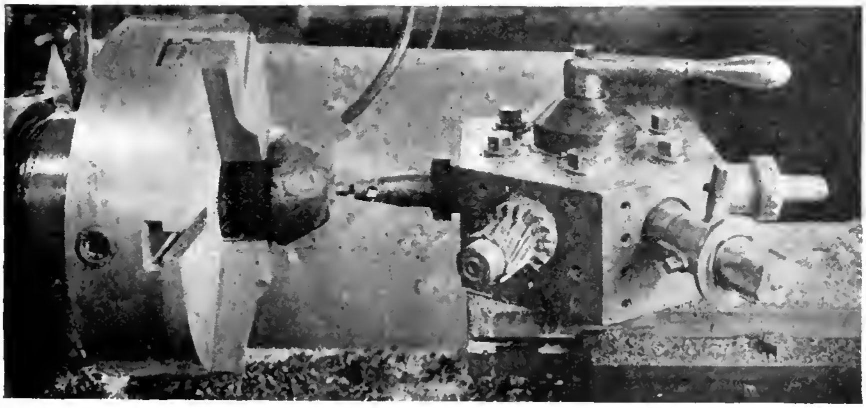

FIG. 6. MACHINING SOCKET NOSE ON BARDONS & OLIVER LATHE.

the nose of the socket is 2 inches, with an allowable limit either way of 3/1000; threads are 14 to the inch and right hand. Seven Bardons & Oliver single purpose single purpose unit handles on an average 450 sockets per day. On several occasions this has been increased to nearly 500. A 3.8 inch diameter, 14 thread Murchey collapsible die is used, the cutting dies requiring to be sharpened three or four times a day. Several sets are kept available, so that very little time elapses when dies are being replaced.

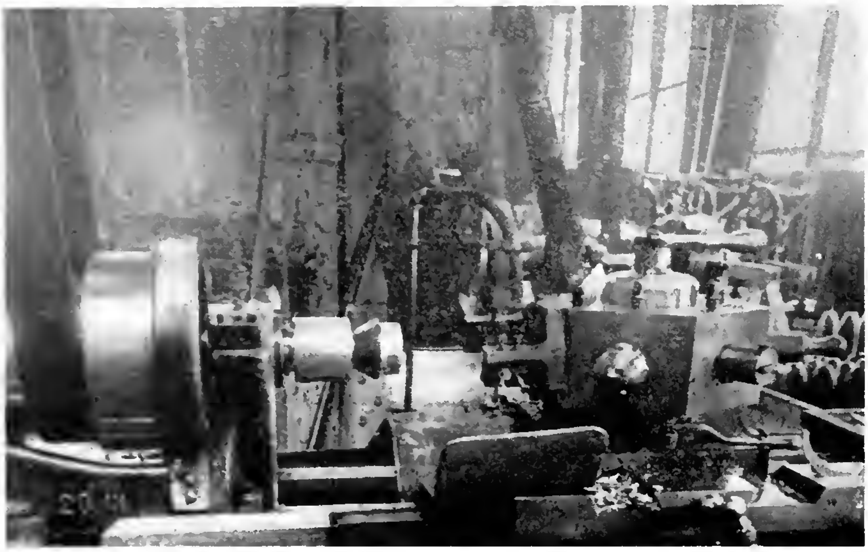

FIG. 8. TURNING AND CUPPING SOCKETS ON AMERICAN TOOL WORKS LATHE.

chucking lathes with Murchey collapsible tap are in operation, each with a capacity of 80 to 100 a day.

The socket is next removed from the chuck and placed on a threaded arbor secured to the spindle of a 20-inch American Tool Works Co. engine lathe. The various operations at this setting are:—Placing on arbor; turning the two diameters with two tools held in a special holder; facing shoulder and recessing for thread clearance; this is done with a small tool held in the rear extension of the special holder. Following this, the cup portion is cut out to a radius of 1.75 inches, while the end is faced off to a length from the shoulder of 1.55 inches, with a limit of 2/100 either way. The inner and outer edges are slightly rounded.

The next operation, that of threading the socket is performed separately on two machines; one of which, a Bullard

Finish Outside Diameter and Profile

The semi-finished sockets are screwed into the nose of the shell by gripping the body of the latter in a special chucking device secured to a floor stand. The socket is screwed in by means of a plug and three foot wrench. Following this, the shells are ready for finishing on the outside diameter and contour of the nose. A driving plug is screwed into the nose, the shell placed between the centres of an engine lathe, and is driven by the slotted chuck shown in Fig. 9. This sketch illustrates a simple and efficient arrangement for the completion of this operation. A series of rollers with a flexible cable in conjunction with a suitable cam are used to keep the cutting tool in the desired position. Upon the plate A, which is supported by two brackets extending out from the bed of the lathe, is secured the profile cam B. Instead of the cross feed screw being held in the saddle, it extends through and is held in the movable head C, which is free to travel in a direction at right angles to the lathe spindle, and is retained in proper alignment by the two studs D. The cable F, is secured at one end to the bracket G, and, after passing over the several rollers, is fastened to an eye-bolt in the weight L. When traveling on the parallel portion, the faces of the head C rest against the back edge of the saddle, and the depth of cut

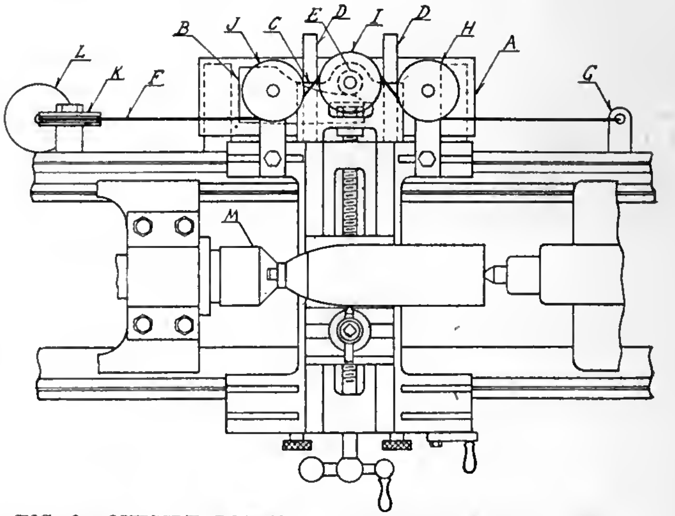

FIG. 9. OUTSIDE DIAMETER AND PROFILE TURNING ARRANGEMENT.

can be adjusted in the ordinary manner by means of the cross feed screw. When the tool is set in the proper position, the roller E will come in contact with the cam at the correct point, and, as the saddle advances, the profile of the nose is formed to the desired shape. About 24 lathes of American and Le Blond make are engaged on this operation, and each machine has an average of about 45 shells in 10 hours. The general run of tool steel is B-4, B-5, B-6 and Armstrong-Whitworth make.

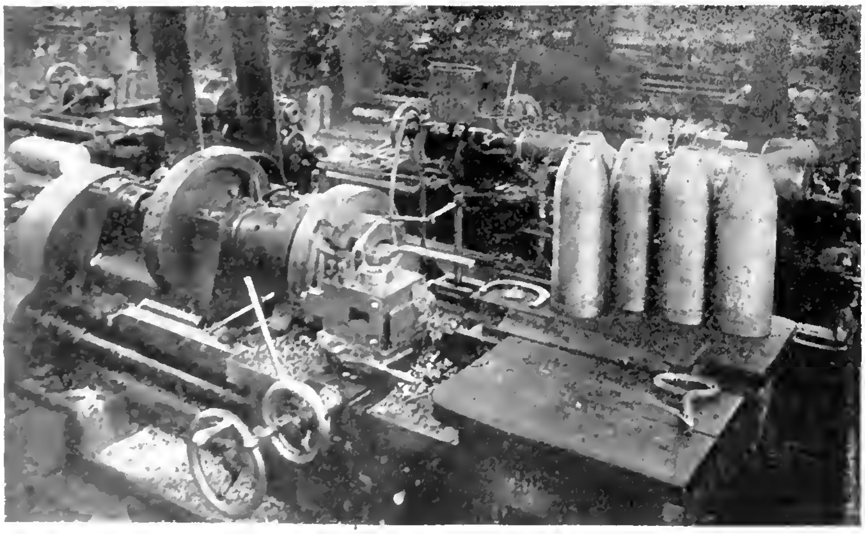

FIG. 10. GROOVING AND WAVING ON NORWOOD ENGINEERING CO. LATHE.

Facing to Weight

Following the finish turning operation, the shells are weighed, being usually found too heavy. The specified weight at this stage of production is 88.8 pounds. and the allowable variation must not ex-

FIG. 13. JENCKES MACHINES TURNING COPPER BANDS.

ceed 8 ounces above or below. In facing off the base to bring the shell to the required weight, an approximate estimate of stock removal is about 1/64 for each 2 ounces.

Grooving and Waving Operation

A view of this operation is shown in Fig. 10. Eight Norwood Engineering Co. lathes are employed, each with a capacity of about 200 shells in 24 hours. The tooling to produce the copper band groove is similar to that used on the

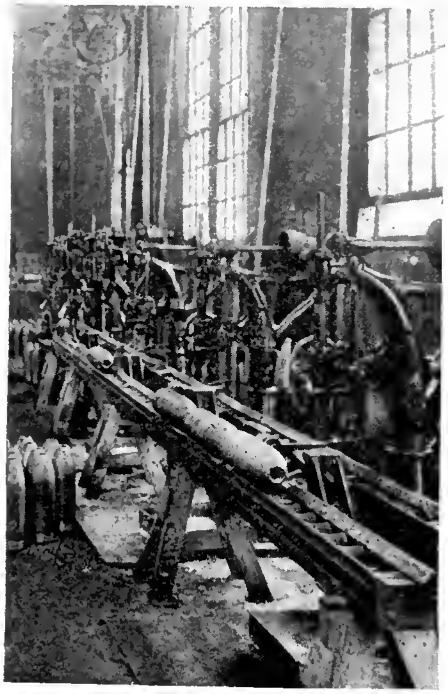

FIG. 11. DRILLING SCREW HOLES IN NOSE SOCKET AND SHELL.

smaller sized shells; that is, roughing, waving and undercutting. The latter is accomplished by means of two small tools held in a slide, secured to a holder and operated by a small eccentric. The cam is fastened to the face of the chuck and slots are provided for the free movement of the chuck jaws. Most of the chucking operations require an extension to the lathe spindle, and to insure sufficient rigidity, this addition is amply supported in a suitable steady-rest. To facilitate the handling of these 6-inch shells, all chucking operations are aided by specially constructed slides for placing the shells in, and removing them from the chucks. This device is shown in the right foreground of Fig. 10, and consists of a table placed over the bed of the lathe. In this table is placed the sliding block upon which the shell is placed. To increase the leverage of the cross feed handle, a one-half inch rod is used in holes previously drilled.

FIG. 14. GENERAL VIEW OF ASSEMBLING ROOM.

Boring and Recessing Base

As the base of all shells, during the firing from the gun barrel is subjected to enormous pressure set up by the rapid expansion of the propelling gases, it is essential that the metal there shall be of such a nature as to avoid any possibility of these gases penetrating to the explosive charge within the shell. For this reason it is deemed advisable, if not absolutely necessary, to remove a certain portion of the metal at the base (which is often found to have developed imperceptible defects, during the forging operations), and insert a steel disc, that will have its grain at right angle to the axis of the shell. The steel used in these plates must be free from laminations, flaws, cracks, surface or other defects and be uniform in structure. The dimensions of this disc for the 6-inch shell are a diameter of 4.5 inches, with a thickness of one-half inch. The recess for this plate is cut out in nine 20-inch American engine lathes, fitted with special turrets and three jaw universal chucks. The metal is first cut out with a broad nosed tool, bored to the desired diameter, faced and recesses for thread clearance.

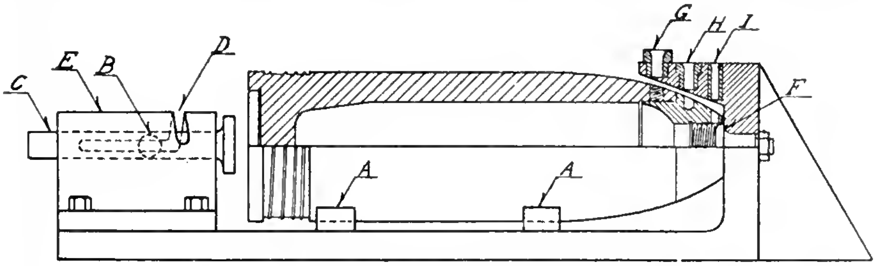

FIG. 12. JIG FOR DRILLING HOLES IN SHELL NOSE.

Drill Key and Set Screw Holes

The shells are now taken to a row of six drills—three Rego and three Cham-

pion Blower and Forge, where the holes for the key and the fuse set screw are drilled and tapped. These drills, as shown in Fig. 11, are fitted with special jigs and roller runways to facilitate the passage of the shells from one operation to another. The key hole for removing the socket has a diameter of .375 inch, and the fuse holder is a 1/4 grub screw. A sketch of the drill jig is shown in Fig. 12. The shell is placed on the two vee blocks A, and the handle B slid along the parallel slot. When the handle reaches the cam slot D, it is brought forward, thus forcing the head of the shaft C against the base of the shell, the shell in turn being moved forward to the proper position on the plug F. The three drill bushes are not all placed in the one jig, but are shown here in their relative position, as they would appear in their respective jigs.

Threading for Base Plate

The next operation is cutting the thread in the base. One Lees-Bradner and two Holden-Morgan thread milling machines are working continuously on this, each machine with a capacity of from 180 to 200 shells in ten hours. This thread, with a diameter of 4.5 inches, is 14 per inch, and is cut left hand. The purpose of the left hand thread is to counteract any tendency of releasing itself from its position when the shell is in flight. As the rifling of the gun barrel is right hand, the action of the rapidly revolving shell will consequently aid in keeping the base plate firmly in position. While this method of screwing the discs is now being employed, it will shortly be discarded and the riveted plate plan be adopted.

Applying and Finishing Base Plates

The base plates, which are punched from 7/8 plate, have a diameter in the rough of about 4 3/4 inches. To allow for holding in the chuck, the disc is recessed on one side to a depth of about 5/32 inch. They are held in a three-jaw chuck and faced and turned to the proper diameter and threaded. While the shell is held in a special floor chuck, the disc is screwed firmly into its place with a large pipe wrench. The surplus metal is then faced off to within about 1/16 of the shell base, the shell taken from the lathe and the plate thoroughly riveted by means of a pneumatic hammer. It is again placed in the lathe and the base turned off clean.

Press and Turn Copper Band

The copper bands, which are usually cut from tubing of suitable dimensions, are now driven over the end of the shell to a position in line with the groove. Previous to this, however, several nicks are cut across the waving ridges with a cold chisel, to allow the trapped air to escape when the band is being forced home. This is performed in a West banding press. Two or more applications of the pressure are required to complete the operation; the shell being slightly turned between each application.

Turning the copper bands to the desired dimensions is accomplished in three Jenckes band turning machines, two of these being shown in Fig. 13. The various operations for the completion of the band are practically the same as on the 4.5 shells, with the additional detail of undercutting a shoulder to a depth of .04 inch. This is performed by the small attachment placed on top of the ordinary cross slide and at the proper angle. The driving clutch and chuck are operated by compressed air, and each machine is equipped with a sliding block and table like that shown in Fig. 10.

Inspection and Assembly

The machining operations being finished, the shells are inspected and stamped on the base, assembled into series and passed along the bench for final weighing. The benches run the full length of the room, and, about midway, a space is provided where a large Toledo scale is placed, so that the shells can be conveniently rolled from their position on the bench to a suitable block situated in the centre of the scale table. The final weight should be 89 pounds, 3.5 ounces; with a limit of 2 ounces under and 7 ounces over. A general view of the assembling room is shown in Fig. 14.

Cleaning and Painting

The shells are thoroughly cleaned and shellaced on the inner surface. Particular care is required in this operation, so as to have a clean, smooth and well covered surface, as the chemical action of the explosive charge has a very deteriorating effect upon any uncovered portion. After the cap and set screws have been inserted, the shells are given a coat of good paint to protect the surface from the action of the corroding elements in transit or otherwise.

A NEW HIGH-SPEED TOOL STEEL

AN alloy which contains neither tungsten, molybdenum, nor cobalt, and which is claimed to give excellent high-speed tool-cutting quality, has recently been produced by Darwin & Milner, of Sheffield, England. They gave a demonstration at their works, during which the casting of the bars was witnessed. The steel, which is melted in an ordinary crucible furnace capable of yielding high temperatures, is run into either metal or sand moulds and cast to the form desired. When cool, and without any forging or heat treatment, the tools produced are ground on an emery-wheel (dry) and finished on a wet grindstone. They are then ready for immediate use. From this it will be seen there are no complicated forging and heat-treatment processes to go through, and as the tools obtained possess the correct hardness, a number of skilled operations are eliminated.

Makers' Tests

The tools cast were 1 1/4 in. square, but other sizes were exhibited, and some of them were seen in operation. The firm state that they are prepared to cast bars of any shape which are at present in use up to 4 in. square. They have tested the new alloy steel for cutting properties on high tensile steels, commercial steels, cast iron, and phosphor-bronze, and claim that it is equal in cutting properties to any high-speed tool steel on the market, but they have not yet carried out any exhaustive endurance trials, nor have they arranged for any independent trials, therefore the behavior of the steel in bulk supply is to some extent unknown. The following trials run on some tools made by the firm serve to indicate the results which may be expected. The test-piece on which the tools were operating was a chrome-nickel forging of the following composition:—Carbon, 0.32 per cent.; silicon, 0.07 per cent.; manganese, 0.59 per cent.; chromium, 1.26 per cent.; and nickel 3.28 per cent.

A 1 1/4 in. new alloy high-speed tool when used as a turning tool on the above forging at a surface speed of 120 ft. per minute; depth of cut, 3-32 in.; and feed, 1-32 in.; ran for 7 minutes before it broke down, while a tool made from a well-known brand of high-speed tool steel lasted, under the same conditions, for about 2 1/2 minutes.

A 1/2 in. square new alloy high-speed tool was run for some time with a feed of 1-32 in. and a surface speed of 55 ft. per minute; the speed was then increased to 112 ft. per minute, and later on to 120 ft. per minute. The tool stood this test satisfactorily, and was good for further service.

The new alloy tool used in the first test was ground up on the Gisholt grinder (dry), finished off on a wet gritstone, and then without any heat or other treatment was used in the lathe on turning the test forging with good results. The firm state that they will be putting the new alloy steel on the market in a few weeks.

Toolmaking Specialization.—In a paper read before the Keighley Association of Engineers, John Judson complained of the absence of specialization among the local tool makers. He pointed out that tool making was the basis of all other engineering manufactures. We needed more of the American readiness to scrap obsolete machines, and of the spirit of development. All the Keighley firms ought to get together for round-table talks, imitating in this respect the example set by Germany and America.

CONCRETE FOUNDATIONS

By A. L. Haas

BEFORE an engine or planing machine can be set to work or indeed any machine at all, it is obvious that some preparation of mother earth is necessary. The universal material for this purpose is concrete, which has the double advantage of low cost and durability added to which the material is worked in a plastic state and so can be made to assume almost any shape at will.

Ferro-concrete construction is the province of the specialist, but most engineers at some time or other need to utilize concrete and few understand the brief essentials of success. The local builder or handy man working by pure rule of thumb, does not as a rule prove successful, as witness the gaping cracks and poor work too often in evidence. Playing with concrete is quite a fascinating pastime to one versed in usual engineering materials, its plasticity and endurable nature are alike surprising to the metal worker. In the case of foundations which the average erector is called upon to deal with, there exists no sacrosanct mystery about the art which demands any considerable tuition.

Essentials of Concrete

Concrete consists of three dry essentials, aggregate, sand and cement, while the fourth ingredient is plain water. For the purpose indicated the aggregate should be clean gravel or broken stone. It should be uniform in size; this to some extent depends upon the size of the foundation from ¾ in. cube up to 2 in. cube, or a mixture of both in due proportions can be considered suitable. Sand should be clean, sharp when felt between the fingers, and washed to free it from small particles and any earthy matter. Cement should be of an approved brand artificially made, and from a manufacturer of repute. Water should be free from either acid or alkali.

Well made conrete consists of a packed mass of aggregate, the interstices between filled with sand, the voids between the grains of sand filled with cement. A film of cement, coating and separating the other materials and filling the minute voids between, forming the bond only.

Cement one part and sand two parts is the usual mixture adopted. To find the amount of this mortar with any local aggregate is easy. Fill a vessel of known capacity with aggregate (a 3-gal. bucket will do), pour in water from another can of known capacity until water is just level with aggregate. The quantity of water (volume) so found is the needed amount of 1.2 mixture. Taking a recent instance where 1½ gallons of water filled the voids, this represents 3 gallons aggregate and 1½ gallons of 1.2 mixture or 4 parts aggregate, 2 parts sand and 1 part cement. To be perfectly safe, 10 per cent. may be added to the sand cement mixture, and it must be remembered that the volume of the resultant concrete is that of the aggregate only. (There is a 5 per cent. increase which, however, may be neglected.) The figures are arrived at as follows:

6 parts aggregate, 3 parts mixture.
6 parts aggregate, 3 sand, 1½ cement.
12, 6, 3 = 4, 2, 1.

Results Desired

The object sought is least volume of cement for equal strength, increase in sand and cement does not add to strength, for this reason a little experimenting with the aggregate and a water can, will save the most expensive ingredient—cement.

Where say 2 in. and ½ in., or ¾ in. aggregates are to be used in combination, mixing these in varying proportions to see how they pack is worth while. It must always be remembered that complete filling of the voids in the larger material is the end sought.

Since the strength of the finished work depends entirely upon the due incorporation of ingredients, the quantities of each must be measured for each mixing. A simple square box, minus top or bottom, is at once the simplest and most effective method of gauging. Four level fillings with aggregate and then two of sand followed by one of cement gives the exact proportions. Having the area of the foundation and the thickness, the volume gives the amount of aggregate (invariably supplied by the cubic yard) while cement and sand in proportion need leave neither over plus nor insufficiency for the job.

The nature of the subsoil determines the thickness of the bed, where this is made land, it is always safe to double the erection plan instructions

The ingredients having been duly measured, the heap should then be thoroughly spade-mixed dry; twice turning is usual practice. The proportion of water needed is from 21 to 24 gallons per yard cube. The water (measured) is best applied with a rose-spout can, while the shovels turn the mass over.

The mass as soon as mixed is dumped in the excavation; rough board forms serve to contain it where the foundation is to be above floor level when finished. Tamping or ramming the wet mixture is desirable to ensure solidity and absence of voids in the finished job.

Regarding Reinforcement

Where the sub-soil is poor or where the foundation will be subject to heavy vibration, a reinforcement of plain steel bar at ¼ thickness from bottom (tension side) is advisable. Concrete is strong in compression and weak in tension; all reinforced work is designed with this in view. In the case of foundations of the character under discussion and made by the average erector, there is little danger of the reinforcement being too weak.

Another point not so well understood is that large fissures and cracks will not develop where rod is incorporated, the resultant cracking being then invisible to the naked eye. For this purpose the proportion of metal need only be small and expanded metal laid a few inches from surface obviates all danger from surface cracking.

Where a good exterior finish is needed the portions visible should be finished (rendered) for the last inch with a mixture of one-part sand, one-part cement worked to a surface with a wood float. This should be done subsequent to the placing of the job. The proportions of 1-1 gives a watertight coat, according to one leading authority.

Avoid Excessive Water

For the reason that the wettest concrete contracts the most, the least quantity of water to give a uniform plastic mass is to be desired. Temperature and weather conditions hasten or retard the setting and hardening of the concrete; frost indeed retards it almost entirely, and is liable to spoil the job.

As soon as the surface will not indent with the finger, it should be sprinkled and kept wet until the last moment. The chemical action which takes place does not cease for a long period, and depends upon an occasional drink.

Concrete strength increases with age, and does not attain its maximum for two years; it is about half strength at 28 days, so that the latter time should be allowed before mounting a heavy machine. If foundation plans are finished in advance, the time for setting does not usually result in serious delay. The difficulty as to the location of foundation bolts can be met by allowing square

chases for the bolts and filling these in when the job is at site.

Foundation Plans Inaccurate

It is a surprising fact, but none the less a true statement, that few foundation plans are accurate enough to locate holding down bolts in a concrete bed before arrival of job. Any outside erector of experience can corroborate the statement. Why this should be so is a mystery, seeing that bolt holes of this character are usually over-size.

The usual procedure, the foundation having already been prepared, is to level up the job on packing and then using a mixture of 1:1 cement and sand point in the entire under framing and bolts. The mixture should be rammed thoroughly in with board ends or sticks. Such a mixture sets quickly, especially seeing that it is of no great mass. This final grouting may also serve to permanently locate the job by bushing the mixture up to the top edge of bottom flange of framing.

It is frequently stated that the bed of a job should carry the weight of the superstructure without aid from exterior foundations. Until every maker adopts this counsel of perfection, it is certain that oil engines, compressors and most planing machines benefit from a due regard both to mass of foundation and the support rendered thereby. Even where the bed of the machine is heavy, the provision of a foundation platform is always desirable.

In the case of drop stamping plants, where the stresses are not self-contained in the framing of the plant, six or eight feet of concrete of adequate area serves to earn its keep by the absorption of the shock set up. Steam hammer foundations are another story; a resilient under-structure is needed to absorb the vibration; while the stresses are taken in the framing itself, the resiliency of the foundation minimizes the shock and renders the framing less liable to fracture.

Necessity for Re-alignment

Regarding planing machines and similar machine tools, where re-alignment from time to time is necessary, this can be provided in a variety of ways by folding wedge devices located in the concrete. At the same time, the stability of the machine and need for adjustment depend greatly upon the solidity afforded by the concrete underneath. It is thought that if due care were exercised both in the mass and composition of the concrete re-alignment, which gets scant attention in the average shop, would be less required and longer intervals might be left between such periodical attentions.

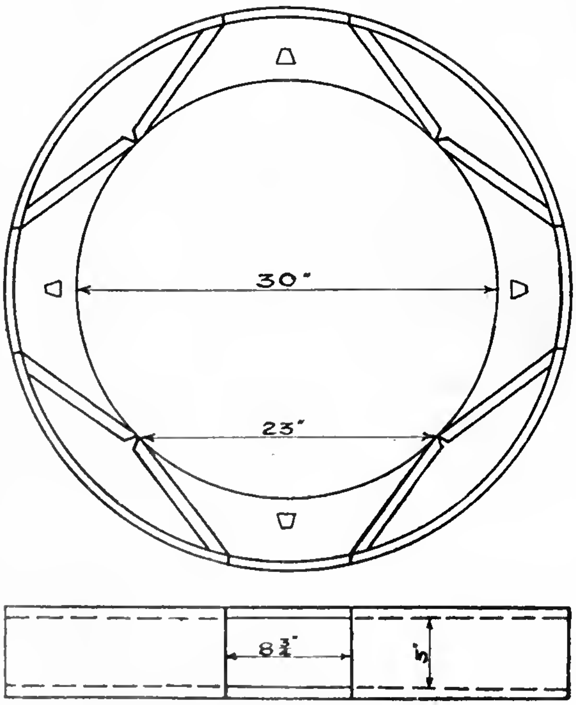
The facts in this article are in absolute agreement with the leading authorities on the subject, and none are disputed points. If this leads to better understanding and practice in the matter of laying concrete foundations, such as fall from time to time to the engineer and works manager, the purpose of the article will be served.

THE BOILER SHELL CUPOLA

By Jas. R. Tate

THE most successful cupola man I have yet worked with, was a man who loved his cupola. I fancy I hear and see him now. Never excited, always patient, and evidently knowing the cause of every little turn the iron took, during the heat. There was not anything peculiar about him, even his talking to the cupola. We all felt that it was the natural thing to hear John saying, "Steady, steady now," when the iron was coming rather quickly for us. Perhaps you have talked to your horse or your dog. What is there to the trooper who does not love and talk to his horse? What is there to the musician who does not love his instrument? It is a most natural condition. It is a true fingerpost to successful service, and one, without which, no man has ever been truly successful.

It is equally true with we foundrymen. We recognize the cupola as the very heart of our foundry, whether it be one with all the latest fads on it, or be just an old, homely-looking boiler shell affair, makes little difference. It is our cupola and of course we do not want anybody picking holes in it. Well, I am not going to find fault with yours at all. I know it is a good one or you would not have it. Why, of course not, but I am supposing that you just think so much of it that you would like to help the old friend a little. Help her to melt iron more easily and with less effort—help her to win more praise for herself as a good melter, etc.



THE BOILER SHELL CUPOLA

Taking this stand, we will figure it out as to whether or not you have been expecting too much from this old boiler shell cupola. In the first place. How much iron should you really expect to melt per heat? Conditions being right it is possible for you to melt "properly" about 9 lbs. of iron per hour, to every square inch there is in the area of your cupola; for instance, if your cupola is 30 in. diameter inside after bricking up, then it is possible to melt 6,354 lbs. of iron per hour, in such a cupola, providing other conditions are correct. The capacity of any cupola can be figured out in the same way as this one has been figured: Diameter of cupola 30 in. $30 \times 30 = 900$. $900 \times .7854 = 706$. $706 \times 9 = 6{,}354$ lbs. per hour.

Correct Amount of Air

Special attention must be given to the fan or blowers required, and tuyers—they are the main requirements and must be correctly proportioned to get the best results out of any cupola. There is more taking for granted, and hit and miss about the air that is required to melt properly, than anything else in a foundry. Giving our wives credit, on the side, I do believe they know more about the drafts in their cook stoves, than some of us know about the drafts in our cupolas—at least taking it turn for turn, good pies, poor pies, good heats, poor heats. It looks that way, only we are too conceited to admit it. But, after spending much money to find out, we have learned that there is a correct amount of air required to melt iron properly. To melt one ton of iron in one hour requires 30,000 cubic feet of air. So if your cupola has a capacity of three tons per hour, it would require 90,000 cubic feet of air to complete the combustion necessary to melt this amount of iron. The 30 in. cupola mentioned would require about 95,000 cubic feet of air per hour. Therefore, without going into further detail, get a catalogue of your fan or blower and see if it is big enough or too big, running too fast or too slow, to supply the air required to give your cupola a fair chance.

The next, and equally as important condition to consider is how to deliver this air. When you want to fill a pail with water from your garden hose, you do not turn the nozzle as you would do to throw the water on the roof. Why don't you? You simply want the water dropped into the pail. You don't want

it splashing around in every direction, do you? Well that is just what many of us are doing with our cupolas, only we are paying good and proper for it. We are delivering the air into the cupola under such a high pressure that it is cutting up all kinds of antics with the lining, the iron, the coke and the melting. Then we get ill-tempered and blame everything in sight and bang and hammer around hoping to hit something right somewhere, sometime. The fact is this, to melt successfully, the air must have room to get into the cupola, and all it wants to do is to get in there. It does not require forcing in at such a great rate. There is a rule which has been found to be correct. Taking this 30 in. cupola with an area of 706 square inches, the total amount of tuyer area must be one-quarter of this cupola's area, thus $706 \div 4 = 176\frac{1}{2}$, or in other words the total tuyer area should be 176 sq. in. If you are going to have 4 tuyers, then divide the 176 by 4 which gives 44 sq. in. to each tuyer. This would require an opening of about 5 x $8\frac{3}{4}$ at the small end of each tuyer, or at the end which is next to the shell.

The tuyers should now be widened out enough to make a complete tuyer running around the inside of the cupola. The circumference of a 30 in. cupola will be about 94 in. Dividing this up into four equal parts, will give $23\frac{1}{2}$ in., thus each tuyer iron will be 23 in. wide at the larger end and have an $8\frac{3}{4}$ opening at the smaller end. The tuyers of other size cupolas can be figured out by this same rule. If 5 tuyers are to be used, it is simply a matter of dividing up the quarter of the total cupola area into 5 parts, as we have here divided it for a 4-tuyer cupola.

Locating Tuyers Vertically

In cut you will notice there are posts set into tuyers. Their only duty is to stop coke from pushing into the tuyers. Under the mentioned conditions, a cupola will be supplied with oxygen in volume and not under pressure, giving in return perfect combustion and good iron.

As for the height tuyers should be from sand bottom, that is a matter controlled by the nature of your work. Certainly the lower the tuyers are placed, the less coke is used up in building a bed, which must reach the melting zone. For the ordinary jobbing shops, 12 in. from the sand bed to the lower edge of tuyers, I have found to be the most serviceable, but should your work be of a light nature, 9 in. is plenty. It will save you much coke and give you just as good iron as would be given with the tuyers 19 in. from bed.

I do not like the word "blast" in cupola practice, it is misleading. We do not want a blast, we want the air, and what the air contains. Many and varied are the methods of conducting air from fan to cupola, but with this variation I have learned, that to cause friction, by having small pipes, many elbows and sharp turns, is detrimental to the melting qualities of any cupola. In fact the only way to give your fan and cupola a fair chance, is to have the air pipe larger than the opening at the fan. Have it two inches larger in diameter at least, and do away with as many elbows as possible. I use the words air-pipe. I hope you will think of it as such. You don't want air squirted into you under pressure, do you? Well, the cupola is just as human as you are in that respect. It just wants the oxygen in volume, but not to be crammed full like a ballon.

Provide Gates on the Air Pipe

Gates on the air pipes are good things and pay for themselves in a short time. It will naturally take less air to melt the iron at the latter part of the heat, and with a little practice, the use of these gates will become an important part of your cupola practice. It is also essential that these gates should be on the air pipes, for we often hear of an explosion having occurred in some foundry, caused by gas backing up into the air pipes when the fan was stopped. With the gates it is an easy matter to close them, and thus avoid such an accident, at such times as the fan is stopped during a heat.

The height of charging is often governed by the style of building the cupola is placed in. This is, in some cases, apparently justifiable, but if we are to get the very best out of every dollar we spend in our foundry, it will pay us to have this part as near right as some of the other more active portions. Taking this 30 in. cupola again, suppose the charging door is 60 in. from bed plate, our tuyers are 12 in. above bed, causing the melting zone to be about 30 in. above the bed plate. Here we have only 30 in. left for charging. Does it not seem reasonable that the iron last charged in this cupola, will reach the melting zone at a cooler temperature, than a cupola of the same proportions, charged to the door which is 120 in. above the bed plate? The point is, that we are getting more value out of the coke burned in the latter cupola, and are helping the cupola to melt iron more easily and quickly by depositing the iron in the melting zone heated to a higher temperature. Certainly, in the large sized cupolas this is hardly practical, as the height would be too great, but in the smaller sizes, say up to 54 in. cupola, it is well to keep the charging door three or four times as high, from the bed plate as the cupola is in diameter.

INCREASED PRODUCTION BY CO-OPERATIVE EFFORT

By J. R. Hamilton.

WITH the demand for increased production, particularly for a short period, it is customary to operate the plant for a sufficient number of hours "overtime," by the ordinary day staff. This method, however, of increasing the output, while fairly successful temporarily, has been found unsatisfactory if extended unduly. The workmen, in anticipation of receiving a little extra remuneration, will for the first few nights or so be quite able to meet the extra demand made upon their normal store of energy, but as time goes on, the apparent novelty of the thing begins to wear off. They become weak and languid from the long hours, lack of interest and enthusiasm develops, and in many instances men will be found at work during the "overtime" hours and be missing altogether on one or two mornings each week. Under the above conditions production will increase only while the men are still physically fit. It will therefore, be found that very little is to be gained by having them continuously at work for fifteen or eighteen hours a day after the first week or two.

Two and Three-Shift Systems

When the demand for product reaches the stage that longer plant operation becomes absolutely necessary—for example the manufacture of shells — then no other course seems open but the organization of a night shift. During the initial stages of the present shell-making activity, many factories tried out the extra or overtime system, but increasing demands made it imperative that the machine equipment be kept operating at full capacity for almost the entire 24 hours per day. While the system in vogue in many of the large shell forging plants is that of operating three shifts of eight hours each; the general practice adopted in the machining of the shells is to have two shifts only, one during the day and the other at night. To successfully accomplish this, however, requires careful and tactful consideration on the part of the plant superintendent and shop foremen. It is advisable to secure sufficient first-class workmen for the night shift to maintain an even balance with those operating the same machines during the day, but it is often exceedingly difficult to obtain and hold good men for night work. Skilled workmen, capable of holding responsible positions, prefer to work in the day, and unless some concessions are made for night work, the possibilities are that the night staff as a whole—will be inferior to that employed during the day.

Many disadvantages arise from working at night. Loss of regular sleep: improper nourishment: insufficient and

improper shop lighting; all help to break down the constitution of the average workman. However, in times like the present, when everyone is working at high tension, these, as well as many other objections, pass into the background to make room for the one essential factor—the production of shells to the full capacity of the plant and also every individual workman.

Day and Night Operator Traits

Two of the chief factors entering into the ultimate output of a certain machine, operating day and night, are the individual traits and working methods of the day and night operator. In a great number of cases these two men never see each other, with the result that little co-operation takes place between them. When one stops to consider that there are all classes of men operating shell machinery, the range of mechanical ability between two workmen may, and very often does, vary to a marked degree. I was told by an operator, a short time ago, that he spent from thirty minutes to an hour every morning, sharpening tools and putting things in shape before he could get started. He said he could not see how the night man did the work with such tools. One might say that this particular man was a little fussy, or had an exaggerated opinion of his own ability; but the fact remains that his record was about ten per cent. higher than that of the night operator for the same period of time.

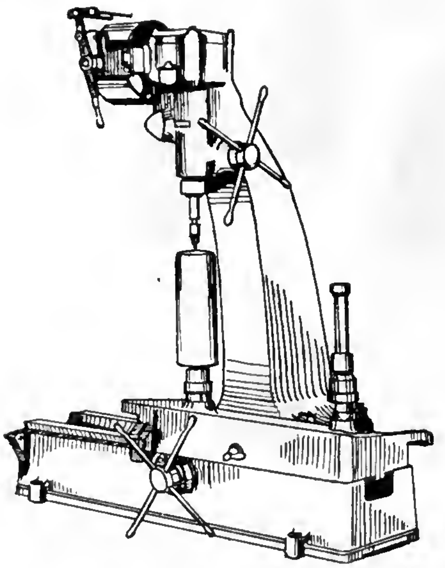
In direct contrast to this case was another in the same shop, where two brothers were operating the same machine, one during the day and the other at night. It appears that these two brothers had made a careful study of all the details of operation; handling of the work, sharpening and setting of the tools, special location for all auxiliary equipment, etc., so that, as each one came to his work at night or in the morning he was familiar with conditions prevailing during the previous shift. Each one advised the other of any developments during his period; such as, the particular nature of the steel being worked, breakages or replacing of cutting tools, transmission troubles, etc., in fact each man was so informed that it was as if either was operating the machine continuously. As a result the output from this one machine was greater than that of any other, working on a similar operation.

From this it would appear that to operate machinery day and night, it is quite advisable to have some understanding between the men of each shift, so that by mutual co-operation, and adjustment of individual ability, petty barriers of personal prejudice may be broken down, and a force created that cannot fail to achieve remarkable results.

SHELL-CENTERING MACHINE

THE accompanying sketch shows a shell-centering machine as supplied to British munition makers by William Asquith , Ltd., Halifax, Yorkshire. The essential features of the machine are of the simplest possible description, no superfluous detail having received any consideration whatever. The sliding work table is gibbed to ways on the top of the bed, and is provided with two vertical work arbors carrying suitably arranged conical bushings which automatically centre the shell forging.

By means of the cross-handle in front operating a rack and pinion, the table is moved to either side so as to bring each arbor alternately under the spindle. Stops are provided for accurately adjusting the position of the arbors. The spindle has a down feed of 4 in. through cross-handle at side, its speed being 480 revs. per min. It runs in ball bearings, and has a ball thrust bearing for the thrust.



CENTERING MACHINE FOR LARGE SHELLS.

Tight and loose pulleys are mounted on the upper part of the column, dispensing with a countershaft and keeping the belt clear of all possible contact with the operator. A special scribing attachment can be fitted to indicate whether the forging is within the limits of concentricity required for machining purposes.

THROUGH BILLS OF LADING

THE term "through bill of lading," means a bill of lading from the port of shipment to destination. It may happen however, that unless a sufficient quantity of freight is offered for some of the less important places, a "through bill of lading" will not be issued by every sailing. The steamship companies can usually advise in such cases, whether it is desirable to ship to the nearest point for which a "through bill of lading" is issued or as to the probable date when shipment can be made direct on a "through bill of lading" to destination.

ALTERNATING CURRENT DRIVING IN FACTORIES

INFORMATION of value to those who contemplate driving workshops with alternating-current motors was given in a paper read before the Junior Institution of Engineers by G. H. Ayres. As regards the electrical operation of cranes, it was pointed out that there are three types of motors that may be used, direct-current series motors, alternating-current slip-ring motors, and alternating-current squirrel-cage motors. The direct-current series machine is undoubtedly the best for crane driving, but its use is, of course, prohibited where the supply is an alternating one. The next best machine is the slip-ring motor. In the opinion of the author, however, the squirrel-cage machine will, if properly designed, answer the purpose quite well, and offers the advantage that only half the number of trolley wires required by a slipping motor are needed, which arises from the fact that no separate control is necessary for the rotor circuit.

Under the heading of fans, Mr. Ayres said that from the efficiency point of view, the slip-ring motor appears at first sight unfavorably at reduced speeds, but as the output of a fan varies directly as the cube of the speed, it will be found on plotting a curve showing the relation of speed to energy dissipated in the rotor, to reduce the speed, that the wastage is not so formidable as it seems. Large machine tools, it is pointed out, occasionally call for speed variation.

The author considers that in these cases it is usually advisable to employ a squirrel-cage constant-speed motor, and to drive through a countershaft by means of stepped pulleys or else by some form of gradual-change speed gear, such as Reeves' gear. Slip-ring motors with resistance in the rotor circuit are quite unsuitable on account of the poor speed regulation, the speed varying appreciably with every change of torque. Suppose, says the author, in a large lathe or planing machine, that a cut is being taken over a broken surface, such as the underside of a bed-plate, and the controller is set to give half speed with full-load torque, then between the cuts the motor will speed up considerably and the tool will strike the metal on the next portion of the cut at a damaging speed.

Multi-Speed Motors

Where a change-speed countershaft is impracticable, a special multi-speed motor designed for pole-changing may be employed. Suppose two speeds are required, with a ratio of 2 to 1. The stator would be wound with a single winding as in a normal machine, but arranged so

that by means of a simple throw-over switch the number of poles is altered and high and low speeds obtained as required. Such motors can be made for the same output at both speeds or to give at the top speed twice or three times the output given at the low speed. As regards cost, however, this machine would naturally be rather expensive. When two speeds are required with a ratio other than 2 to 1, or if four speeds are required, the motor must have two separate stator windings. The majority of multi-speed motors are constructed as squirrel-cage machines, but it is possible to build them with wound rotors.

Accumulator Controlled Pump Drives

These multi-speed motors are ideal for driving hydraulic pumps. The speed changes are made by a controller operated by the travel of the accumulator, and the switching arrangements are considerably cheaper than is the case where direct current motors are used. An interesting example of such an installation is to be found in a large railway works. Three motors are designed to give synchronous speeds of 333, 500 and 1,000 revolutions per minute respectively, with corresponding outputs of 30, 45 and 90 horse-power. Each motor has two stator windings—one for 18 poles and one for 12 poles—and by reversing half the latter winding a 6-pole field is produced.

Under the heading of peak loads come power presses, punching and shearing machines, and other similar machines, which usually do heavy work during only a small portion of the operating cycle. Most machines of this kind are fitted with fly-wheels to overcome the peak load. There are two possibilities which make the fly-wheel of little or no value. Either the capacity of the motor may of itself be insufficient to overcome the peak or the characteristics of the motor such that there is insufficient drop in speed to permit the fly-wheel to give up the energy stored in it, which is apt to throw considerable overload on the motor.

When the greater part of a workshop is driven from line shafting and the machines are provided with fast and loose pulleys, the adoption of alternating current in a factory having its own plant is very convenient and economical, as a squirrel-cage motor can be left permanently connected to the generator and will run up to speed with the generator without taking excessive current. An exciter rather larger than usual is necessary, but the method of starting is, in the opinion of the author, an excellent one. When single-phase current is supplied to a factory the Arno-Ferraris starting system is advocated.

The Generating Plant

The generating plant should consist of two steam turbine-driven alternators, each having a capacity of two-thirds of the aggregate horse-power of the works motor equipment. Normally one of the sets stands idle, but may be used to take up load and help the other set when the works are busy. The turbines, generators and switchboard should be erected on the ground floor and the condenser in the basement. Also, there would be mounted in the basement a high-speed vertical steam engine, connected through a clutch to the air and circulating pumps. These would also be coupled to a three-phase squirrel-cage motor, so that they could be run from the main generator supply. This motor should be of sufficient capacity to drive the pumps at one end of the shaft and the exciter at the other end, the exciter being of sufficient capacity to deal with the lighting when worked by the engine at times when the main sets are shut down. The method of starting up the plant would be as follows:

First the small engine is started with the clutch in, so as to drive the pumps and exciter. The vacuum and exciter volts are so obtained. Next the turbine would be run up to speed, and as voltage and periodicity increase, the main line shaft moters in the works run up to speed simultaneously. Full voltage having been obtained, the pump motor would be switched into circuit and the engine de-clutched and shut down.

Departmental Arrangements

Most machines in pattern shops must stand well into the middle of the space available on account of the size of the pieces of wood to be passed through them, and, further, on account of the fact that the patternmakers' benches are placed round the walls under the direct window light. As the motors, usually ranging from 5 to 25 horse-power, and start light, squirrel-cage machines with star-delta starters may be used. A duct should be placed under the floor, to extend from side to side of the room and open to the atmosphere outside the building. Pipe-ventilated motors drawing air from this duct and discharging the air through gauze into the room are the most suitable for pattern shops.

In the foundry a short length of shafting can be used for driving rumblers, grinders, saws, and the sand blast. This length of shafting may be driven by an open protected-type squirrel-cage motor started with the turbo-generators. As the atmosphere of a foundry is charged with dust, this motor must be cleaned by blowing it with a pair of bellows at least once a week. Cupola blowers should be driven by slip-ring motors, with a regulating resistance in the rotor circuit.

An economical arrangement for machine shops is to have two large main bays separated by a narrower small bay. On the division stanchions between each large bay and the small bay would be a line shaft, making possible the provision of four lines of machines—lathes, capstans, turrets and millers. On the outer side of the main bays would be the large lathes, planers, etc., requiring individual drives. The line shafting would be split up into lengths, requiring motors of from 30 to 50 horse-power. It should be possible to couple or isolate these lengths of shafting by means of clutches. The motors should be close to the shafting and should drive through silent chains running in oil baths. As the motors start up with the turbines only emergency starters will be required, and the handles of these starters should be fixed in the "on" position by means of padlocks. Above the small bay would be a gallery for light machines or for the assembly of detail work.

Various Practical Application

Blowers and exhausters in the smiths' shop may be driven by high-speed squirrel-cage motors with star-delta starters. Drop hammers, shears, and angle choppers may be driven by high slip squirrel-cage motors and a simple switch; coupling the stator windings directly to the mains will suffice, the torque being ample to accelerate the fly-wheel in reasonable time. Cranes erected over main and small machine bays and also in foundries may be driven by squirrel-cage motors with high-resistance rotors. There should not, however, be any mechanical or soldered contacts in the rotor circuits. All joints must be welded or cast solid. Tramway type reversing controllers may be used for inserting and cutting out resistance in slip-ring rotor circuits, and the longitudinal and cross traverse controllers should be geared together and operated from one handle, so that the movement of the controlling handle is in the direction of the motion required.

The author assumes that the plant is laid out in accordance with the modern plan of receiving goods at one end and shipping them at the other end of the main aisles. Under these conditions there will be in the receiving stores a capstan for wagon haulage, and this capstan will be worked by a two-speed squirrel-cage motor. The controller would consist of two pedals giving high and low speeds and having a spring return arrangement for returning the controller to the "off" position.

Hydraulic lifts, presses, etc., would be supplied by three-throw pumps and an accumulator, and the pumps would be driven by multi-speed motors, as already described. The advantage of the multi-speed motor over the stop-and-start system is that it runs for longer periods at one speed, and thus saves the continual breaking of the circuit. The compressor for supplying compressed air to pneumatic tools and for brazing and soldering must, on account of the heavy torque needed, be driven by a slip-ring motor.

Canadian Manufacturers' Association Convention

The accompanying abstract of the proceedings of the recent Canadian Manufacturers' Association Convention will serve to indicate that those responsible for the adminstration of our varied industrial enterprises are fully alive to the pressing needs of the hour as well as to committment without delay to a scheme of co-operative effort which will enable them to meet successfully post-bellum trade conditions as far as these can at the moment be anticipated.

THE 42nd annual convention of the Canadian Manufacturers' Association opened in the Royal Connaught Hotel Hamilton,, Ont., on June 13, and occupied three days. The unusual conditions prevailing in the Dominion, owing to the war and the general effect on business, lent additional interest to this year's meeting. The proceedings were opened with the reading of the annual report by the secretary, G. M. Murray. The report showed that the association had accumulated a surplus of $4,922.50 during the year, and had now a reserve of $50,168.49. Reference was made to the depletion of the staff owing to the war. Col. Poussette, the Western secretary, went overseas with the second contingent; Capt. McIntosh, the Toronto secretary, enlisted with the 70th Battalion; Major Stirrett, editor of Industrial Canada, was with the 126th Battalion; Mr. Meldrum, the Montreal secretary, was taken by the war department of the C. P. R. and sent to London; his successor, Mr. Campbell, is now in France with the Trade Commission; Mr. Scully also left for military service.

President's Address.

President J. H. Sherrard, in his address, reviewed the military situation and the events in the economic field in Canada during the past year. He spoke of the splendid response of farmers and manufacturers to the call for increased production and its effect upon the prosperity of the country. "Our farmers are prosperous," he said; "our workmen are profitably employed; our mills are busy." The making of munitions, said Mr. Sherrard, had not only brought a considerable degree of prosperity to Canada, but it had also improved the efficiency of workmen and manufacturers, and advertised Canada as a country capable of producing something besides wheat, apples and lumber.

Registration

He alluded to the difficulty manufacturers and farmers alike were now experiencing in securing labor, a situation in striking contrast to that of a year or so ago, when manufacturers were devising means to find work for the unemployed. He pointed out that while it was essential that Canada should furnish soldiers to defeat the enemy, it was equally essential that she should feed and clothe them and supply them with ammunition.

In England, where the women had rendered splendid service by taking the places of men, conscription had been found necessary in order that every man's service could become effective. Therefore, he asked, "has the time not come for Canada to register her men, so that those who can be most useful to the war by remaining at the work they are necessary to shall not be recruited, and so that the remaining available men will be induced to do their duty by enlisting? We have already lost much ground that we might have occupied because we have refused to even whisper conscription. Can we longer afford to drift along with closed eyes?"

Trade After the War

Next to the prosecution of the war, continued Mr. Sherrard, the question of trade after the war was perhaps the most important subject which could engage the people of the allied nations. It was known that the warehouses of Germany were bulging with manufactured goods accumulated during the war for the purpose of again flooding the world's markets. The Allies were now studying how they could protect their markets from the threatened invasion and develop trade with one another. Great Britain was also studying how she could develop inter-Empire trade, and there were indications that she would abandon the principle of free trade. Would she, however, give her Overseas Dominions a preference on foodstuffs and would she require concessions in return?

President Sherrard pointed out that Canada had long granted British manufactured goods a tariff preference in her markets. He argued that a preference for Canadian foodstuffs in the British market would not increase the cost of the loaf there and would be of great benefit to the Dominion. He insisted that Canada should be wise enough to prepare now for the time when orders for munitions and war supplies would be cut off.

Industrial Mobilization

"We must mobilize our industrial forces to show the other portions of the Empire and the allied countries what we produce," said Mr. Sherrard, "and we must prosecute a vigorous trade campaign in all these markets. For this we will need the co-operation of our transportation companies and our banks. We will need the assistance of our Government in securing information regarding markets and their needs; in providing technical education; in assisting scientific research.

"This is an opportune time for our Government to place the tariff on a scientific basis and beyond the influence of politics. This is an opportune time for our Government to urge trade agreements with the Empire and with our Allies, and to pave the way for Canada's entry into world trade."

Membership Declines

The report of the Membership Committee showed a decline in the twelve months of 78, leaving the total membership now at 2,983. The net loss in revenue was $1,055. Owing however, to the scaling up to higher classes of some members, the loss in potential revenue was only $300. H. P. Hubbard, who presented the report, advocated increasing the membership. The report was accepted.

Hon. Col. Thomas Cantley, vice-president, delivered an interesting address on "The Development of a Canadian Shipbuilding Industry," publication of which will be made in our June 29 issue.

Workmen's Compensation

Regarding the Workmen's Compensation Act, it was suggested in a special report of the Legislation Committee that pressure be brought to bear upon the Government for the adoption of the current cost instead of the capitalized plan. About $1,500,000 had been taken out of the industries of Ontario for this Act, while only $325,000 was needed. The Act did not make any provision for first aid or medical attention, and the Act should be amended to this extent. A benefit fund in factories by which workmen would contribute to this east was suggested. Mr. Shaw, in presenting the report claimed that Hon. I. B. Lucas or Hon. W. J. Hanna had intimated to a delegation of the C. M. A. that the Government would defray the cost of the administration of the Act, but that this was not done.

The report on the insurance tax criticizing same adversely was adopted.

Developing Export Trade

At the opening of the session on Wednesday a strong plea for a united effort to increase Canada's export trade after the war, especially to countries now allied with Great Britain in the struggle with Germany, was made by R. J. Younge. Mr. Younge is manager of the

Export Association of Canada, an organization which was formed after the discussion of Canada's exports at the meeting of the association last year, and which has done good work already in laying before the world Canada's abilities as a manufacturing country. Mr. Younge appealed for the hearty support of those present.

"If Canada is to make itself known as an industrial country it is its duty to tell the Allies what she is manufacturing," he declared. "It is all very well to say that Canada has responded to the calls which have been made upon her. She has done so, it is true. She has helped the Empire magnificently; but what of ourselves? The manufacturers are not responding to the appeal to unite in making known what we can do in the way of manufacturing. Only 104 out of some 19,000 or 20,000 manufacturers have put their hands into their pockets to help the movement. If you think the movement is worth while, show it. We have learned that there are opportunities of supplying goods, of keeping the working people employed and of making dividends. Let us have more results.

In connection with the report on Trade Development, W. H. Banfield, of Toronto, pointed out the serious problem which after the war would face many manufacturers who had installed costly machinery for the making of munitions. He also told of some of the troubles of a munitions manufacturer.

Co-ordination of Resources

A note of national importance was struck by Dr. J. C. McLennan, Professor of Physics at the University of Toronto, and president of the Royal Canadian Institute. Dr. McLennan suggested that a commission be appointed by the Government which would co-ordinate resources of the Canadian Manufacturers and cooperate with Canadian Universities towards furthering industrial research .

"There are buildings belonging to the Universities in British Columbia, Manitoba and other provinces, lying vacant," declared the speaker. "Millions of dollars are invested in plant and equipment by the University of Toronto with only two or three men working in them. There is more money invested in the universities of the country than in the railroads."

As showing the value of research, the speaker pointed to the General Electric Co., of Schenectady, U.S.A., which paid out $200,000 per year to experts employed in such laboratories. The larger proportion of the experts employed in those laboratories are Canadians," he declared amid applause. "Why do they leave Canada? Because they can get $1,200 or $1,500 a year, which, apparently, they cannot get here. We are steadily feeding the United States with our brightest and best young men."

The closing session was held on Thursday on the steamer Chippewa on the return trip from an outing to Niagara Camp. Motions were passed along lines previously discussed, which dealt directly with the most momentous problems facing Canada to-day. Among these were resolutions calling for the co-ordination of recruiting and production, and for the extension of industrial research work in the universities. One dealt with the best methods of defeating Germany on the field of battle, while the other aimed at the surest way of meeting her in the industrial war which is certain to be waged upon the conclusion of the present hostitities.

Election of Officers

The officers elected were as follows:—President, Col. Thos. Cantley, New Glasgow, N.S.; 1st vice-president, S. R. Parsons, Toronto; 2nd vice-president, W. J. Bulman, Winnipeg; treasurer, Geo. Booth, Toronto.

Executive Council—Messrs. W. K. McNaught, J. F. Ellis, P. W. Ellis, W. K. George, R. S. Gourlay, Toronto; C. A. Birge, R. Hobson, Hamilton; C. C. Ballantyne, Montreal; H. Cockshutt, Brantford, John Hendry, Vancouver.

Resources Mobilization

As suggested by the Special Committee dealing with the question, a strong resolution was passed calling upon the Government to mobilize all the resources of the country, both of men and material. This resolution, which was enthusiastically adopted, reads as follows:

"Resolved that the Canadian Manufacturers' Association express to the Government of the Dominion of Canada its firm conviction that fighting for one's country is the supreme duty cast upon all men in time of war, and that furthermore the burden of such service should be borne equally by all properly qualified men of the nation. The association also expresses its approval of any scheme, whether under the Militia Act or the Defence of the Realm Act, or otherwise, for the complete and effectual mobilization of the entire resources of Canada in men and material, and is of opinion that these should be placed unreservedly at the disposal of our country."

Inter-Empire Trade

Dealing with the question of tariffs, the association went on record as "favoring an arrangement that will give first care to the development of inter-Imperial trade by means of preferential tariffs: that will next give practical encouragement to the trade of our Allies: that will thirdly give us the protection of our general tariff against neutral countries: and that will lastly place the products of enemy countries under such fiscal and other disabilities as will effectually restrict their sale in our markets."

The association also expressed itself as in favor of the removal of the excise duty on alcohol used for manufacturing processes, scientific and medicinal purposes.

Closing Functions

The convention concluded with a banquet at the Royal Connaught Hotel, the guest of honor being Sir Thomas White, Minister of Finance. Hon. F. W. Crothers, Minister of Labor, and Lionel Curtis, Secretary of the Round Table Movement, England, were also present as guests. The new president, Col. Thos. Cantley, was in the chair and acted as toastmaster.

Mr. Cantley dealt at some length with the matters discussed during the sessions of the convention. Canada must awake to the possibilities which were knocking at her door as a result of the war. She must seek in every possible way to increase her trade so as to be better able to meet her share of the expense of the war. New lines of activities were opening up before the manufacturers. No one could say definitely what lay in the future, but Canada must be prepared to meet changed conditions and profit by them.

Col. Cantley believed that the time was ripe for the establishment of an active shipbuilding industry in Canada, greater than any other on the continent. He looked for assistance from the Government to bring this desired result about.

Sir Thomas White, who had inspected the munition plants of the city during the day, was deeply impressed with what he had seen of the enterprise of those in charge. He paid especial tribute to the Steel Company of Canada, whose cooperation during these strenuous times was most commendable.

Where soft castings are wanted, the rate of cooling has very much to do with the matter. Assuming that the silicon and carbon content are properly proportioned, slow cooling gives the desired results owing to the fact that the carbon very largely separates as graphite carbon. To secure the best results the sand should be used as dry as is possible to produce a good mould, and there should be a good body of sand of a porous character to back up that forming the actual mould. There is an advantage also in facing the moulds with plumbago, or very finely ground charcoal. This prevents the formation of a siliceous skin on the casting, although the carbonaceous coating to the mould is practically a mere film. Allowed to become practically cold in such moulds, castings should be as soft as the character of the iron will permit. Cast iron is not appreciably amenable to annealing after it has cooled, but during solidification and cooling down to about 300 degs. C., the rate of cooling exerts much influence.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

MILLER FOR 6-IN. H. E. SHELL BASE PLATES

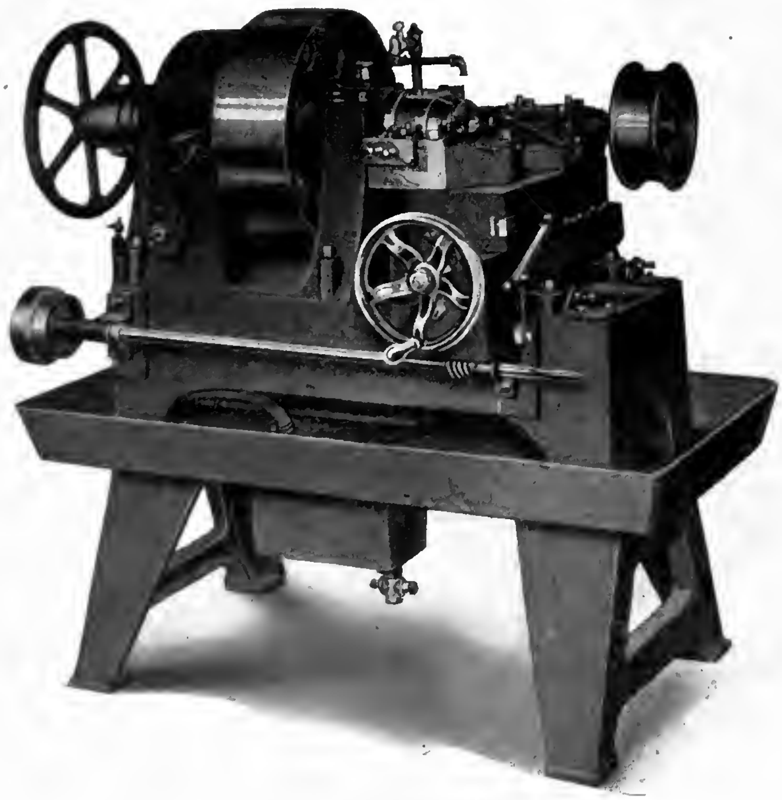
A MACHINE for milling base plates or plugs for 6-in. high explosive shells is being built by Edwin J. Banfield, Toronto. The machine is similar in many respects to the miller put on the market by Mr. Banfield some time ago for milling plugs for 18-pdr., 4.5-in., and 60-pdr. high explosive shells. It is, however, of heavier construction throughout, and can also be tooled up for machining bevelled plugs, which is an alternative proposition to the threaded plugs. The former type of plug has been adopted by many munition concerns, and the one machine can thus be used for machining either type of plug.

Detail and Operation Features

The machine has a 3⅞-in. diam. hollow shaft, driven by an 18 in. x 6 in. pulley direct from the line shaft, and the capacity is ten 6-in. threaded plugs per hour. As in the original machine, the plugs are held in a collet chuck with a drawback mechanism operated by a hand wheel. A double jaw clutch is mounted on the shaft, and so arranged that in the first position it engages the main pulley with the spindle for machining the plug, and in the second position, the shaft is revolved by a bronze worm and gear driven from an independent pulley at the back of the machine. The latter drive is used when milling the plug.

The front tool holder and milling attachment at the back are secured to the cross slide mounted on the carriage, which can be adjusted so that any required camber can be obtained. There is a micrometer adjustment in connection with the spindle operating the cross slide. The micrometer reads in thousandths and permits of great accuracy when setting up the tools to the fixed stops. The milling attachment has an independent drive and consists of a spindle carrying a standard cutter revolving in a sliding bearing bracket attached to the cross slide. Extending from the bracket is an arm carrying a chaser which engages with the threads on the outside of the collet chuck.

The tool for rough turning the outside diameter of the plug is fixed to the cross slide and under the work. When this operation is completed the cross slide is moved inwards and the first tool in the front tool holder roughs the face of the plug. This is followed by a similar tool, which finishes the face. The tool holder continues to travel inwards and another tool faces the back of the plug for a short distance, leaving a clean surface for riveting. Another tool chamfers the front edge.



MILLER FOR 6 IN. HIGH EXPLOSIVE SHELLS.

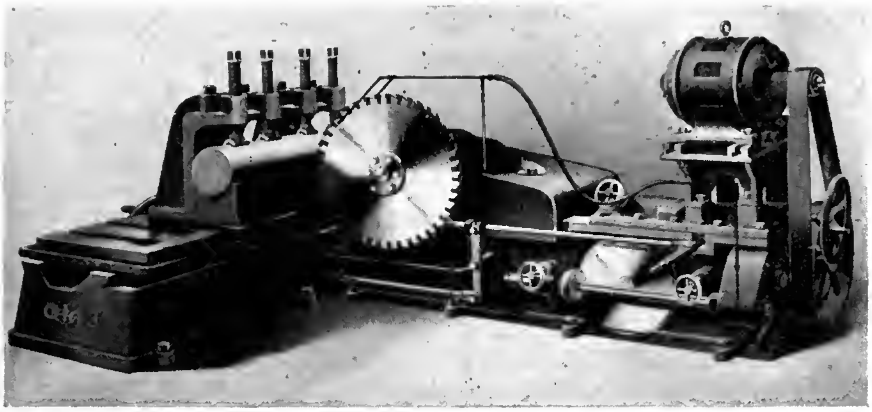
The next operation consists of milling the threads on the outside diameter of the plug, which is performed by the attachment on the cross slide at the back. The milling cutter is brought up against the plug and a dog slipped into position, which ensures the chaser nut engaging with the threads on the collet chuck. The clutch on the main spindle is then thrown back, bringing the worm drive, which has a ratio of 100 to 1, into gear and giving the slow motion necessary for milling the threads. The attachment is fitted with a hand lever for returning the cutter to its original position at the end of the cut. The feed shaft used during the initial operations is located in front of the bed and is driven by a 2-step cone pulley, giving two feeds to suit soft or hard plugs. A trip at the side throws the feed out at the end of the operation. The machine is equipped with a rotary pump having an automatic relief valve for controlling the flow of the cutting compound to the tool. All bushings have hard bearing metal.

Beveled Plug Production

For producing the beveled plugs, the machine is identically the same as described above, with the exception of the tooling fixtures. The milling attachment at the back is not required, and in its place is mounted on the cross slide at the back a tool holder with a tool for rough turning the back of plug. The first operation consists of rough turning the outside diameter and the bevel, which is performed by a set of cutters located on the cross slide immediately under the work. The back tool holder is then brought forward for rough turning the back of the plug. On the front tool post which is mounted on the cross slide are located four tools set in a way similar to the fixture described above. The first or forward tool roughs the face of the plug, which is followed by a second tool set just behind for making the finishing cut. The third or forming tool finishes the outside diameter and the bevel, while the fourth tool finishes the back of the plug for a distance of ⅜ in. to ½ in. Enough metal is left on so that the plugs when in the shell project any required distance above the level of the base.

COLD METAL SAWING MACHINE

THE accompanying photograph shows a high duty type of Q.M.S. cold metal sawing machine which has been placed on the market by the Vulcan Engineering Sales Co., Chicago. The machine is designed to drive inserted tooth saw blades to their maximum capacity and embodies numerous features tending toward convenience of handling and efficient operation.



COLD METAL SAWING MACHINE WITH FRICTION FEED AND CENTRALIZED CONTROL.

The saw is mounted on a flange forged on the end of the saw arbor, which is provided with two cut gears forged integrally with the arbor, the teeth of each gear being cut opposite the spaces of the other. These gears are driven by solid forged pinions cut on the worm wheel shaft in a staggered manner to match the gears, the resultant drive being characterized by an absence of back lash reducing the chatter of the saw blade to a minimum.

The illustration shows the machine with motor belt drive, the power being transmitted by spur gearing inside the bed to a splined shaft, which extends along the back of the bed, and drives the main worm and worm wheel. The former is of hardened steel and large diameter, provided with roller thrust bearings, and the latter is of two-piece construction consisting of a steel centre and special bronze rim. They are completely enclosed and run in grease.

The saw carriage is of box section construction and scraped to fit the shears of the main bed. It has full length bearing taper gibs to compensate for wear, hand adjustment, automatic stop and quick power return. Change of feed is obtained by a combination of friction disc and gears which provide a range of from 5-16 in. to 2½ in. feed per minute, the friction wheel being so arranged that it automatically sustains the proper contact with the friction disc. Two changes of peripheral or cutting speed are provided, either 30 and 50 ft. per minute, or 40 and 60 ft. per minute.

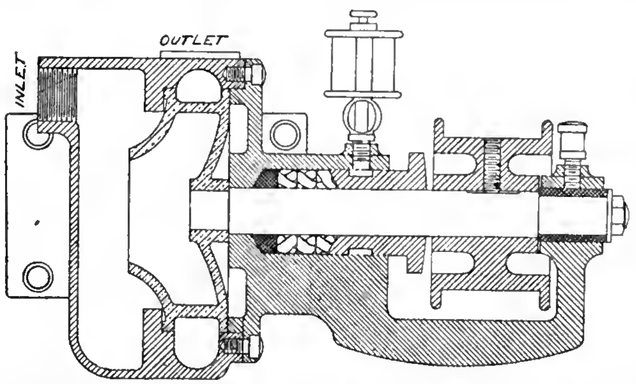
Levers and hand wheels controlling feeds, cutting speeds, and return movement are conveniently grouped together, the lever for engagement of feed and quick power return being extended to the front of machine as well. All gears run in oil, and internal bearings are lubricated by oil pipes leading to the exterior of the machine.

The work table is provided with tee slots, which enable the holding clamps to be adjusted as required. It is gibbed to ways on the top of cross bed, and has an oil trough cast completely around it. Lateral adjustment is obtained by rack and pinion operated by hand wheel on outer side of work table.

GRINDER LUBRICANT PUMP

A SPECIAL type of Fulflo centrifugal lubricant pump has been placed on the market by the Cincinnati Lubricant Pump Co., Cincinnati, which has been specially designed for use on grinding machines. In external appearance it is similar to the regular design of this pump, although the geared drive to impellor shaft has been altered to a direct pulley, on the outer side of which a bearing is provided, supported by an arm from the pump body.

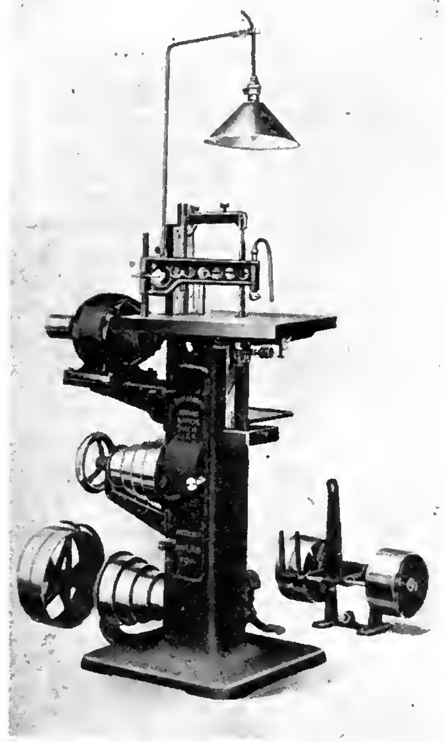
Owing to the high location of the inlet, the trap effect obtained dispenses with the necessity for priming and allows of the pump being mounted above the level of the liquid. The inner bearing is formed by the stuffing box gland, which is of cast iron, and is protected from the emery grit and dirt by a combination of metallic, graphite, rubber and flax packing. With a suction lift of 12 in. and a delivery head of 4 ft. the capacity of the pump at various speeds is as follows:—1,200 revs. per min., 5 gals.; 1,400 revs. per min., 10 gals.; 1,600 revs. per min., 15 gals.



CENTRIFUGAL LUBRICANT PUMP FOR USE ON GRINDING MACHINES

DIE FILING MACHINE

A SELF-CONTAINED filing machine of improved design is shown in the accompanying illustration. Motor-drive to the tight and loose pulleys is transmitted through a pair of step cones to the steel head which holds both ends of the files. The upper arm of the head is adjustable for varying length of file, and and the lower arm has adjustments for aligning the file so that the cutting edge travels vertically. Files from 4 in. to 12 in. long can be used, of any shape, and either straight or tapered, as well as any thickness of hack saw blade, all cutting being done on the down stroke and release on the up stroke.



MOTOR-DRIVEN FILING MACHINE WITH FOUR-SPEED CONE PULLEYS.

The table is 17 in. by 18 in., and 39 in. high above the floor. It is grooved diagonally with small holes to let filings drop through, a

blow pipe being fitted to keep the work clear. A seven degree tilt in each direction is provided, and a clamping arm is also arranged, which has a double hinge, and screw adjustments for clamping work to the table, enabling the friction between the work and the table to be regulated so as to eliminate oscillation of work when the file releases on the up stroke.

The machine has an adjustable stroke from 1 in. to 7 in., weighs 375 lbs., and requires floor space of 22 in. by 36 in. It is built by W. D. Rearwin, Grand Rapids, Mich.

HEAVY DUTY SINGLE PURPOSE LATHE

THE Hyde Engineering Works, William Street, Montreal, have brought out a new design of heavy duty lathe for machining H.E. shells from 4.5 in. up to and including 9.2 inch. The design, we understand, is a combination of ideas of several engineers connected with a number of the largest shell plants in the Montreal district. Fig. 1 shows the machine fitted with a turret head, although it has been found that a turret is not always entirely satisfactory for boring heavy shells. In many cases firms making the latter have adopted various methods of boring.

This lathe can be equipped with a tailstock cast solid on the carriage instead of the turret, having a spindle (or boring bar) of 5 inches diameter; the spindle having a large standard taper hole for holding the various boring tools. Under these circumstances the shell would be held in a chuck, and would revolve with the lathe spindle. In addition to the foregoing, if so desired, the shell can be secured in a cradle cast solid with the carriage; in which event a special boring bar bolted to the face plate of the lathe spindle is furnished.

The general design and construction of this lathe appears to combine strength with efficiency. There is also an absence of unnecessary and complicated devices, thereby contributing to accurate operation even with unskilled labor. The headstock is cast solid with the bed of the lathe, and the housings are fitted with bronze bearings, which offer a projected spindle area of 60 square inches on the front bearing and 27½ square inches on the rear. The face plate is solid with the spindle, which is a steel casting, having an overall length of about 38 inches. The front bearing is 6 inches in diameter by 10 inches long, and the rear bearing is 5 inches diameter by 5½ inches long. Lateral motion is taken up by means of fibre washers, placed on the inner side of either housing, adjusting nuts for taking up the wear being located at the back of the rear bearing. The end wear is reduced to a minimum by use of a thrust bearing placed directly behind the face plate. This bearing consists of two hardened steel discs and a series of ⅝-inch steel balls held in a brass casing. The spindle has a large hole through the centre, and can be equipped with the necessary attachments for operating the chucks with compressed air.

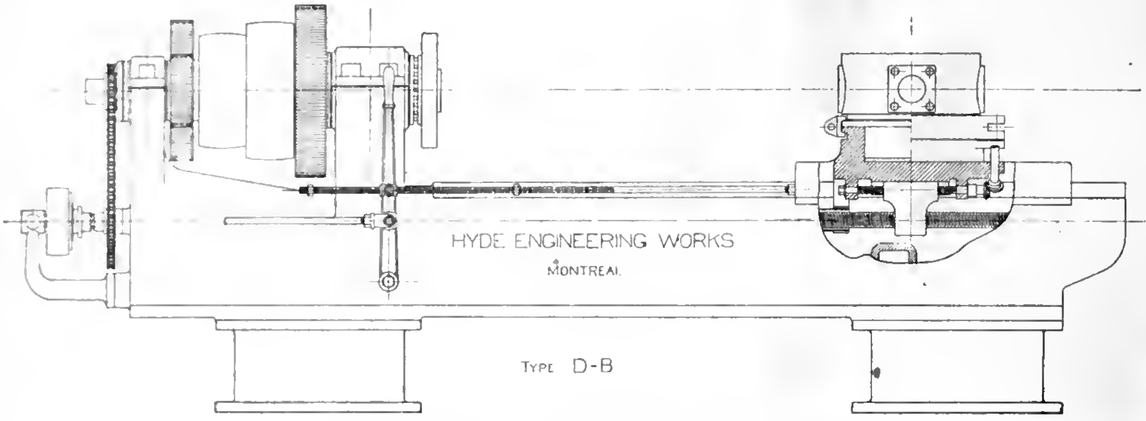


FIG. 1. HEAVY DUTY SINGLE PURPOSE LATHE.

Drive Feature

The drive is obtained from cone pulleys, 15 and 16 inches in diameter of 6½-inch face; these, with heavy cast iron gears of 3 and 4-inch face, offer a speed ratio of 1 to 8.9. The carriage is of extra heavy design, and is equipped with hand-feeding arrangement. A feature of the construction is the method of securing the turret to the main saddle. In addition to the central bolt, a specially-designed adjustable clamping band insures a maximum degree of rigidity and stability. This clamp is operated by means of a toggle device, which also controls the locking pin mechanism. The

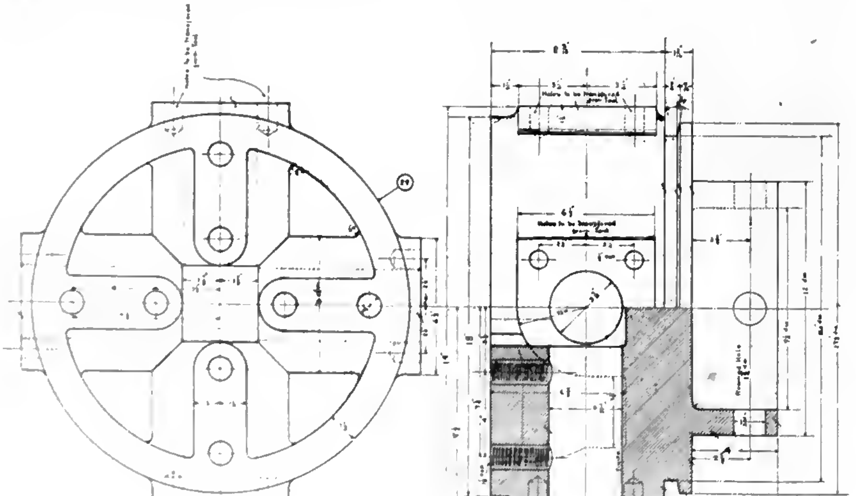

FIG. 2. PLAN AND SECTION OF TURRET HEAD.

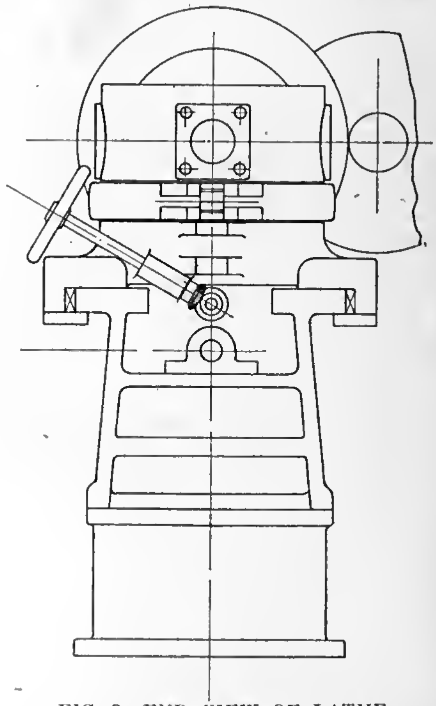

FIG. 3. END VIEW OF LATHE.

carriage is fitted with gibs at the front and rear for accurate alignment. Positive feed is obtained by the use of sprockets connected by a heavy chain; and several changes of feed are available by using different sprockets. The lead screw is placed between the ways of the lathe, so that the pull on the carriage be-

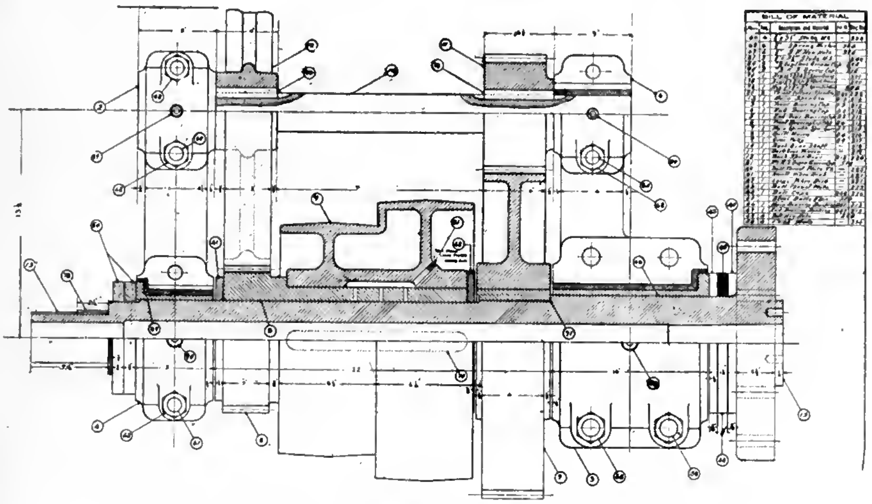

FIG. 4. SPINDLE ASSEMBLY, SINGLE PURPOSE LATHE.

ing in the centre reduces any tendency of uneven wear upon the ways of the lathe. The carriage nut is of the solid type, and by means of an auxiliary screw has lateral adjustment for hand feed. The power feed is semi-automatic; an adjustable rod, one end of which is secured to the carriage, passing through a knuckle on the feed lever. Stop nuts can be located on this rod to release the feed at any desired point. The reverse motion of the carriage is rapid, being obtained by a friction clutch and pulley driven from the main or counter-shaft overhead. Provision has been made for several speeds of feed ranging from 1-64 to 1/4 inch.

Interchangeable Parts

All parts of these lathes are interchangeable, and repairs or changes from boring to turning, or vice versa, can be accomplished with little interruption or loss of time. The length of the carriage is 36 inches, and the extreme travel, 54 inches. Diameter of turret is 18 inches, with holes of 3½-inch diameter. The tailstock, which slides into the centre of the ways, has a bearing of 24 inches long, and is rigidly clamped. The boring bar is 5 inches in diameter, and has a bearing 24 inches long. The length of the ways is 90 inches, and the overall length is 114 inches. The total area of carriage bearing is approximately 288 square inches, and the total weight of the lathe finished is about 9,000 pounds.

WIRE COILING MACHINE

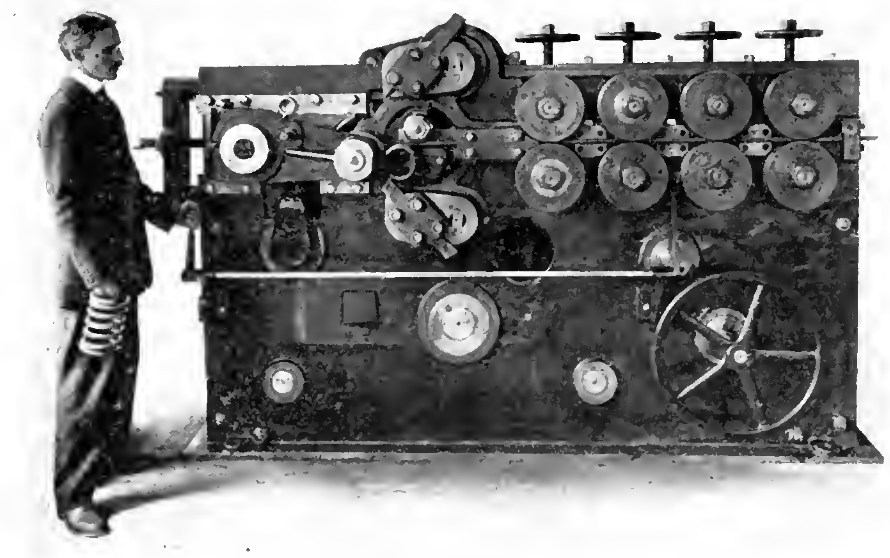
ONE of the largest cold coiling machines ever built is shown in the accompanying photograph, which shows a machine capable of handling oil-tempered stock 5/8 in. square. It is adapted to making extension or compression springs, and will feed as much as one hundred feet of wire into a single spring.

These machines do not produce the springs by coiling around an arbor, but by feeding the wire forward by feed rolls against a coiling point or deflector, a predetermined amount of wire being put into each spring by the machine. Coiling and cutting off are alternately performed automatically, the coiling mechanism being stopped while the spring is being cut off. The only function of the arbor is to provide a cutting edge against which the cutter may carry the wire when shearing it off.

The diameter and contour forming mechanism is controlled by means of a cam, the design of which is such that only one cam is needed to produce any kind of a taper spring, and a single pair of cams will produce every variety of barrel-shaped springs.

The pitch is controlled automatically, and springs may be produced with an open spiral, or the end coils may be laid close to any desired extent. This latter feature obviates the costly method of squaring ends by heating and pressing.

This No. 5 Universal Coiler is the largest of a series of such machines designed and manufactured by Sleeper & Hartley, Inc., Worcester, Mass. It occupies a floor space 6 ft. by 8 ft.; weighs 15,000 lbs., and handles 5/8 square stock at a speed of about 50 ft. per min.



COLD COILING MACHINE FOR HANDLING 5/8-IN. SQUARE OIL-TEMPERED STOCK.

TOOLS AND TEMPER

THE use of poor tools is an economic waste that is almost a tragedy. This is true not only because good tools do better work, but also because they put the workman in a better frame of mind so that he will have pleasure in turning out his work. Putting a man in tune with his job is largely a matter of furnishing the proper equipment and conditions.

The man who quarrels with his tools is not a good workman because his physical and mental energy is expended in the wrong direction. The expert motorist does not need to think of the proper levers to operate in an emergency. He thinks only that he must stop quickly. Hands and feet obey unconsciously. So with tools. They should perform their functions so well that their operation is practically automatic. The operator should be free to think only of the results he wishes to achieve.

Every skilled workman has a certain rhythm with which he performs his daily task. This rhythm, because largely unconscious and automatic, makes his work not only easier but also more accurate. Disturb this rhythm by compelling him to use poor tools, so that he must consciously direct his motion, and you will lower the quality and quantity of his work.—Herbert's Monthly.

NO "HALF COCK" C.M.A. ACTIVITIES

THE trend of the resolutions passed at the recent Canadian Manufacturers' Association Convention gives unmistakable evidence that our own and the Imperial Government have the earnest and undivided support of the members, both individually and collectively. Will winning the war in this one-sided fashion usher in commercial failure as a result? In Britain, as in Canada, manufacturers are bending every energy to meet the military and naval situation and little dissatisfaction is now expressed at the results. The latter are in fact so gratifying and have been so for some considerable time past, that those responsible for our trade and commerce are taking opportunity to cast around and exercise their minds over peace-time eventualities. Withal, it may be said that there is little indication in Canada, at least, of encouragement to our manufacturers to anticipate and prepare for the trade upset and trade war that is practically certain to ensue when hostilities in the field cease.

Of the various resolutions presented and carried at the C.M.A. Convention, this much may be said, that all of them merit the attention and consideration of responsible Government at Ottawa. Not only so, but we are of opinion that just the necessary pressure will be forthcoming to develop action there. The election of Col. Cantley to the president's chair was not of course fortuitous at this time, as he was next in order of precedence, yet, under such circumstances as Canadian manufacturers now find themselves, his elevation to the position of chief executive officer of the association must be conceded the best possible. We not only expect to see the C.M.A. make rapid strides as an institution, under his influence and direction, but its being made the instrumentality through which the Dominion Government will initiate and provide for the progressive development of an industrial and commercial enterprise, from which the present administration and its predecessors have held back, or to which nothing but callous indifference has in the past been exhibited.

At no time in its history, has the Canadian Manufacturers' Association Executive had a like responsibility placed upon its shoulders as has that appointed for the ensuing year; on the other hand the opportunities for worth-while achievement are meantime more diversified and great, and, actively and passively, the backing of our citizens generally is more substantial and solid. The new president's attitude on the Sunday labor question—no "half cock" treatment will, we think, be characteristic of the like attitude to be taken by his executive in prosecuting its work of Government regeneration.

INCREASED PRODUCTION THROUGH CO-OPERATIVE EFFORT

AN article under the above heading in another section of the present issue merits some attention from our foremen and superintendent readers, the particular feature discussed being one that is probably overlooked in these strenuous days and nights of munitions production. We are inclined to think that little thought has been given, much less little effort made to bring the night and day operator together on a common-interest output basis. The suggestion that loss of output results, because the night and day shift men on individual machines never see each other, is a pertinent one, and gains point from the instances quoted which came under the observation of our correspondent.

The manufacture of munitions is not competitive, and a two-shift plant operation is meantime quite common in our machine shops, etc. Much valuable data, comparative with respect to operator output must therefore be readily at hand. In view of this, we are of opinion that an interchange of experiences in our editorial columns would be extremely opportune, contributing, as it inevitably will to not only an increased national response to the call of Empire, but to a more highly developed mechanic intelligence. Time and temper lost by one or other, or even by both operators on a particular machine through more or less paltry and many times imaginary inconveniences, affect materially a shift output, and if, by the slight effort required to assimilate as far as possible the individual traits and working methods of each pair of men, these two factors can be eliminated, the outcome will surely be worth while.

PRESENT CONDITIONS AND LATER PROBLEMS

DISSERTATION on "after the war" and the "future of munitions factories," have become frequent to the point of being commonplace. Schemes of many kinds have been advanced regarding the ultimate fate of war-time industrial establishments, but they all lack that definiteness which is essential to the success of any commercial proposition. Haphazard methods cannot compete against organized efforts, and these in turn cannot be inaugurated without some definite purpose in view.

Two outstanding features of the present situation would seem, however, to offer promise of automatically adjusting themselves to subsequent conditions, i.e., the disposal of specialized machines, and the absorption of temporary labor. While many machine tools have been made to special designs, they have accomplished such satisfactory work that their ultimate consignment to the scrap heap will be more profitable than reconstructing them for other purposes, or keeping them in storage on the chance of ultimate utilization. This has been rendered possible by the high degree of simplicity and "single purposeness" which has been evidenced in later machines.

That the many machine operators, pro tem, will elect to remain permanently in machine shops, under more or less confined conditions and reduced wages when peace returns, seems rather unlikely. Patriotic impulses and financial returns have been the principal sources of much present energy but a return to more placid, though less profitable paths will be welcomed by many workers with a corresponding reduction in one feature of a problem which persists in the minds of many manufacturers.

INDUSTRIAL NOTABILITIES

ALBERT FRANK FIFIELD, general manager the Metal Drawing Co., St. Catharines, Ont., was born at Lowell, Mass., February 8, 1876, the son of Frank and Abie Mary (Cummings) Fifield, Ashland, N.H. He was educated in the public and preparatory schools of New Hampshire, and began his business career by operating a machine shop at Ashland, N.H., between the years 1897 and 1905, coming in the latter year to the Jenckes Machine Co., Sherbrooke, Que., as construction superintendent. In 1907 he went into business at St. Catharines, Ont., by engaging in the buying and selling of machinery.

ALBERT FRANK FIFIELD

Later he organized the Reo Sales Co. at St. Catharines, the special purpose of which was the distribution of the Reo Motor Car for pleasure and commercial service in Canada. A coast to coast trip on a Reo car, the latter being furnished by Mr. Fifield, as well as the operator crew, was undertaken and successfully accomplished, a piece of enterprise which had the unique distinction of being the first of its kind in the Dominion. In 1914 the Metal Drawing Co. was organized at St. Catharines, with Mr. Fifield as general manager, following which the latter sold out his various other business interests.

Mr. Fifield takes a live interest in many of St. Catharines' activities, among which may be mentioned his inauguration of the American Patriotic Fund, which is partly diverted to the general city charities; his past chairmanship and present executive membership of same, and his committee membership of the Canadian Patriotic Fund.

He married Velma Faunce Linscott, daughter of A. N. Linscott, Damarscotta Mills, Me., on May 25, 1904, the family consisting of two daughters. His clubs are: St. Catharines, Niagara (Niagara Falls, N.Y.), Buffalo Motor, St. Catharines Golf, and St. Catharines Canoe. His societies are the A.F. and A.M., and his recreations motoring, angling and hunting.

In religion Mr. Fifield is a Protestant independent. His residence is at 157 Ontario Street, St. Catharines, Ont.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., June 19, 1916.—The industrial situation is gradually assuming a condition which seems to indicate that the top has been reached. While it is not anticipated that marked declines will be shown in many raw or semi-finished products, it is thought by many that prices will, with few exceptions, remain at their present levels for some time, until further developments justify a change. In some industries a diminution in the amount of night work appears to indicate that the apex of production has been reached, but the majority of industrial plants throughout the country are still working at forced pressure on accumulated orders. The monthly commercial letter of the Canadian Bank of Commerce states that "At no time has a larger proportion of the industrial plants of the country been actively employed than to-day, and an increasing quantity of domestic raw material is being utilized. Textile, iron and steel, boot and shoe, packing and other industries are operating as fully as the supply of labor will permit." The value of the manufactured products of Canadian industries for 1910 was $1,164,000,000; while it is conceded that this year's products will total approximately $2,000,000,000

Pig Iron.

While the situation is apparently unchanged there is a tendency to lower prices. Production continues at furnace capacity, with no cessation in the demand for steel-making pig; and slightly additional inquiries for foundry iron. A reduction of 25 cents per ton is general in foundry pig quotations.

Steel.

The general iron and steel situation is quiet, and with the majority of mills working to capacity it is not expected that much additional buying will be done for some time. It is anticipated that early in the fall increased activity will develop, when consumers, who have not yet covered their requirements for the last quarter of this year and the early part of next, will be in the market. Recent inquiries for plates have been comparatively light and near by positions have been obtained at prices slightly lower than the nominal quotation. Mills are however unable to take large orders for delivery under five or six months. Following the slight activity recently shown in sheets, the market has quietened down again as the trade appear to be well covered for the remainder of the year. The demand for all wire products is very heavy and the market is strong; prices on plain and galvanized wire have been advanced $4 a ton, Pittsburg. An additional $2 a ton is also noted in the Pittsburg quotation on railroad spikes. Wrought iron pipe and boiler tubes are in good demand and quotations are firm.

Metals.

With the exception of aluminum, which is growing firmer, all the metals are unsettled and quiet. Spelter is quiet and unchanged. Lead is slightly easier in the open market, but Trust prices are firm. Antimony is very dull, on sharp declines. Aluminum is showing a little increased strength after a period of steady going.

Copper.—There have been rumors of heavy English buying pending, but nothing has developed to confirm this report. During the past week the London market has declined £10½ on standard spot; £9½ on futures and £2 on electro spot; present quotations being £113, £110 and £140 respectively. New York quotations have declined ¾ cent with current prices nominal at 27½c for prime lake and electrolytic, and 25¼c for castings. Dealers here report a quiet, but steady, market with prices unchanged; present quotations being 32c for lake and electrolytic, with castings at 31c per pound.

Tin. — Future prices are becoming easier, consumers being attracted by the declining quotations, and considerable inquiry has resulted. However, there is apparently little ground for anticipating any sharp decline in the price of tin, as the consumption at the present

time is continuing at a record rate, with little prospect of relief from new mills now in course of construction. Daily weakness in the British markets has resulted in a total decline on the week of approximately £9½ on spot and futures; the former being now quoted at £178 and the latter at £178½; straits tin is slightly higher at £179. New York has been effected by the foreign situation to the extent of a 3c decline on straits tin, latest quotation being 41¾c per pound, nominal. The local market has not yet been affected by foreign conditions and dealers here report an unchanged situation with prices steady at 48c per pound.

Spelter.—No developments have taken place during the week; holders of metal do not appear anxious to offer it for sale, and are looking forward to a stronger market. New York is quoting 13 1-6c, which is a decline on the week of ⅞c per pound. Montreal dealers report unchanged conditions of weakness. Prices are firm at 17c per pound.

Lead.—The Trust price is firm at 7c with the outside quotation 1-5c lower. The local market is quiet with prices firm at 9c per pound.

Antimony.—The available supply of antimony is apparently increasing and the market is becoming very dull. New York has declined on quotations to the extent of 2½c on all grades; the nominal price being 20c per pound. Dealers here are quoting 31c on a weak and declining market.

Aluminum.—While no change is noted in the local market, an advance of 3c is reported on the New York Market. It might be interesting to note that the price of aluminum at present around 66c, was about 32c a year ago, while the average price during the year 1914 was slightly under 20c per pound.

Machine Tools and Supplies.

The general situation throughout the machine tool industry is practically unchanged. Large shell manufacturers are still receiving equipment, and the chief draw back to maximum production is the inability to obtain delivery on the required machinery. The demand for the lighter tools is gradually decreasing, the greater volume of business being done in the heavier tools. The demand for all classes of supplies continues heavy, the situation still remaining difficult owing to the scarcity of raw material. While prices generally are unchanged the tendency is for slight reductions.

Scrap

Dealers in old material are reporting a fair volume of business, but no increased interest is being shown by consumers and dealers are not anxious to stock up at present prices. With the exception of the light grades, scrap coppers are off ¼c per pound; brass clippings and turnings have declined ½c present quotations being 14½ and 11½ per pound. Wrought iron scrap is more plentiful and a decline of ½c is noted on the local market. Scrap zinc is stronger, an advance of ½c putting the current price at 11½c; and scrap aluminum is quoted at 37c, an advance of 1c per pound.

Toronto, Ont., June 20.—The industrial situation continues favorable and the demand for manufactured products is steadily increasing. New industries are being established, and many firms are extending their plants to take care of the increased demand, and also in view of the continued period of prosperity which is anticipated. Production is, however, being curtailed owing to scarcity of labor and of raw materials. Although greater efficiency in operation is off-setting this to some extent, it is generally anticipated that the shortage of some manufactured goods now being felt will become more acute later on in the year owing to the greater number of enlistments and to there being little chance of any improvement in the raw material situation.

Although the upward movement in prices appears to have almost come to a standstill, there is no indication of any weakness in the situation. Prices of manufactured products have been adjusted to meet the cost of raw materials, and, as it does not appear that the latter will advance further, to a marked extent at least, and only in isolated cases and subject to special conditions, it is unlikely that finished goods will advance, although prevailing high prices will no doubt be maintained for some time to come. Prices of steel products generally are unchanged, except boiler tubes, which have advanced again. The ingot metal markets are still weak, and further declines have to be noted. The demand for machine tools is more active, following the placing of orders for large calibre shells.

Steel

The market continues very firm and prices are practically stationary. Indications point to the top of the market having about been reached, although further advances in some steel products subject to certain conditions may be expected. There is, however, no sign of weakness in the steel market, and there is every reason to believe that the present high level of prices will be maintained for the remainder of the year. The mills are as active as ever, orders for munitions accounting for a considerable proportion of their output. The only advance of importance to note this week is lapwelded boiler tubes. The new prices, 10% higher, are for tubes made to the new specifications, which calls for thicker metal. Some makers of iron and steel tubes are not taking on new orders, as they are filled up for the remainder of the year. Prices of wrought iron pipe are very firm; the current demand is heavy, and some mills are sold up for three or four months. The skelp situation is unchanged, and deliveries are still very backward.

Prices of wire rods are firm, and supplies are scarce owing to the export demand for rod material being heavy. It is very difficult to get wire rods from the States, as the makers there are filled up with orders. Boiler and tank plates are very firm and prices unchanged. The new demand for plates is not as urgent as it was some time ago, but deliveries are still backward.

The new demand for sheets, although fairly heavy, has quietened down to some extent, the trade being covered for the remainder of the year. Specifications, however, are reported to be coming in freely, and the sheet mill interests believe that the lull is temporary. Prices of black sheets are firm, with an upward tendency owing to the possibility of higher prices having to be paid for sheet bars. Galvanized sheets are irregular, but more interest is being shown by consumers in the market. The decline in spelter has caused a weaker tendency in sheets, but prices are unchanged in the meantime.

The steel market in the United States is quieter, and it is not believed that there will be much new buying until September. Import inquiry for finished steel continues heavy, but domestic buying is lighter. All the mills have large unfilled tonnages, and it is considered probable that even if demand declined further there will be little, if any, reduction in prices. Steel bars are unchanged at 2.75c and plates at 3.75c, but beams are a little lower at 2.50c Pittsburgh. Open-hearth billets and sheet bars have declined $2, and are now quoted at $40 per ton Pittsburgh.

Pig Iron

The market is quiet and prices have an easier tendency, although unchanged in the meantime. The demand for steel-

---

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

making grades is as insistent as ever, and foundry irons are more active.

Scrap

The market is dull, with prices weak, being influenced largely by the decline in ingot metals. Buying is of the hand-to-mouth order, and is in light volume. Heavy melting steel is firm and higher, but zinc and lead have both declined.

Machine Tools

Business in machine tools is more active than it has been for some time, due principally to the recent orders for large calibre shells. Some new firms have received orders and so require complete equipments. The machine tools required consist principally of large swing lathes, high-duty drills and cutting-off machines. Deliveries are good on heavy tools, but backward on standard equipment.

Supplies

The demand for machine shop supplies continues brisk, and prices are much steadier. Brass tubing has advanced, as has also asbestos wick packing. Alfalfa belting has advanced about 25 per cent. This is a fibre belting which is used extensively in the operation of agricultural machinery. Linseed oil has again declined, and is now quoted at 75c and 78c for raw and boiled respectively. Turpentine is also lower at 62c per Imperial gallon. Gasoline is unchanged, but firm, and may advance.

Metals

A general weakness prevails in the metal markets, with a decline in prices of all except lead and aluminum. The weakness is really due to the fact that production is now greater than consumption, although the latter is still heavy. There has been some falling off in war orders, and the inflated prices are keeping consumers out of the market. Tin is, however, an exception, as this metal is not being used for munitions, and is, therefore, not subject to the same influences. The tin market, notwithstanding this, is being affected by the other markets, and is lower. Copper is lower, due to second-hands making concessions, but the position of this metal is a strong one, and a reaction to higher prices is quite probable. The demand for lead has fallen off, and the market has a weak tendency, although prices are unchanged. Spelter and antimony are both lower, but aluminum is unchanged.

Copper.—The market is quiet and lower, with second-hands making further concessions. Consumers are not in need of spot copper, and the lower prices have not attracted business. Producers are sold up for some months, and they are still holding out for high prices. The demand for copper will be heavy throughout the year, and the market may possibly recover. Quotations are entirely nominal and lower at 31c per pound.

Tin.—The market is weaker, but more in sympathy with other metals than as a result of any change in the situation. A sharp break in London has been followed by a decline here. Consumers are not at all disposed to enter the market at this time, and some sellers report that the inactivity since the first of the month has been most pronounced. Tin is comparatively cheap at present prices, and a recovery is highly probable. Tin has declined 2c, and is now quoted at 48c per pound.

Spelter.—The market is dull and lower, with no improvement in the situation. In some quarters sellers are willing to shade quotations, while future business is also quiet and prices lower. The easing off in spelter is due to the anxiety of second-hands to sell. Spelter has declined 1c, and is quoted at 17c per pound.

Lead.—The market is featureless, and has a weaker tendency, although quotations are unchanged. Buying is light, consumers only covering for immediate requirements.. The Trust price is unchanged at 7c New York, but the outside market is a shade lower. Local quotations are unchanged at 9c per pound.

Antimony.—The market is unsettled and lower, but sellers are endeavoring to maintain prices. No future business is offered owing to the uncertainty of the market. Quotations have declined 2c, and are entirely nominal at 33c per pound.

Aluminum. — The market continues strong, due to heavy demand, which will take care of the entire production. Quotations are firm and unchanged at 65c per pound.

Solders.—The expected decline in solders has materialized, due to the lower prices of tin and lead. A fair demand is reported locally. Guaranteed is now quoted at 29c, and strictly at 28½c per pound.

DOMINION STEEL CORPORATION RECORD

IN keeping with the record-breaking statements that have been coming forward from the steel industry all over this continent, Dominion Steel Corporation reports for the year ended March 31 last the largest profits in its history, net manufacturing earnings rising to $7,004,316, an increase of $3,433,258, or 97 per cent. over the previous year, and an increase over the banner year of 1912-13.

Records in Output

Dealing with the year's operations, Mr. Workman, the president, reviews the difficulties encountered in the coal trade as a result of the shortage of ships and the drain on men resulting from the recruiting campaign. As to the latter, he says that representations were finally made to the Government and in view of the fact that a sufficient supply of coal and steel "is as important as the enlistment of men, orders were issued to discontinue recruiting in and about the collieries. It is estimated that upwards of three thousand men left the collieries and steel works to serve in the Allied armies, the collieries contributing the larger proportion. Vacancies at the steel works have been filled from various sources, and so far there has been no diminution of output."

After dealing with the wage adjustment of January and the recent general advance of 10 per cent., the president gives the production figures for the year. The coal output was 5,261,198 tons, against 4,550,512 the previous year, and 5,051,603 in the active year of 1912-13. Last year's requirements of coal for the steel works amounted to about 400,000 tons more than the previous year.

The tonnage of pig iron produced—329,664 tons, against 187,262 in 1914-15, was slightly less than in 1913-14, when the output was 333,919. The year just past, however, holds the record for the largest production of steel ingots, the total having been 371,086 tons, against 243,313 the previous year. Comparisons of production for two years follow:

	Year ending March 31 1916.	1915.
Pig iron	329,664	187,262
Steel ingots	371,086	243,313
Blooms and billets for sale	142,282	38 231
Rails	35,197	99,929
Wire rods for sale	55,106	14,277
Bars	8,017	14,310
*Wire	36,058	27,175
Nails, etc.	19,262	11,679

*This includes wire used in manufacture of nails shown in next line.

Factor of War Orders

Discussing the general aspects of the year's business, Mr. Workman says: "The most important elements in the steel business continue to be those which have resulted from the war. One-fifth of the steel shipped from the works was in forms suitable for the manufacture of shells. One-half the total output was exported. The destination of the greater part of this was Great Britain or France, but considerable tonnages were sent to South Africa, Australia and United States. British consignments included many parcels for re-shipment to India and the Far East. The benzol works and the 16-inch mill referred to in last year's report were completed and have been kept steadily in operation."

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Magog, Que.—The Dominion Textile Co. will build an extension to the power plant at their mill here.

Beauharnois, Que.—The Howard Smith Paper Co. propose building an extension to their power plant.

Windsor, Ont.—J. G. Hussey, is in the market for tinsmithing tools and machines, also an 8ft. cornice brake.

Trenton, Ont.—The Canadian Sprayer Co. is contemplating the erection of a plant, to manufacture sprayers and gasoline engines.

Toronto, Ont.—The Harbor Commission, will commence at once the erection of a brick machine shop on the Don Division to cost $13,500.

Pembroke, Ont.—The Pembroke Electric Lighting Co. are having plans prepared for a sub-station by R. S. Kelsch, Power Building, Montreal.

Selkirk, Man.—Prof. R. C. Wallace, provincial mineralogist, has gone to the Rice Lake gold fields to make an inspection on behalf of the Government.

Toronto, Ont.—The Ideal Bread Co. propose to build a bakery at an estimated cost of $3,000. Bond & Smith are the architects.

Toronto, Ont. — The Harris Abattoir Co., has had plans prepared for the erection of an addition to its plant, to cost $50,000.

Welland, Ont.—It is understood here that the management of the Canada Foundries & Forgings Co. has under consideration further additions to its buildings and plant.

Lindsay, Ont.—Good progress is being made in the construction of the chemical plant for the Hodgson Chemical Co. Two brick ovens, steam boilers and stills have already been installed. The company will manufacture wood alcohol, acetate of lime and charcoal.

Wolfville, N.S.—Work has been started on the Bay of Fundy tide power project at Cape Split, N.S., by the Cape Split Development Co., of Wolfville. R. P. Clarkson, formerly an electrical expert for United States Government, in consultation with other eminent engineers, is directing the work. Power will be generated by means of the tidal currents for distribution throughout the district.

Exeter, Ont.—C. F. Smalley of the Smalley Mfg. Co., Manitouac, Wis., was in town last week with a view of starting a branch factory, in connection with the Connor Machine Co.

Hamilton, Ont.—Damage amounting to about $15,000 was done by fire on June 13, to the factory of Lumsden Bros., and also to the Jersey Cream Factory, owned by the same firm, and adjoining its other premises on Macnab Street North.

North Vancouver, B.C.—The Wallace Shipyards, have been awarded contracts for the construction of three steel vessels to cost $400,000. The company has purchased a site and will build a new plant, the contract for the first unit having been awarded to T. Allan of Lyon Valley.

Municipal

Moose Jaw, Sask.—The City Council, will spend $12,300 on extensions and the installation of new equipment in the power plant.

Winnipeg, Man.—The Board of Control have recommended the purchase of a motor to drive 5,000,000-gal. pump at the waterworks. W. P. Brereton is city engineer.

Kingston, Ont.—The ratepayers on June 19 voted to ratify an agreement for a supply of electrical power from J. M. Campbell at Kingston Mills to the Utilities Commission. From 300 to 600 horse-power is being secured at three-quarters of a cent per kilowatt hour.

Tenders

Parry Sound, Ont.—Tenders are being called for heating apparatus and electric wiring for a new public school. Full particulars may be obtained from Angus & Angus, North Bay, Ont.

Beeton, Ont.—Tenders will be received until June 30 for heating, ventilating and galvanized iron work for a new school building. Full information may be obtained from the architect, John Wilson, Collingwood, Ont.

Toronto.—Tenders will be received by the Board of Control, up to July 4, for the supply and delivery of one 8-in. water-meter. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders for extension to Front Street sub-station will be received until June 28. Plans, specifications and form of tender may be obtained at engineering office of the Toronto Electric Commission, corner Duncan and Nelson Streets.

Vancouver, B.C. — The undersigned will receive tenders up till June 28, for the purchase of the following lapwelded steel pipe, manufactured by the National Tube Co., Pittsburg, Pa.; 20,000 lin. feet 6-in., 45,000 lin. ft. 8-in., 10,000 lin. ft. 12-in. James Stuart, city purchasing agent.

Toronto, Ont.—Tenders will be received up to July 4 for the supply of one 3-h.p. motor, one 20-inch square base self-feed vertical drill with ¾-inch drill chuck and shafting. Samples of the several articles can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide Street Fire Hall, Toronto.

Prince George, B.C. — Tenders for power plant equipment for the City of Prince George, B.C., will be received at the office of the city clerk, up to July 8, 1916. Specifications and instructions may be obtained at the office of the city clerk, or at the office of the consulting engineers, DuCane, Dutcher & Co., Rogers Bldg., Vancouver, B.C.

The Pas, Man.—Tenders, addressed to H. H. Elliott, M.D., secretary-treasurer of the town of The Pas, Man., will be received up to June 22 for the supply and delivery of the following machinery and materials:—Tender "A"—For the supply and delivery of two sewage lift pumps. Tender "B"—For the construction of a sewage lift chamber. Plans and specifications may be seen at the office of Murphy & Underwood, consulting engineers, Saskatoon, Sask., and the resident engineer, The Pas, Man.

Ottawa, Ont.—Tenders will be received until July 10 for 163,500 lbs. of galvanized iron telegraph wire, delivered at Montreal, Que.; or 128,500 lbs. of same delivered at Kamloops, B.C., and 35,000 lbs. delivered at Vancouver, B.C.; early dates of delivery desired. Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Govern-

ment Telegraph Service at the Department of Public Works, Ottawa; also at the office of J. T. Phelan, superintendent of Government Telegraphs at Vancouver, B.C.

Toronto, Ont.—Tenders for Examining Warehouse will be received until July 17. Plans, specification and form of contract can be seen and forms of tender obtained at the offices of Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., R. L. Deschamps, Central Postoffice, Montreal P.O., and at the Dept. of Public Works, Ottawa .

London, Ont.—By direction of the Honorable the Minister of Militia and Defence, the following old stores at the Ordnance Depot, London, Ont., are for sale by public tender: Leather, old 830 lbs.; old brass, 190 lbs.; old copper, 84 lbs.; old iron, cast, 628 lbs.; old iron, wrought, 57 lbs.; old steel scrap, 734 lbs. These articles may be seen on application to the Senior Ordance Officer, London, Ont. Sealed tenders for the purchase of all or any of these lots will be received until July 1, 1916.

Ottawa, Ont.—Tenders will be received up to July 4 for the construction of reinforced concrete foundations on wood piles or concrete piles, for 1,000,000 bushel storage capacity grain elevator, working house and track shed at Transcona, Man., separate tenders to be submitted for the foundations with concrete piles and foundations with wooden piles, and tenders may be submitted on either or both designs. Plans, specifications, etc., may be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Chief Engineer, Moncton, N.B.; at the office of the General Superintendent, Winnipeg, Man.; at the office of the Resident Engineer, Fort William, Ont.; and at the office of the J. S. Metcalf Co., Ltd., engineers, Montreal, P.Q.

Contracts Awarded

Galt, Ont.—The Bell Telephone Co., have let a contract to P. H. Secord and Sons, Brantford, for the construction of their new exchange.

Longueuil, Que. — Armstrong-Whitworth of Canada have awarded the contract for the addition to their plant to the Dominion Bridge Co. The Morgan Engineering Co., Alliance, Ohio, will supply the machinery for the rolling mills.

Fredericton, N.B.—The Provincial Government have awarded two contracts to W. R. Fawcett, of Temperance Vale, York County. One of the contracts is for St. Nicholas River Mouth Bridge, in Kent County. This is to be a structure of three covered spans, each 160 feet long. The contract price is about $30,000. The other contract is for two bridges, known as Upper Sackville and Anderson Bridges, in Westmoreland County. The contract price for the combined work is about $11,500.

Personal

Joseph T. Rolph, founder of the firm of Rolph & Clark, lithographers and engravers, Toronto, died on June 13, aged 84.

S. H. Reynolds, chairman of the Greater Winnipeg Water District Commissioners, died suddenly in Chicago on June 16.

L. T. Walls, Winnipeg, has resigned from the sales staff of the Steel Company of Canada, and joined the Manitoba Rolling Mill Co., Winnipeg.

H. S. Crowell, manager of New Burrell-Johnson Iron Co., Yarmouth, N.S., has been elected to the executive of the Canadian Manufacturers' Association.

H. J. Fuller, president, and **T. McMillan,** vice-president of the Canadian Fairbanks-Morse Co., and **C. H. Morse,** president of the Fairbanks-Morse Co., Chicago, were in Toronto last week inspecting the local plant.

Col. Thomas Cantley, president of the Nova Scotia Steel & Coal Co., and chairman of the Munitions Resources Commission, has been elected president of the Canadian Manufacturers' Association for the ensuing year.

James M. Nelson, who recently resigned as superintendent of the openhearth department of the Carnegie Steel Co. Works at Youngstown, Ohio, has been appointed superintendent of the open-hearth and duplex steel departments of the Algoma Steel Corporation at Sault Ste. Marie. Ont. He has had over 20 years' experience as a foreman and superintendent. At Sault Ste. Marie he will be associated with Lawrence H. Cooney, general superintendent of the Algoma properties, formerly a Youngstown man.

Wood-Working

Moncton, N.B.—Tuttle's lumber mill, was burned down on June 11. The loss is estimated at $5,000 with no insurance.

Brockville, Ont.—Fire in the planing mill of the McLaren Co. did considerable damage on June 14, which is only partially covered by insurance.

Marine

Thomas Muir Nairn, for many years superintendent of the Donaldson Steamship Line, died at his home, Notre Dame de Grace, Montreal, on June 6.

"Keewatin" to New Orleans.—It is reported that the Keewatin, which has been engaged for many years bringing coal from Oswego to Belleville, is to be taken to New Orleans, where it will be used in trade around the river and gulf.

"City of Midland" Raised.—The hull of the steamer City of Midland, which was burned last March and sank alongside the G. T. R. wharf at Collingwood, Ont., was successfully floated on June 10. It now lies by the drydock, where temporary repairs will be made, preparatory to remodelling into a tow barge or scow.

Steamship Directors Elected.—At a recent special meeting of the shareholders of the St. Lawrence & Chicago Steam Navigation Co., the following Board of Directors was elected:—James Carruthers, J. W. Norcross and Horace Smith, of Montreal; M. J. Haney, J. H. G. Hagarty, Aemilius Jarvis and A. A. Wright, of Toronto; J. P. Steadman, of Hamilton. At a subsequent meeting of the new board, J. W. Norcross was elected president and M. J. Haney vice-president, succeeding W. D. Matthews and Sir Edmund Osler. James Carruthers is president of the Canada Steamship Lines, M. J. Haney vice-president, and Messrs. Steadman, Jarvis and Norcross are directors.

Trade Gossip

The St. Maurice Paper Co. have awarded the general contract for their new mill at Cap de la Madelaine to the George A. Fuller Co., Montreal.

John T. Wilson, Ltd., of Toronto have had their charter extended to carry on business as iron and brass founders, machinists and tool makers, etc.

Victoria, B.C.—The forest revenue for the province for the month of May was very satisfactory, amounting to $189,000, which is larger than for the same month of last year, and in excess of the figures for May, 1914.

The Siemens Co. of Canada have received a $21,000 order from the Dept. of Public Works, Ottawa, for 17¼ knots of deep sea type submarine cable for Government telegraphs.

Canadian Fairbanks-Morse Co. have been appointed agents for Canada by the American Spectacle Co. of New York, one of the largest makers of

THE A. R. WILLIAMS MACHINERY CO., LTD.

ST. JOHN, N.B. TORONTO WINNIPEG VANCOUVER

Canada's Leading Machinery House

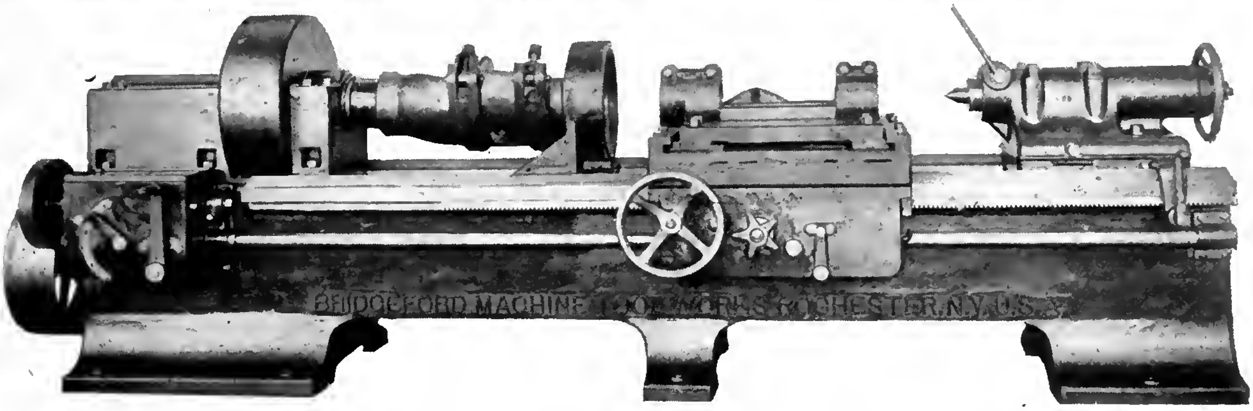
9.2 Shell Insert

Watch For It Next Week

"You Are Known by Your Products"

Link yourself up with Canada's Leading Shell Machinery House, profit by our experience in equipping munition factories and you will "produce a reputation" that will make you known as the Leading Shell House of Canada.

Next week's issue will contain a wide and exceptional collection of 8" and 9.2 shell machines. If you are unable to wait—write us immediately and we will send you advance information.



The Bridgeford Lathe illustrated here is typical of our high-grade machinery. It is arranged for boring (with special carriage for rough turning) and is a leader among the many first-class tools which we have investigated and can highly recommend for producing 8" and 9.2 high explosives. In selecting the tools for this class of work, we have kept before us our usual high standard of production, and our endorsement is backed up by our wide experience in equipping munition factories for the past eighteen months.

The A. R. Williams Machinery Co., Limited

64-66 FRONT STREET WEST :: :: :: TORONTO

If any advertisement interests you, tear it out now and place with letters to be answered.

workmen's spectacles and eye protectors in the United States.

Galt, Ont.—Geo. A. Dobbie, president of the Victoria Wheel Works and the Canadian Brass Co., and director of the Crown Hat Co., has acquired the interest of Andrew Newlands in the A. Newlands Co. and the Galt Robe Co.

The A. R. Williams Machinery Co., Toronto, have sold to the Western Machine Co., Port Arthur, Ont., a number of lathes, drills, cutting-off machines, boring machines, Beaudry hammers, furnaces, millers, and sand blast equipment.

Embargo on Feldspar.—The Dominion Government have placed an embargo on the export of feldspar. Considerable quantities of this material have for several years been shipped from the Kingston, Ont., district. The trade is valued at about $100,000 a year.

British Scrap Prices. — In a circular sent out through the Press Bureau, it is stated that the Ministry of Munitions are considering the question of fixing maximum prices for heavy steel melting scrap and for steel turnings and borings, and a notice accordingly may be expected in the London Gazette.

The General Car & Machinery Works of Montmagny, Que., have rebuilt their plant, which was recently damaged by fire. The plant consists of steel, iron and brass foundries, forging and machine shops, giving a total floor area of 117,000 sq. ft. A power plant has been installed having a capacity of 1,000 h.p.

Montreal, Que.—It is reported that the Canada Cement Co. has reopened its large cement plant at Exshaw, Alta., which employs about 300 men when working to capacity. It is probable that, owing to the increasing demand for the company's product in the West, the Calgary plant will be started up later on.

The Montreal Jeffery Sales Co., under the management of James L. Kreg, and with showrooms in the Forum Building, St. Catherine Street, Montreal, has been organized to represent the Thomas B. Jeffery Co., of Kenosha, Wis., manufacturers of Jeffery pleasure cars and trucks.

Toronto, Ont.—The movement for the establishment of an Industrial and Publicity Bureau for the city has been advanced by the appointment of a special committee of seven at the meeting held in the City Hall to formulate a definite scheme of organization for submission to a general meeting of citizens at a later date.

The New York & Ontario Power Co., a corporation organized under the laws of New York State, recently made application through Spratt & Van Kennen for permission from the war department to suspend an electric transmission line across the St. Lawrence River for the conveyance of electric current from Waddington to a point on the Ontario shore near Morrisburg.

The Toronto Pressed Brick Co., Milton, Ont., and the Medina Shale Brick Co., Streetsville, have amalgamated with the Milton Pressed Brick Co., Milton, Ont., and a company has been incorporated with a capital of $1,500,000. The head office will be at Milton, Ont. J. S. Cammell is president and managing director, and F. R. Connel is vice-president. The directors are P. Stillwaugh, J. McBain and W. D. Lumis.

Electric Vibrators made by The Magnetic Mfg. Co., Milwaukee, Wis., are described fully in bulletin No. 5. These electric vibrators are designed for foundry use and their construction and method of operation are dealt with at length. The various types are illustrated as are also the motors and attachments. A price list covers the complete line and also vibrator accessories.

The Jeffrey Manufacturing Co., of Columbus, Ohio, announce the reopening of their North-Western branch office at Seattle, Wash., and the appointment of Percy E. Wright, consulting mechanical engineer, as district manager for Oregon, Washington, Alaska, British Columbia, and Alberta. Mr. Wright, who has been in the North-West since 1910, and whose connection with the company dates back to 1902, has had a wide and varied experience and training in the handling of the Jeffrey line in the engineering, construction and sales departments.

The Roelofson Machine & Tool Co., Galt, Ont., are building a new plant, which will be equipped for making special machinery and small tools. The main building will be 182 ft. by 104 ft., one storey of brick and steel construction, and saw tooth roof. The plant will be driven throughout by Hydro-Electric power. The company, who have represented the Potter & Johnson Machine Co. of Pawtucket, R.I., for some considerable time, will make Galt a distributing point, and for this purpose will utilize part of the plant as a warehouse for machine tools.

Export Tonnage Increases.—In the matter of available tonnage for Canada's export trade there has been considerable improvement in the last couple of months, according to information received by the Marine Department. There is plenty of tonnage now for all the traffic offering, according to reports received in Ottawa. The substantial reduction in ocean freight rates since the opening of navigation on the St. Lawrance this spring is considered a corroboration of the improvement regarding available tonnage. The reduction in freight rates on the lakes has been slightly greater than that in the ocean rates.

Staff Changes.—A number of changes have recently been made in the management of the Manitoba Bridge & Iron Works, Winnipeg, Man., J. A. McCulloch, who has been sales manager for the past five or six years, has been appointed general superintendent with jurisdiction throughout the plant. Mr. McCulloch has bad a wide experience in the structural, mechanical and the sales end of the business. H. A. McKay, chief engineer, takes over supervision of the sales department, while still retaining oversight of the engineering side of the plant. Mr. McKay's connection with the Manitoba Bridge & Iron Works begain in 1908, prior to which he was in the engineering department of the C.N.R. at Toronto. E. Stewart, who has been acting general superintendent for the past few months, is still with the firm although in another capacity.

Building Notes

Montreal, Que.—The Keith Orpheum Co., will build a large theatre here which will have a seating capacity of 3,000. A site has been secured.

New Incorporations

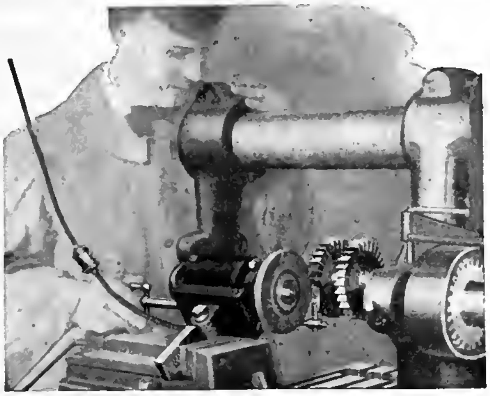
The Champion Ignition Co., has been incorporated at Toronto with a capital of $40,000 to manufacture electrical ignition equipment and electrical apparatus at Walkerville, Ont. Jos. W. Coatsworth of Walkerville is the attorney.

The Frontier Pulp and Paper Co., has been incorporated at Toronto with a capital of $50,000 to carry on a paper and pulpwood business at Thorold, Ont. Incorporators, M. D. Feigenhsohn, G. W. Knox and T. F. Battle all of Niagara Falls, N.Y.

Feldspars, Ltd., has been incorporated at Ottawa with a capital of $200,000 to develop, smelt and otherwise treat ores metals and minerals. Head office to be situated at Toronto, Ont. Incorporators, M. A. Richardson, A. C. Fleming and J. R. Cook all of Toronto.

The Auto-Knitter Hosiery Co., has been incorporated at Toronto with a capital of $40,000 to carry the business of knitters and cotton spinners, etc. Head office to be situated at Toronto. Incorporators, J. M. Bullen, J. H. Fraser and H. L. Steele all of Toronto.

Aikenhead's DUMORE GRINDER



SPEED

To do quick, accurate work, speed is absolutely necessary. If you are not giving your wheels the correct surface speed, they will break down, making it impossible to maintain accuracy. The DUMORE with 10,000 R.P.M. on the motor spindle, and 30,000 R.P.M. on the internal attachment, gives you a cutting speed that enables the wheels to clear themselves; and enables the operator to maintain size.

As the name implies, it will "DO MORE" than the ordinary Portable Grinder, and tool and die makers everywhere give it the preference. Try it and be convinced.

Aikenhead Hardware Limited

O. K.

"Wish to say that in my estimation Geometric Tools are O.K."—J. W. D., Shop Foreman.

The opinion of this Shop Foreman is the opinion of all users of Geometric Screw-cutting Tools

Every Die Head and Collapsing Tap bearing the stamp of distinction —*"Geometric"*—has been tested by experts.

Can be arranged with shank to fit any make of Screw Machine.

Geometric Threading Tools will produce for you either external or internal screw threads of any diameter, length, pitch and form.

Make our acquaintance now, through our literature, and when you are ready to order, you will know just the tool needed. Tell us the class of thread-cutting that interests you, and we will send booklet describing tools to suit.

The Fegles-Bellows Engineering Co. has been incorporated at Ottawa with a capital of $100,000 to carry on the business of general contractors, and engineers. Head office to be situated at Winnipeg, Man. Incorporators, D. B. Fegles and W. S. Bellows, of Fort William, Ont.; and W. S. Whitney, of Winnipeg.

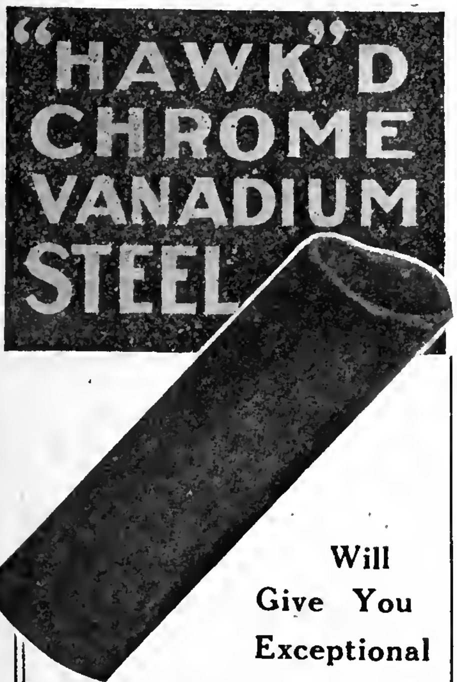
Catalogues

The Terry Steam Turbine Co., Hartford, Conn. have issued an informal booklet describing a combination of auxiliary machinery called the duplex exciter. It is claimed that for nearly all large steam generating stations these duplex exciter sets have shown some striking advantages over any other source of excitation.

Graphite for Cylinder Lubrication is the title of an attractive little booklet dealing with the above interesting subject and issued by the Joseph Dixon Crucible Co., Jersey City, N.J. The booklet tells of graphite lubrication for both steam and gas cylinders and also gives concise facts about lubricators that are made to use graphite alone or with oil.

Wiring Rules.—The seventh edition of "The Wiring Rules of the Institution of Electrical Engineers" has just been issued. The alterations that have been made are largely matters of detail, but the following points may be noted:—The clause relating to gas pipes is strengthened, and combined gas and electric fittings are not to be used. If gas fittings are adapted they must be entirely disconnected from the gas piping. The test for cables has been somewhat modified. A pressure of 1,000 volts for half an hour is stipulated for 250-volt cables, but this is increased to 2,500 volts for 650-volt cables. These grades of cable are defined by the radial thickness of dielectric and the insulation resistance. The testing current is to be alternating at a frequency of 50-100, and the alternator must have an output of not less than 5 kilowatts. Some modification has been made in the specification of flexibles, and bunching in wood casing is allowed to a larger extent. As regards lead-covered conductors, these must be exposed to view; but it is not clear whether this clause covers Henley's special system. Switches having handles projecting from an open slot in the cover are now barred. Definite distinguishing colors are recommended for positive, negative and neutral conductors, and for three-phase conductors.

The Trill Indicator Co., of Corry, Pa., has issued a new 56-page, complete and up-to-date publication on engine indi-



cators and indicating. The book is copiously illustrated and describes in detail the construction and purpose of the several parts of both the outside and enclosed spring types of indicators, including indicator reducing motion. Considerable space is given to discussion and data on indicator springs and full instructions on indicating and interpreting cards from all types of engines, high pressure steam, gas and fuel oil engines, triple-expansion and compound engines and ammonia compressors. Detailed instructions are given on the application and use of the indicator and the planimeter, with easily understandable instruction on the few arithmetical calculations that are necessary. There are 15 pages illustrating and discussing the characteristic diagrams of the several types of engines, including the latest four-valve engines of the new poppet valve type, the Uniflow engine, high compression two-cycle oil engine and the Diesel engine, also a large number of faulty diagrams, illustrating the common faults of engines. A copy of the book will be sent upon request.

Book Reviews

Patent Protection is the title of a book published by Babcock & Sons, Montreal, Que. An alternative title for this publication is Babcock's Book for Inventors. It is an explanatory statement and guide for clients and others interested in Canadian, United States, and Foreign patents, trade marks, copyrights and similar exclusive privileges. The book contains a great deal of useful information for prospective inventors, etc., and will serve as a medium for obtaining information as a preliminary to taking out a patent. It contains 86 pages and is bound in cloth covers.

The Shipping World Year Book, 2,010 pages $7\frac{1}{4}$ in. x $4\frac{1}{2}$ in., edited by Major E. R. Jones, and published from the "Shipping World" offices, London, England. Price 11s. ($2.75) net. The 1916 or thirtieth edition of this year book contains, as in former years, much valuable information for all interested in shipping. It is a very useful publication for shippers and merchants trading in all parts of the world, and is also a very handy book of reference as the information given covers a wide field. The war has of necessity made the compilation of this work no easy task, as it has effected profoundly the commercial and shipping interests everywhere. This circumstance, however, has not detracted materially from the value of the book, as it has been brought up-to-date as far as possible

from available data. The book is arranged in three sections. the first or general section deals principally with matters affecting navigation and shipping contains a digest of merchant shipping acts, alien and factory acts, customs regulations, etc., also numerous tables embodying much valuable information. This section has been revised and some pages rewritten owing to restrictions imposed by the war, while new features have been added to bring the matter up to date. The second section is devoted to a port and harbor directory of the British Isles, the Overseas Dominions and Foreign Countries. The geographical location of each port is given, together with particulars regarding water levels, anchorages, harbor dues, port officials, etc. The third section gives the customs tariffs of all nations brought up-to-date as far as possible under the present conditions. The tariffs of enemy countries have of necessity been left as they were in the 1915 edition, but considerable changes have been made in the Australian tariff, and also in that of the United Kingdom, the latter being entirely a war emergency measure. There is also a new map of the world showing trade routes, ports and coaling stations, etc. The book is of particular value now in view of the proposals which have been made to develop trade within the Empire and with our Allies. It is printed in clear type, has a very complete index, and is bound in substantial green cloth covers.

TRADE WITH BRITAIN

THE following is a return of trade between Great Britain and Canada in the articles mentioned, during May:—

Exports from Canada

	May, 1915. £	May, 1916. £
Wheat	467,955	1,447,994
Wheatmeal	238,852	493,965

The Publisher's Page

A Request to Advertisers

IN order that we may render to our advertisers the best possible service, to insure change of advertisement and to guarantee insertion in any particular issue, it will be necessary to furnish copy much earlier than formerly.

CANADIAN MACHINERY has doubled in size during the past year. Its growth has been phenomenal. The work in connection with its publication has greatly increased. The number of "forms" and the number of press runs has been doubled. Naturally more time is required.

We invite the co-operation of our advertisers and shall appreciate it if copy and cuts are placed in our hands just as far in advance of the date of issue as possible.

Forms close one week in advance of issue, so that in order that proofs may be submitted and returned to us for correction, it will be necessary that copy and cuts be in our possession a full two weeks before the advertisement is scheduled to appear. Two weeks should be the inside limit, to insure the best of attention. Three weeks would be better and four weeks better still.

Copy for front cover advertisements, especially when cuts are to be made, should be supplied at least three weeks in advance.

Advertisers desiring to use larger space than usual will confer a favor if they will advise us as far in advance as possible in order that suitable position may be reserved.

Canadian Machinery & Manufacturing News

143-153 University Avenue, Toronto, Canada

A convenient type of Crawford Sectional Oven largely used by manufacturers turning out Shells up to twenty-eight pounds each.

The method of heating explained in previous issues is the same with all types of Crawford Ovens—no direct flame coming in contact with the material in the oven.

Either city, natural, gasoline or producer gas can be used with either type of oven.

Ovens and trucks built for baking the varnish or finish on any number or size of shells required at a time.

Motor Driven Speed Lathe

This style of motor drive employs a constant speed motor mounted on a plate having an extension arm to support a bearing for the outer end of the motor shaft. The motor plate is fitted to a slide on a shelf which is securely fastened to the back of the lathe bed. The motor plate is moved by means of a screw which tightens or loosens the belt. A four-step cone pulley on the motor shaft is belted to a four-step cone pulley on the spindle. This gives the same speed variation as when a countershaft is used, and by means of various size cones on the motor a wide range of speeds are obtainable.

The lathe spindle is made from high carbon steel, ground to size, and running in self-oiling bronze bearings. The tailstock has screw and lever feed. The bed is crossed-braced and all clamping levers are above the ways.

Starrett Twin Gas Heater

TRADE MARK REG. U.S. PAT. OFF.

THIS HEATER is very efficient in the machine shop, especially in the tool-room, for tempering small tools, melting lead, babbitt, etc., and as a forge for light work. You will also find this heater extremely handy, useful and economical in your home. For laboratory work and wherever a blue-flame burner is required the Starrett Twin Gas Heater has no equal.

Its effectiveness lies in its scientific construction. The gas and air is thoroughly mixed for perfect combustion while passing through the deflectors in base of tubes. The tubes cause the flames to penetrate each other at cross-angles, thus producing an intense heat, free from smoke and with no waste of gas.

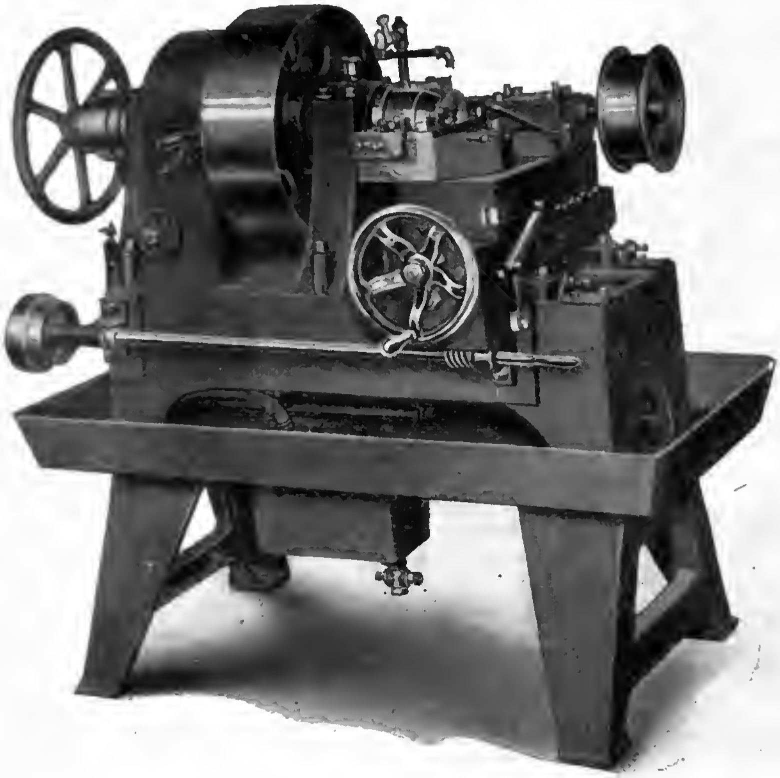
Feeds number, regularly furnished	5
Feeds range	20 to 100
Tail Stock Spindle	3½" dia.
Tail Stock Spindle travel	6"
Width of Bridge	10"
Carriage arranged to take any form of multiple tool holder.	
Bed arranged to take any design of taper attachment, and also for back facing arm.	
All Gears of Steel. High-Speed Gears carbonized and hardened. High-Speed Pinion on pulley shaft is Vanadium Steel, hardened and ground.	
Weight, 10-ft. bed, approximate	6,000 lbs.

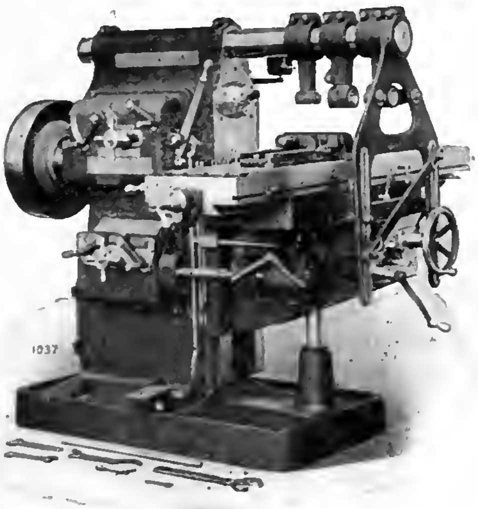
The Duff Manufacturing Co.

ESTABLISHED 1883

Pittsburgh, Pa., U. S. A.

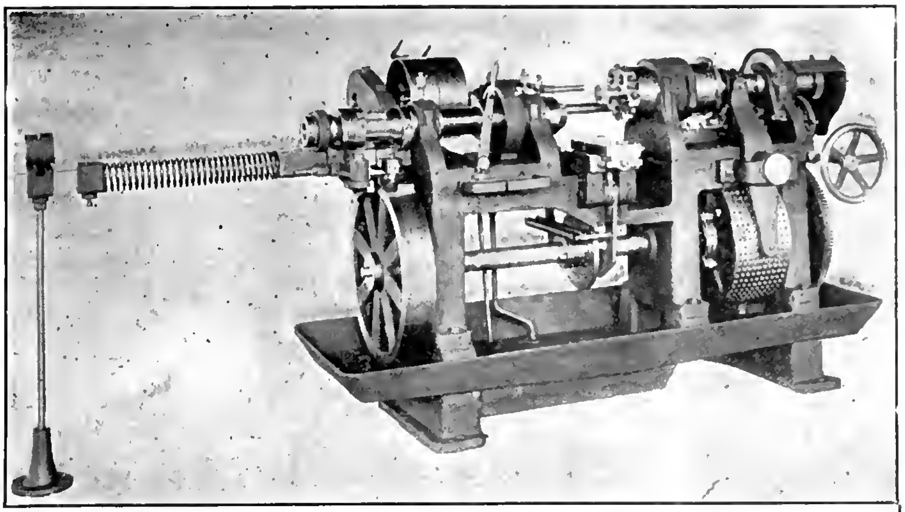
NEW YORK CHICAGO





One of our 9 High Power Single Pulley Plain Millers. We also make 9 cone driven plain machines.

The Chicago Automatic Screw Machine



MANUFACTURES RAPIDLY AND ACCURATELY WITHOUT THE USE OF A COMPLICATED MECHANISM OR A SYSTEM OF CAMS THAT ARE DIFFICULT TO DETERMINE AND ARRANGE ON THE MACHINE. The rigidity of the machine has not been sacrificed for the flexible features which are embodied in the Chicago Automatic. Alignment is correct and there are no parts where excessive wear takes place—therefore accurate production is assured during the long life of the machine.

No countershaft is required—the machine is quipped with a fast and loose pulley on the spindle head, this being the only belt drive on the machine.

Spindle speeds suitable to different sizes and kinds of stock within the capacity of the machine are obtained by changing two gears on the spindle head.

IN LESS THAN SIX WEEKS AFTER YOUR ORDER REACHES US WE CAN PLACE CHICAGOS IN YOUR PLANT READY FOR PRODUCTION.

Chicago Automatic Screw Machines are not an experiment—ten years of intensive manufacture of one product—Automatics—stands behind every machine.

Full particulars on request.

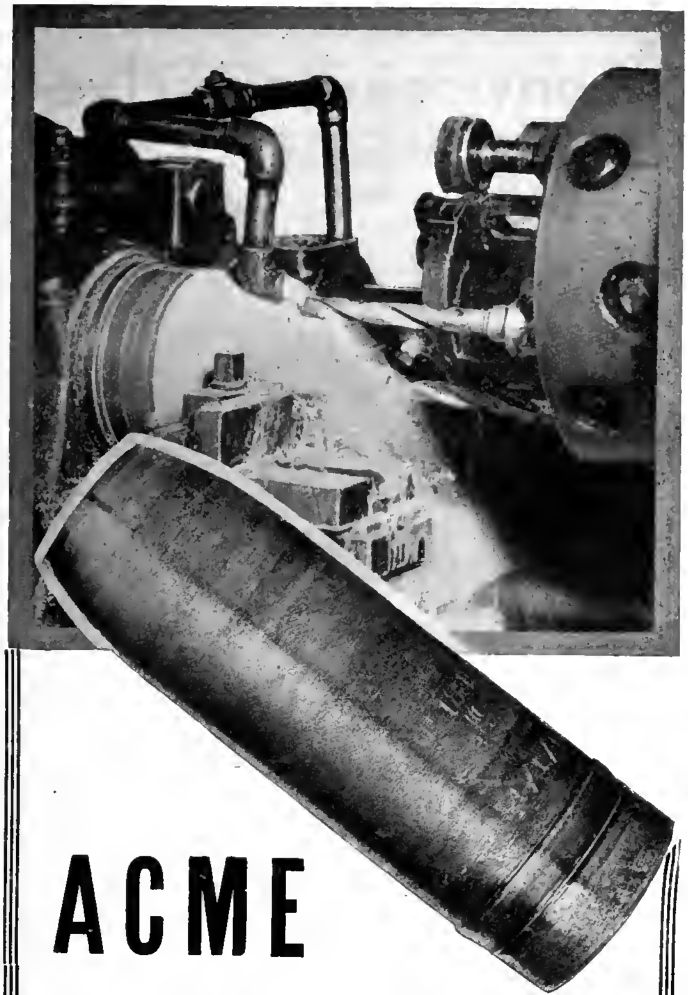
Let us send full Particulars.

HUNTER SAW & MACHINE COMPANY, Pittsburg, Pa.



ACME

Cutting Lubricant used on Shrapnel Shells

Keeps the tools clean and cool and increases production.

"Acme" is a free, unsaponified, animal oil lubricant, which will not separate in solution, gum machines or rust the work.

"Acme" will not clog pipes or stick to the finished work as oil does. Has a clean, wholesome smell.

Leading manufacturers use it on shell work in preference to oil; costs less, increases production.

Use it on your Gear Hobbers, Milling Machines, Turret Lathes and Automatics.

We solicit your trial order and will ship on thirty days' approval, subject to practical test.

Cataract Refining Co., Limited

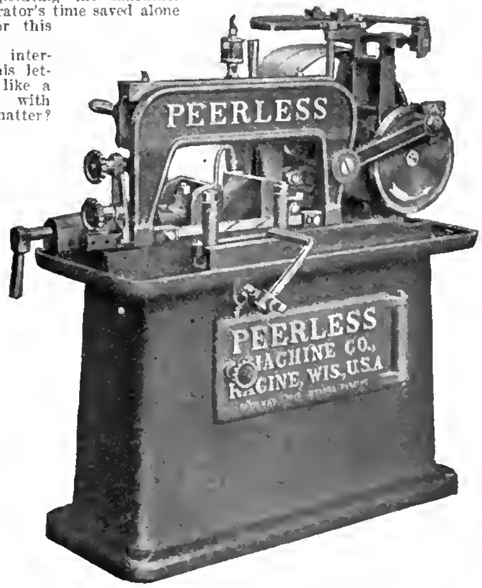
Are You Behind on Cutting Your Steel?

then read these two paragraphs from a customer's letter. Could anyone expect to hear so favorably from a customer after waiting eight weeks for delivery on machine? It was real production and satisfaction that prompted them to write this letter.

"On arrival of this machine we were so far behind on cutting that we thought sure one or two more machines would be required for our works, but owing to the high speed and the rapid cutting of this machine it has caught up with our work in a short time. We are now more than pleased that we had the patience and waited delivery on this tool, even if we were put to considerable inconvenience, as a lot of our work had to be sent out to be cut.

"We must say that this tool is certainly a great time-saver in actual time saved in operating the machine. We figure the operator's time saved alone will soon pay for this tool."

Several other interesting facts in this letter. Would you like a copy, together with other descriptive matter?



This machine cuts off 2¼" round Manganese bronze in 12 seconds. Compare this with your cutting time.

Note its rigid construction, it means increase in production.

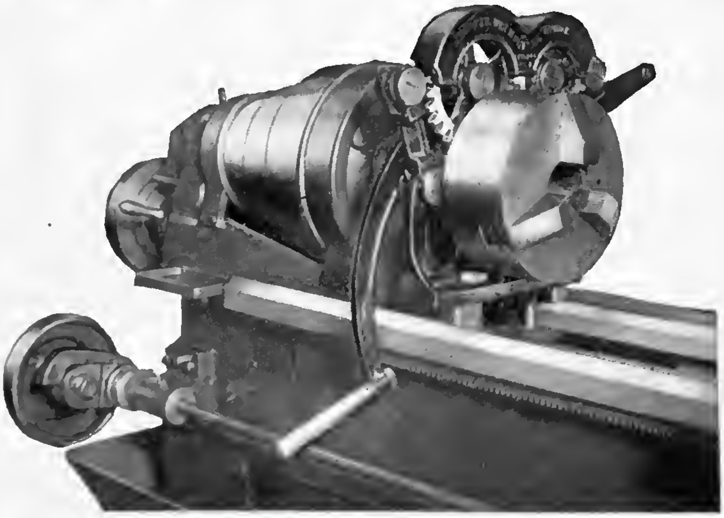
With a Barker Wrenchless Chuck



You don't consider money spent, on something which will bring returns—it is invested.

A chuck which will cut the time of setting-up in half and at the same time not be prohibitive in initial cost or maintenance is a most worth-while investment in your plant —is it not?

Barker Wrenchless Chucks are proving their worth as an investment in many plants where multiple chucking has been a profitless bugaboo—perhaps your neighbor is a Barker fan—let us send you a list of users in your territory.

An inquiry to-day will bring the Barker proposition to you by return mail. You can't go wrong and you do not obligate yourself in any way whatsoever.

The entire opening and closing operation is accomplished with a short action of the hand lever—think what this means in saving of time.

The gas light was a big improvement over the tallow dip, but it had to give way to the electric light; and the Tungsten has superseded the little glimmer that once delighted us.

If you are still employing pipe-cutting methods as antiquated as the tallow dip, you need a Williams Pipe Machine, which occupies the same position in the pipe-cutting field as the Tungsten does in the lighting world, to bring you up-to-date.

Let us quote you prices and terms: any machine to cut 10 sizes of pipe between 1-4 inch and 18 inch, with any kind of power.

Anyone making, selling or buying a pipe machine, claimed to be a Canadian-made Williams Pipe Machine, does so without right or authority from us, and is liable to prosecution for damages.

Greater Production——Less Upkeep

The Landis 1½" Single Head Bolt Cutter, which may be equipped for threading bolts and pipe and tapping nuts, both right and left-hand.

The Landis Die, by virtue of its design, is bound to give a higher production, because the chaser is strictly **tangent** to the stock, thereby **reducing the friction** to a minimum.

The Chaser never requires annealing, hobbing or retempering, but it is simply ground on the end and advanced in its holders. Our customers report that one set of chasers will stand from 90 to 120 grindings, thereby giving the **Landis Chaser** a life from **twenty** to **thirty** times that of any other die—that means small upkeep.

We will be glad to give further particulars—send us your requirements at once.

SIR HENRY IRVING
As Hamlet in "Hamlet, Prince of Denmark"

"To be, or not to be, tha. is the question,
Whether it is nobler in the mind
To suffer the slings and arrows
Of outrageous fortune,
Or to take arms against a sea of troubles"

Often users of Babbitt Metals are confronted with the question

To Be, or Not To Be

It means much to the engineer to get Babbitt Metals of UNIFORM QUALITY.

Our melting pot has a capacity of 35 tons.

This means 35 tons of Babbitt Metal of one uniform quality.

Engineers will avoid "a sea of troubles" if they specify IMPERIAL GENUINE Babbitt Metal for high speed and all bearings carrying extremely heavy loads, and HARRIS HEAVY PRESSURE, "The Babbitt Metal without a fault" for all general machinery bearings.

We guarantee our Babbitt Metals to give EXCELLENT SERVICE.

PULLEYS

No Keys

No Set Screws

In Perfect Balance

Lighter

Stronger

Better Belt Surface

The Dodge Standard Wood Split Pulley

The Wood Split Pulley is better than either cast iron split pulleys or steel split pulleys for the following reasons—

The wood pulley is lighter, stronger, better balanced, and provides a very much better belt surface. It costs 33 1-3% less money and provides 50% more returns in horse-power value. It may be run at very much higher speeds with no danger of bursting—also it may be had quicker and in a greater range of sizes.

It costs less to get—less to put on—and less to keep.

We make approximately 300 Dodge pulleys every day—everybody uses them.

There are more Dodge pulleys making ammunition than any other kind—you can get them quick.

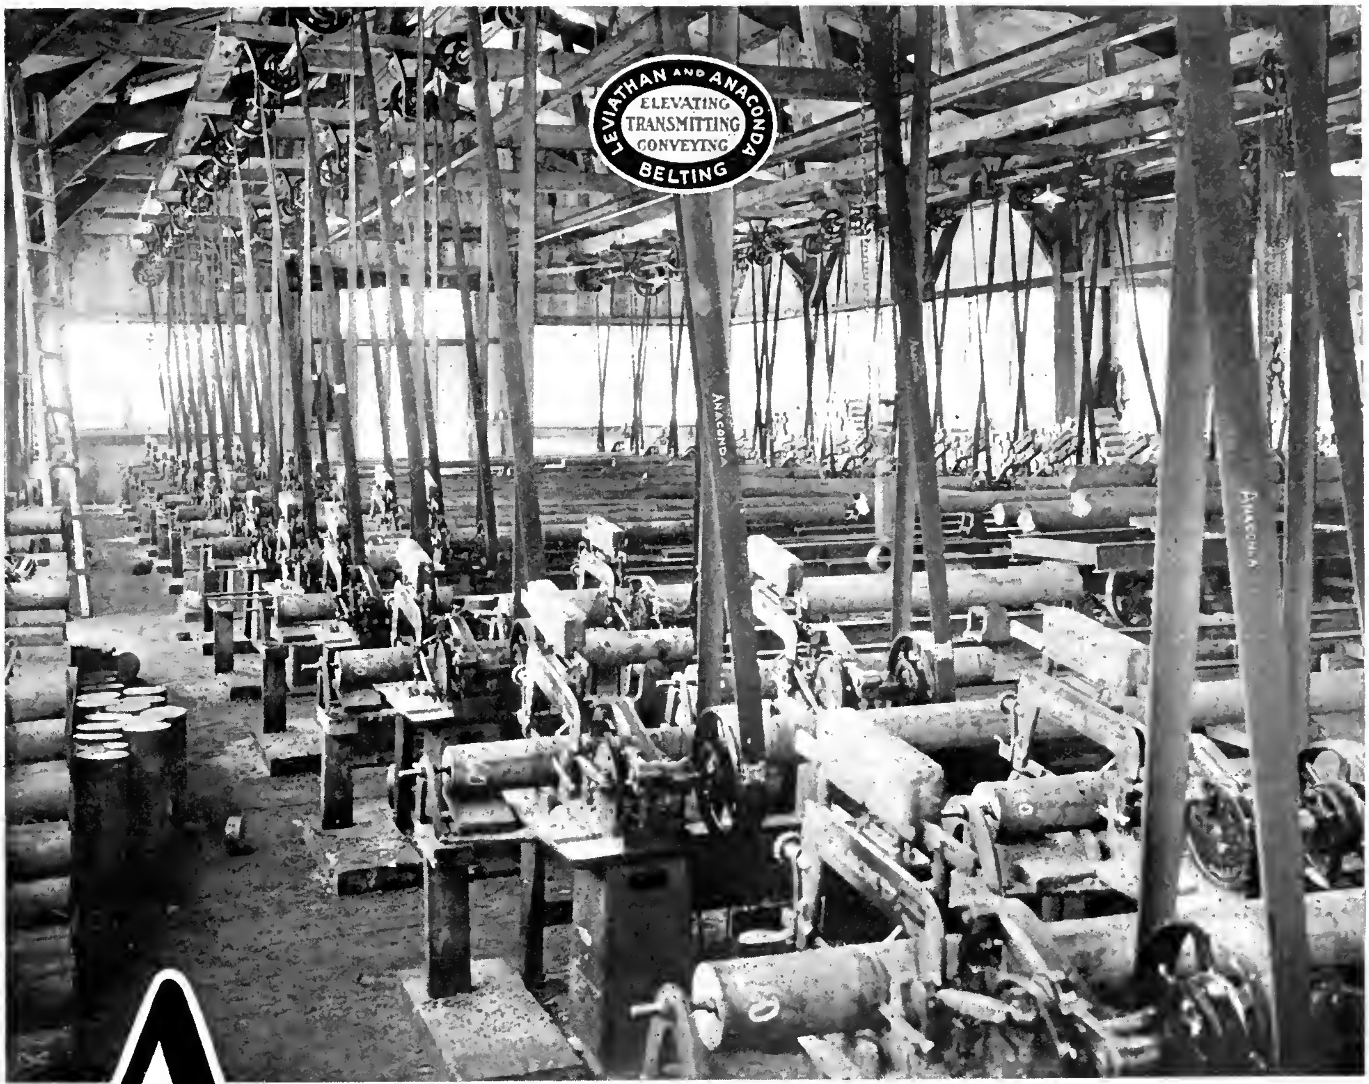
Every pulley is thoroughly nailed. Every pulley is guaranteed for Double Belts.

We are Canada's greatest pulley makers.

If you have not our Books, write us.

DODGE MANUFACTURING COMPANY

Toronto - - Montreal



Anaconda Belting

1800 Feet **2½" 4 Ply**

This is the belt you should be using if you want the largest delivery of power and maximum belt service in driving machines such as Saws, Turret Lathes, Heavy Duty Drills, Grinders, Etc., that use liquid cutting compositions, because it is filled with a composition that makes it heat, oil, water and acid proof.

The saws, as illustrated above, are all "Draw-cut" which means that the strain on the belt is intermittent and if the belts slipped, satisfactory work could not be done.

Anconda Belting possesses unusual wearing qualities, and reduces power loss, repairs, "take-ups" and attention to the minimum. It is of greater general serviceability than any other belt. A trial will convince you.

The initial cost is 50 per cent. less than leather.

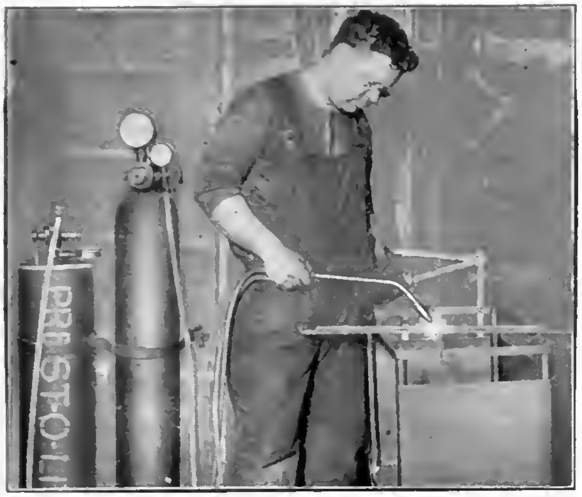
Oxy-Acetylene Welding and Cutting



All-Metal Hospital Furniture Is Made Better by This Process

Many large manufacturers of all-metal hospital furniture are employing oxy-acetylene welding to improve and simplify the finished article, and, at the same time, cut production cost.

Oxy-acetylene welding is less expensive and superior to riveting—provides a better, neater appearing and more lasting joint.

There is practically no line of metal manufacturing or repairing in which oxy-acetylene welding has not already established itself firmly as standard, routine method.

Every desirable feature of oxy-acetylene welding and cutting is provided by the

Prest-O-Lite PROCESS

Employs both gases (acetylene and oxygen) in portable cylinders. Prest-O-Lite Dissolved Acetylene (ready-made carbide gas) is backed by Prest-O-Lite Service, which provides dry, purified gas, insuring better welds, quicker work, and lower cost, and also avoids the large initial outlay and heavy depreciation incurred in making crude acetylene in a carbide generator.

The necessary equipment is not expensive. We furnish high-grade welding apparatus for $75; acetylene service at additional cost. Adaptable for oxy-acetylene cutting by the addition of a special cutting blow pipe. Thorough instructions are furnished free to every user of Prest-O-Lite Dissolved Acetylene—any average workman who understands metals can learn the process quickly and easily.

If you are interested, we will gladly send illustrated literature and interesting data showing actual instances of savings and manufacturing improvements made by others. It may suggest valuable ideas to you in handling similar work. ASK FOR IT.

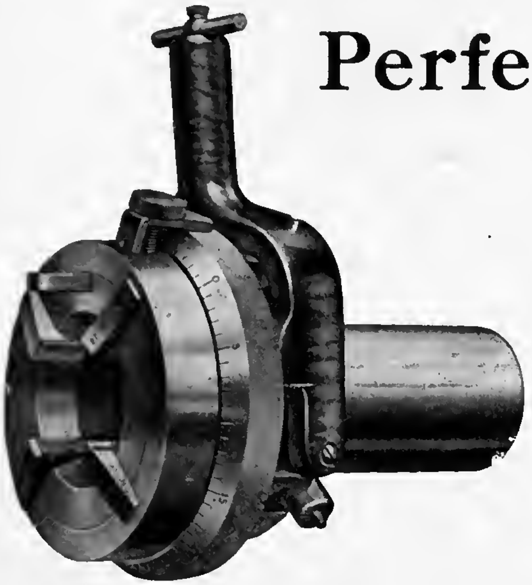
Wells Self-Opening Dies
CUT
Perfect Screw Threads



WELLS SELF-OPENING DIE
has both face and hand trip.

The Wells Self-Opening Die cuts the thread with a fine shearing cut, then opens with a quick, positive snap.

Adaptability

The Wells Self-Opening Die can be used on screw machines, lathes, automatics, drill presses and bolt cutters.

Chaser Principle

The Wells Self-Opening Die embodies an entirely new principle of design. The chasers are about four times as long as the threaded portions and are supported throughout their entire length and width by the solid sides of the slots in the body. They cannot squirm away from the work. Wear is reduced to a minimum throughout. Adjustment is simple, positive and accurate.

A large number of these Dies in Stock for immediate shipment.

Machining and Finishing the 8-inch High Explosive Shell--I

Staff Article

Although the manufacture of the large size high explosive shell by Canadian metal-working plants is now well established, it may be said that its initiation and development progress have occasioned little more than passing interest, the more noticeable of course because of the excitement and enthusiasm aroused when the manufacture of shrapnel shell was instituted. Experience in that direction has made possible the new achievement. The machine tool equipment, methods and devices, described, cover a plant which is easily a front-rank producer.

WHEN many months ago, shell makers in this country realized the fact that large shells would form a considerable, if not the greater portion of munitions output, the problems involved in their manufacture were the subject of considerable discussion. Numerous suggestions were advanced and various systems planned, all of which were influenced by each makers' experience on small and medium shells, and the desire to use existing plant to advantage when possible. Where a shrapnel plant was continuing on that product and starting upon 8 in. as well, the new plant required for the latter size would be equipped with machines selected definitely for it, enabling a greater degree of specialization to be exercised.

The plant with which this article deals changed over from 18 lb. H. E. to 8 in. shells, and in doing so were able to employ a number of their original machines in machining the base plug of the larger shell, while various other items of equipment were utilized as opportunity suggested itself. So well were the plans prepared and so thorough the organization that within —— days of the completion of the last shrapnel shell, 8 in. H. E. shells were being shipped, the rate of output rapidly increasing to the desired maximum.

As received from the makers the forging weighs approximately 290 lbs., the rough dimensions being 26 in. long, 8¾ in. diameter and 4½ in. bore. Finished sizes of the shell with driving band and base plug in position are shown in Fig. 1, the weight of the shell complete as shown being 177 lbs. 2½ oz. with a limit either way of 14 oz. The bursting charge and fuse bring this up to 200 lbs. with a limit either way of 3¼ oz.

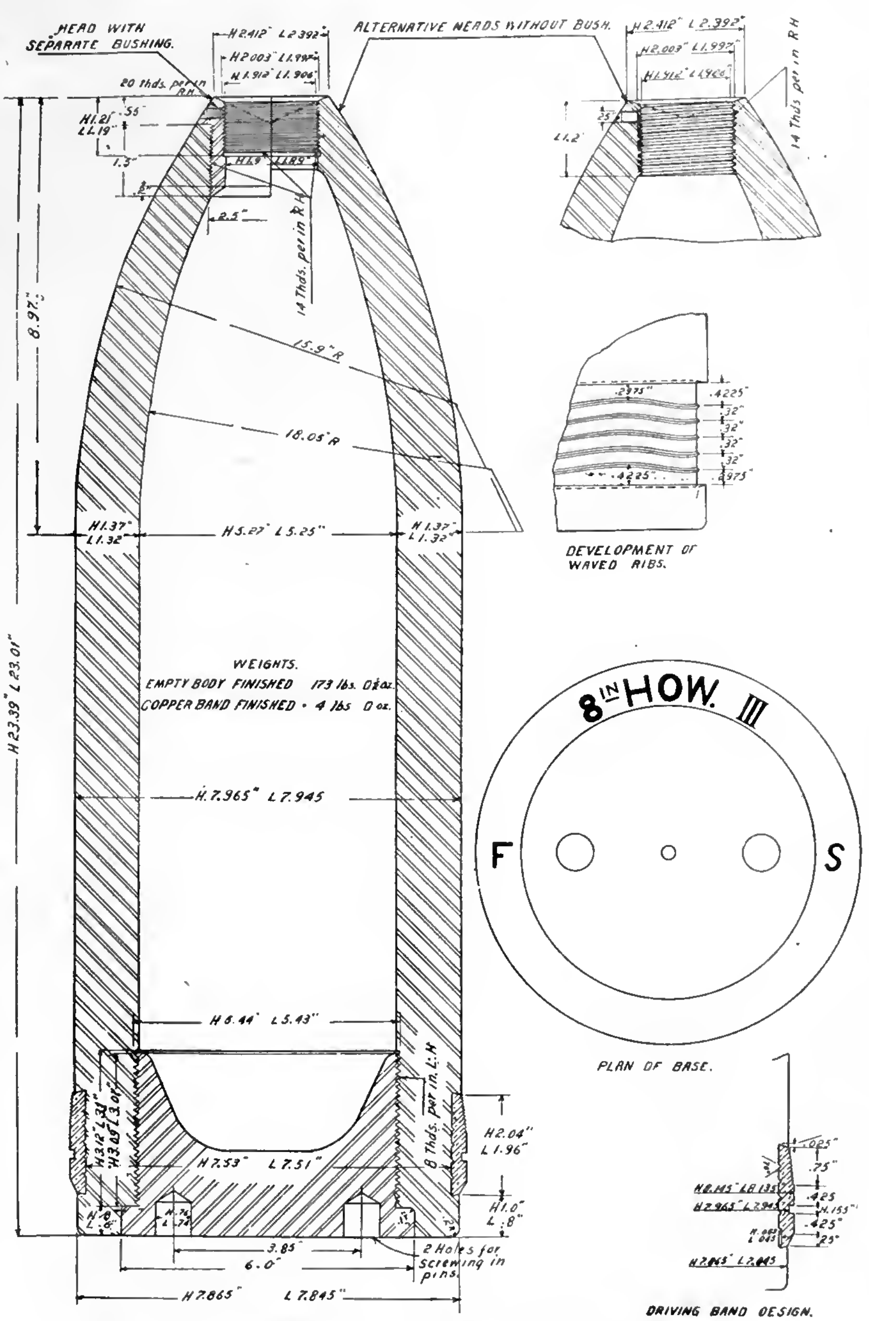

FIG. 1. AN 8-INCH HIGH-EXPLOSIVE SHELL.

Twelve separate and distinct machining operations are performed on the shell either by itself or when assembled with base plug and driving band. A diagrammtic representation of each operation is given in Fig. 4.

A battery of Colburn D2 heavy duty drills is employed on operation 1, two of these machines being illustrated in Fig. 5. A convenient type of lifting clamp and high speed chain blocks enable each operator to handle his own forgings very rapidly without extra help or undue fatigue. The forgings are dropped over a centering arbor mounted on a table, which slides forward so as to enable the forging to hang clear of the machine. The arbor consists of a tubular column containing a plunger supported by a coil spring of suitable size so that when the forging, weighing approximately 290 lbs. rests on the top of the plunger, the spring is compressed to a point which allows the bottom end of the forging to rest on the plate. The three set screws are now tightened to prevent the forging from turning around when the drill is started on top of the nose.

The upward pressure of the spring keeps the plunger wedged tightly in the inside of the nose, and as the plunger is made a close sliding fit in the support-

FIG. 2. RECEIVING DOCK FOR ROUGH FORGINGS.

ing column any wobbling of the nose when the drill is entering is kept within safe limits. The table is secured in its working position by a pin as shown and is moved out by a hand lever seen in Fig. 5.

The hole drilled is 1¾ in. dia., which leaves ample metal for boring out later so as to make this hole true with the main bore. The drill is now removed and a facing cutter with pilot is employed to remove stock till the surface is a definite length from the lower edge of the hole. The travel is regulated to an approximate depth indicated by a mark on the spindle, after which a little hand feeding brings the surface down to a point indicated by a hook gauge which is inserted in the hole and catches on the bottom edge, a mark on gauge indicating if the surface of the nose is machined to the desired amount.

Two cutting off machines made by the Williams Tool Co trim the open end of the shell to the high limit of the over all length, see operation 2, the object of this being to have a reserve of material for adjusting the final weights at a later stage of the operations.

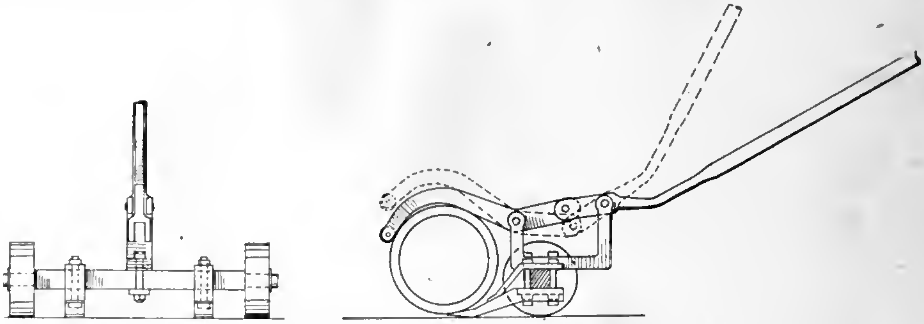

FIG. 3. TROLLEY FOR HANDLING ROUGH FORGINGS.

A careful consideration of boring requirements indicated the advisability of roughing out the inside of the nose so as approximately form the final outline of the interior, as the amount of metal left at this point during forging is in excess of that at other portions of the bore. As it also varies somewhat in forgings from different sources, the certainty of trouble due to the boring tool running into deep metal at the end of the cut was so great, that a separate operation is performed which enables the boring tool to complete its work without readjustment toward the end of its travel. Operation 3 which accomplishes this work is done in 20 in. vertical drill presses. A battery of three Bertram machines handling the work satisfactorily. The forging is inverted, the nose resting on a pilot block and the upper part supported by a rest mounted on the column of the machine. A double bladed profile cutter with flat blades is mounted on the lower end of a bar, and removes the excess metal to

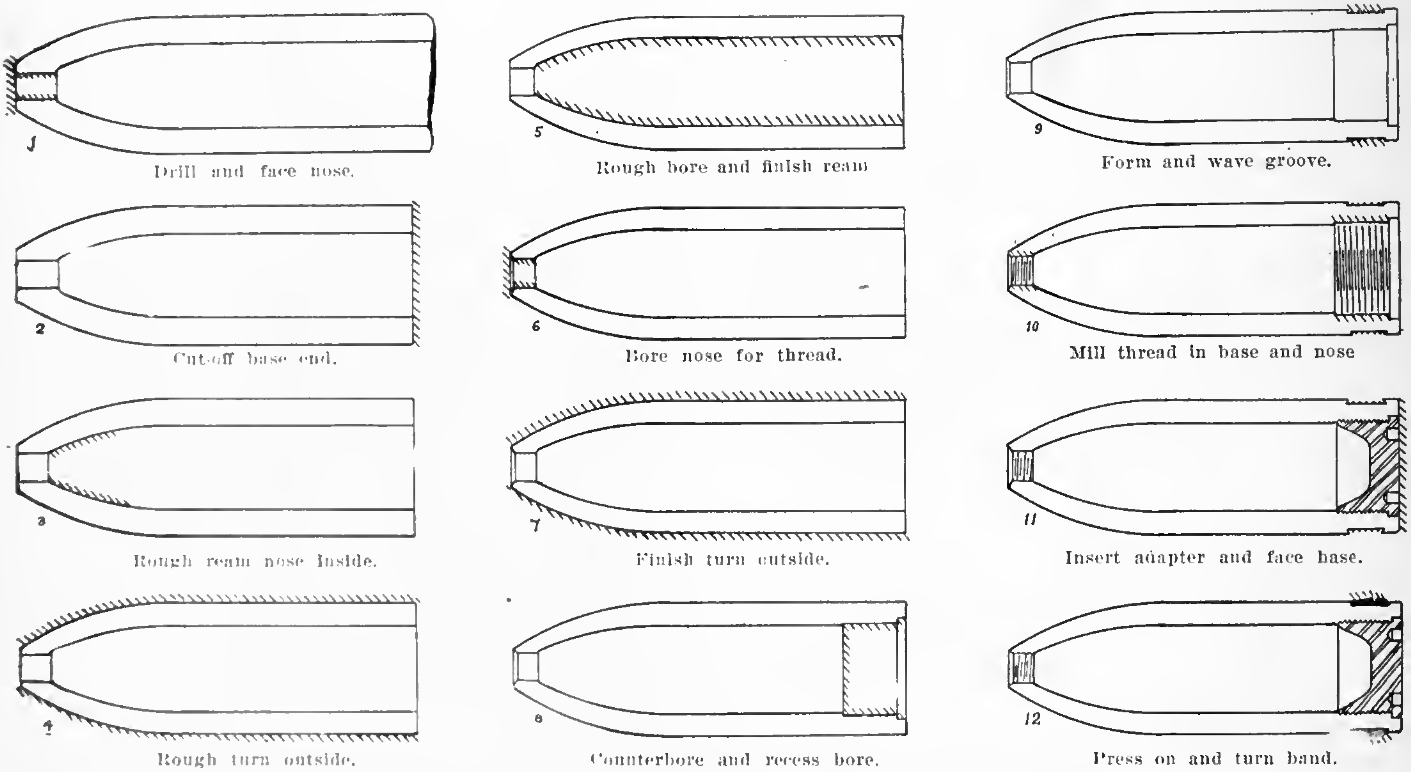

FIG. 4. DIAGRAM ILLUSTRATING SEQUENCE OF MACHINING OPERATIONS.

a predetermined amount. As the shell is resting on a machined surface it allows the use of positive stops on the machine for stopping the feed at a uniform point. As this is a roughing operation only, the cutters are fed by hand

FIG. 5. HEAVY DUTY DRILLING MACHINES PERFORMING INITIAL OPERATIONS ON FORGINGS.

to the limit of capacity, a copious supply of cutting compound being used.

The handling tackle for this machine is suspended from chain blocks running on a overhead rail which allows the work to be picked up and deposited within a considerable radius of the machine.

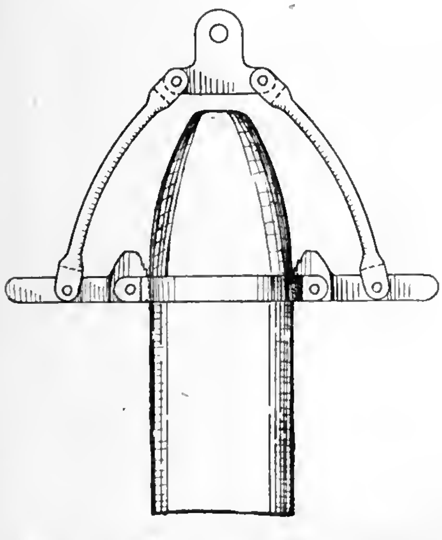

FIG. 6. AUTOMATIC LIFTING CLAMP FOR PLACING FORGINGS ON ARBOR, SHOWN IN FIGS. 5 AND 7.

Preliminary Turning

Rough turning which constitutes operation 4 is the heaviest part of the machine work, and the rate of production possible with high speed cutting tools demands lathes of exceptionally rigid and powerful design. Among the machines engaged on this work are five Canadian Fairbanks, one American Tool Works and one Le Blond, the first being 26 in. and the two latter 30 in. lathes.

When operations were commenced each machine turned the complete length of the forging, profile attachments of conventional design being employed to form the nose. This necessitated mounting the cutting tool at the left side of the tool rest, with the result that the overhang of the tailstock spindle, which was necessary to clear the width of carriage, was excessive allowing the work to yield so that feeds had to be cut down to a point that interfered with production. Part of the lathes therefore were devoted to turning the straight portion of the body and others were retained for forming the nose only, these latter having the cutting tool mounted at the right side of the tool rest, reducing the tailstock overhang to a minimum and permitting the heaviest cuts to be taken right up to the point. This, coupled with exceptionally convenient handling arrangements, resulted in production in excess of that originally calculated on.

Driving and Supporting Work

In all of the machines engaged in this operation the work-holding devices are similar, consisting of a short driving arbor mounted on the spindle, and a pipe centre with a very slight taper which enters the nose end. The driving

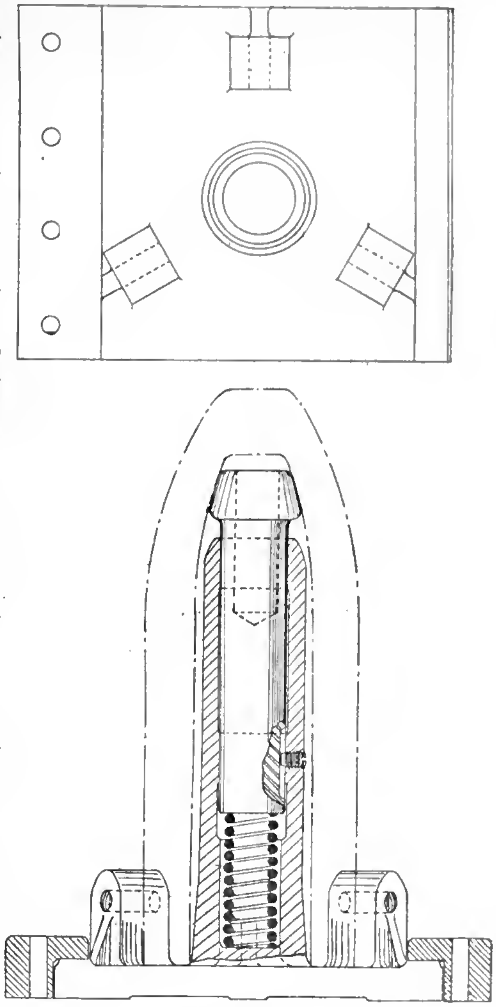

FIG. 7. ARBOR FOR SUPPORTING FORGINGS IN FIG. 4.

arbors are of the expanding dog type and, where the lathe spindle is hollow, they are actuated by a rod and handwheel. Fig. 8 shows an arbor as used, except that a solid spindle prevented the use of a rod as mentioned. To overcome this difficulty the body was cut away on opposite sides to allow access to the

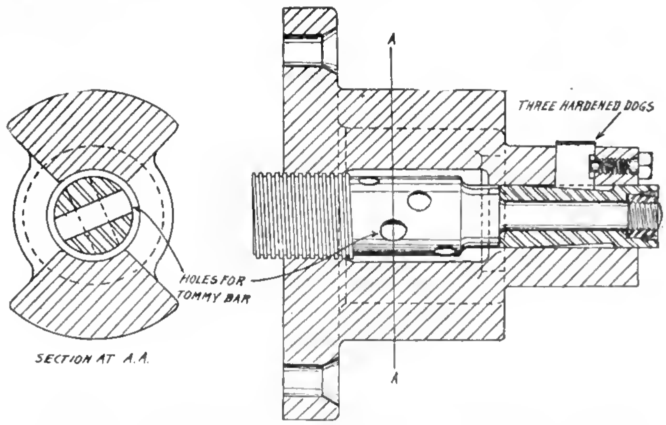

FIG. 8. EXPANDING DRIVING ARBOR USED IN ROUGH TURNING OPERATIONS.

square threaded spindle, which is turned by a tommy bar engaging with the holes shown. The movement of the spindle causes the tapered bushing to travel out-

wards and expand the dogs, these latter being retained in place by screws engaging with a slot in one end of the dog.

Up to this point all of the machine work, with the exception of a cutting off, has been done with reference to the interior surface as a locating base. The result of this is that the rough bore of the borings is sufficiently concentre with the rough turned exterior to insure a practically uniform depth of cut by the boring bar.

Machining the Interior

Boring and reaming, while classed as a single operation, are performed in separate similar machines with slight minor variations in equipment. The type of machine used is shown in Fig. 9, the design which was got out by the plant superintendent being strictly of the single purpose description. The shell is held in a long split sleeve chuck which grips it over the entire length of its straight portion, the interior surface of the chuck being relieved so as to make contact at the ends and prevent any working of the shell as the pressure of the tool travels along. The hollow spindle is large enough in diameter to receive the shell nose which projects inwardly past the chuck. Two speeds are provided by large diameter belt pulleys and suitable intermediate gearing, which transmits power to the spindle through the large spur gear on the rear end. The carriage is of the simplest possible design having a cross slide which carries a revolving turret with one bar. This bar is double ended, the cutting end carrying an inserted tool, and the other or controlling end carrying a roller which engages with a cam slot in the bracket at the end of the bed. This cam slot has a straight portion corresponding to the parallel body of the shell, and a curved portion of the same radius as the curve on the innerside of the nose. As the carriage feeds the cutting end of the bar into the shell, the roller on the controlling end travels in the slot causing the cutting end to follow a similar path.

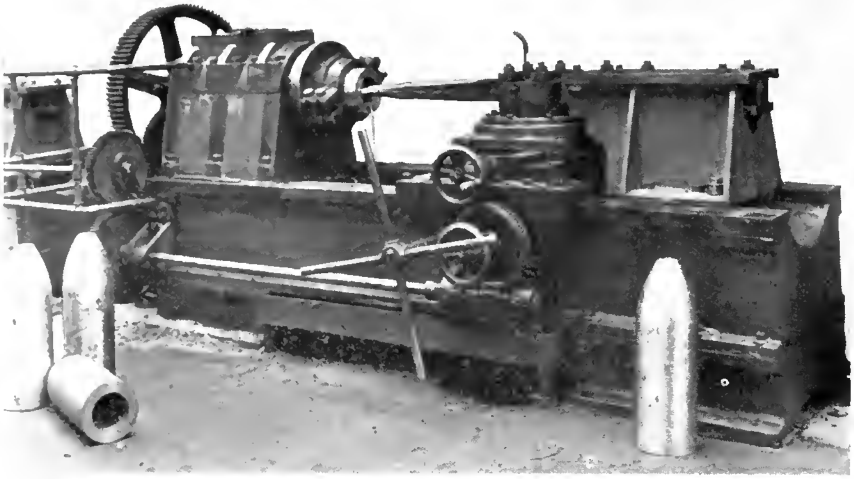

FIG. 9. SHELL-BORING LATHE WITH SWIVELLING BAR CONTROLLED BY PROFILE CAM.

Forming and Finishing the Curved Bore

By making the distances from the centre of turret, to edge of cutting tool and centre of control lever equal to each other, the centre line of the cam slot approximates very closely to the contour of the nose, the variation depending on the distance from the longitudinal centre line of the turret to the edge of the cutting tool. Cutting compound is conveyed through a tube inserted in the side of the bar and delivering it directly on to the cutting tool.

Reaming is excellently performed by machines of the same design in which the bar is controlled by a straight slot. The reaming head is of the double edge inserted-blade type, the blades having oval holes to allow of packing out for regrinding. Ample clearance space is allowed for the passage of chips, this being facilitated by introducing the cutting compound through the back end of the spindle, in liberal volume, which passes through the nose of the shell and obtains proper access to the surface being machined.

Insuring Accuracy of Final Turning

The shell is now provided with a bore of finished surface and accurate dimen-

FIG. 10. VIEW IN BORING DEPARTMENT.

sions and shape. If the hole in the nose be now bored out truly concentric with the bore, the shell can be suitably supported from the inside and finish turned on the outside. To finish bore the nose, the shell is placed on an arbor

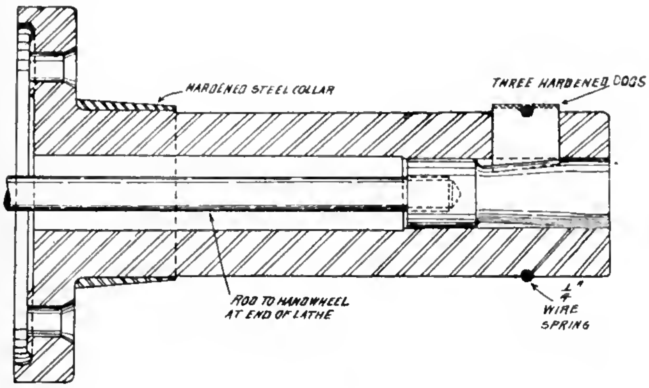

FIG. 11. SELF-CENTERING ARBOR ON WHICH SHELL IS MOUNTED WHEN BORING NOSE.

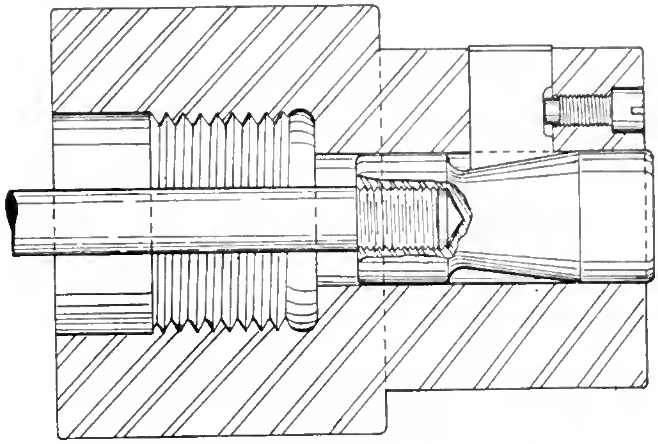

FIG. 13. THREE-DOG EXPANDING DRIVER ADAPTED FOR USE ON SPINDLE NOSE OF FINISHING LATHES.

as shown in Fig. 11. A hardened steel tapered sleeve at the base is made of a suitable size to enter the open base of the shell while three driving dogs at the point are expanded by a taper point on the end of the actuating rod which extends through the hollow spindle to a hand wheel.

A number of Bawden 16 in. lathes are engaged on this operation using the standard type of carriage with suitable tools. The hole is bored out to size ready for having the thread milled at a later stage, and also has the bevel edge formed on the mouth as called for by specification.

Finish Turning Outside of Shell

In finish machining the outside surface, the shell is supported at either end, being driven by the base which is carried on an expanding arbor, while the nose is supported by a pipe center as in operation 4, Fig. 8. This work can be efficiently accomplished on lathes of medium swing, 16 in. to 20 in. swing allowing ample space for former plates and other details of profile attachments which may possibly require space between the work and the carriage. The lathes in use represented a wide variety of design including 4 Bawden 16 in. manufacturing lathes, 2 Milwaukee 16 in. lathes, 1 C.M.C. 20 in. standard engine lathe and 1 Newhaven 18 in. lathe.

INTERESTING AIR LIFT INSTALLATION

THE air lift pumping plant described is installed at the National Transcontinental Railway yards, near the Quebec Bridge. The work was started in September, 1912, forty-three feet of 8-in. wrought iron pipe being driven from the surface to the rock, and from that point a 5-in. bore hole was started. The well was drilled entirely in shale, red and gray alternating. On September 30 a depth of 400 feet had been reached, and a rough pumping test yielded 200 Imperial gallons per hour. At 280, 520 and 700 feet respectively dry crevices were encountered, while at 775 feet water was struck in considerable quantity. The hole was then reamed to a diameter of 8 in., and a subsequent test yielded 3,200 Imperial gallons per hour.

At a depth of 980 feet, another water crevice was opened up, and at a depth of 1,012 feet drilling was discontinued. The whole well was then reamed out to 8 in. diameter. A large plunger pump was used for a 24-hour test, and with 400 ft. of rods in the well a yield of 5,400 Imperial gallons per hour was maintained. This pump was afterwards operated for eight days to clean out the well, and a sample of water was analyzed and re-

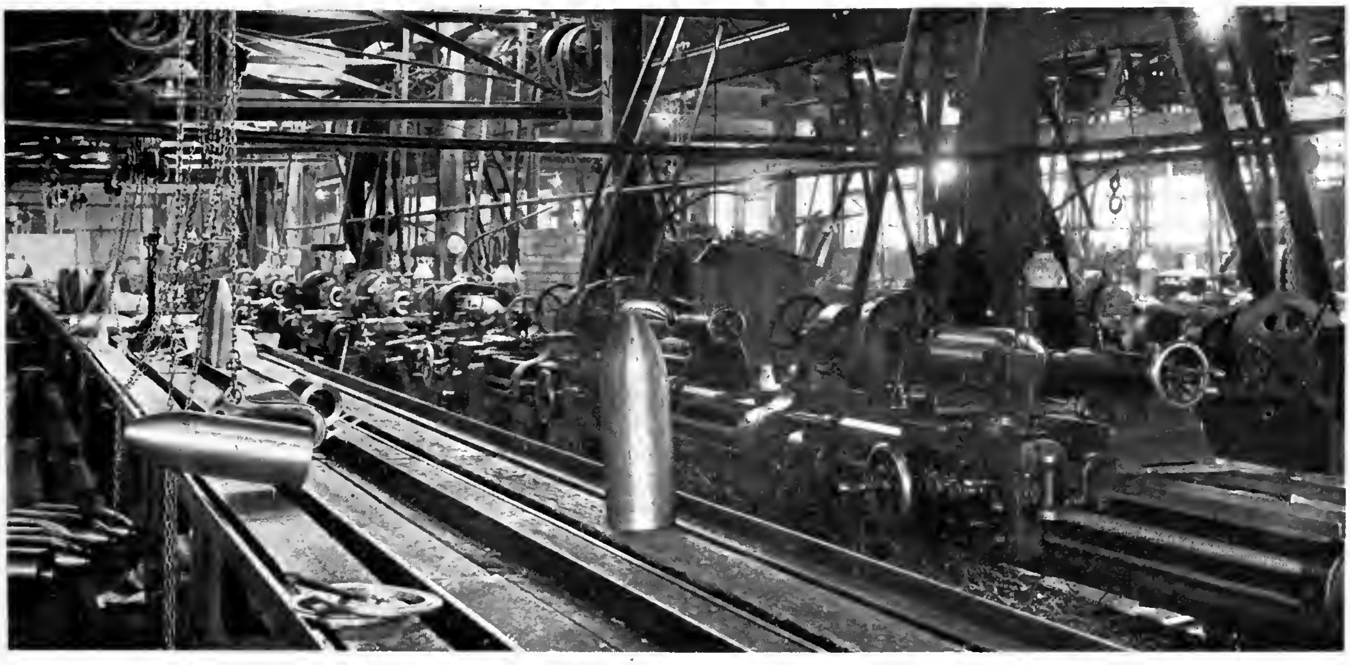

FIG. 12. VIEW IN FINISH TURNING DEPARTMENT.

ported satisfactory for both boiler and domestic purposes. When the well is not being pumped, water rises to the surface; but when being pumped to capacity it drops to a depth of 400 ft. from the surface.

A joint contract was awarded to the Canadian Ingersoll-Rand Co. and Williams & Wilson, of Montreal, for furnishing and installing a suitable pumping plant, the air-lift system being finally adopted because of its lack of moving or wearing parts in the water, and because the air-compressor could be located any distance away from the well.

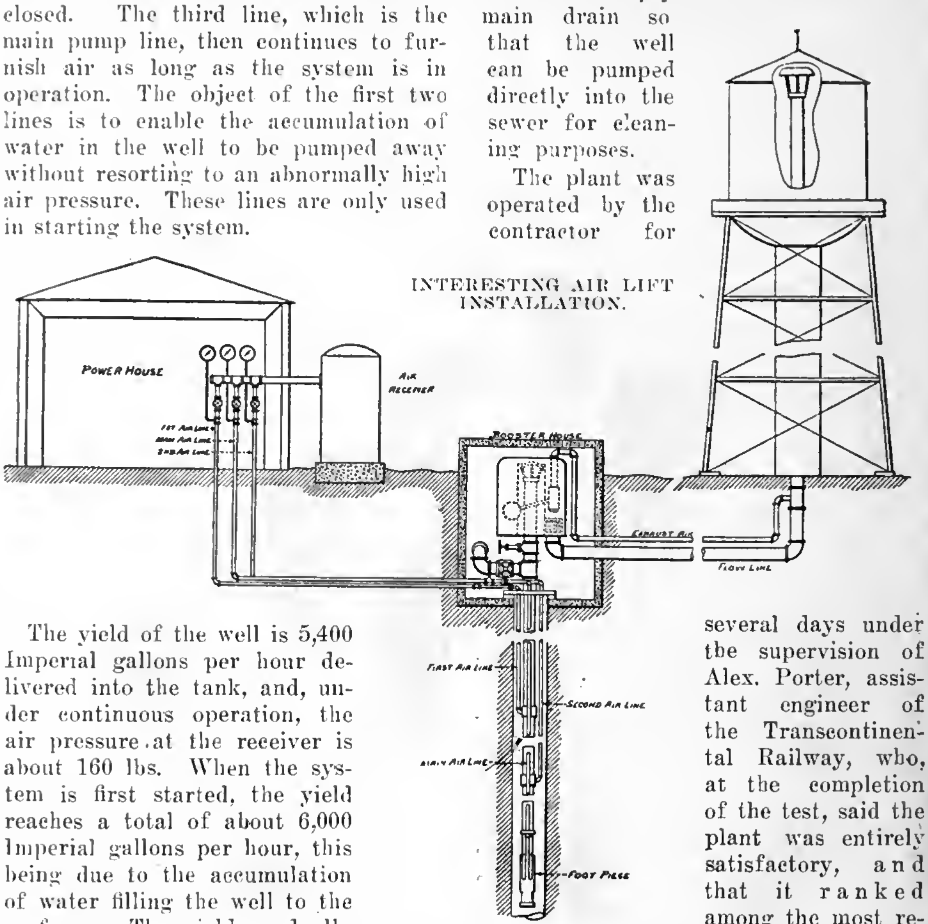
The air-compressor is a Canadian Ingersoll-Rand tandem compound, steam-driven machine, designed for a terminal pressure of 250 pounds, the air cylinders being fitted with a new type of valve known as the Cir-co-leaf valve, which is claimed to be absolutely noiseless in operation. The frame is fully enclosed, and the moving parts work in a constant flood of oil. A combined speed and pressure governor controls the compressor.

The air-lift foot-piece was manufactured by the Harris Air Pump Co., of Indianapolis, whose pumps are extensively installed throughout Canada. The column of water is carried by an air-jet situated below a choker, which arrangement eliminates slippage and causes the air to be distributed through the water in small bubbles. The booster pump was also furnished by the same firm.

Water is discharged into a steel tank 24 feet in diameter, and the total capacity, including the leg, is 61,170 Imperial gallons. The level of the water in feet is indicated by a register on the outside of the tank, by which means it is possible to accurately gauge the capacity of the plant. The tank is supported by a steel frame resting on a concrete base, in which are located the valves and connections to the service mains and to the main drain. Steam is furnished to the compressor at 110 lbs. pressure.

Owing to the depth to which the water drops in the well, three air lines are used, two being tapped into the water discharge line at different depths, and the third entering the Harris foot-piece. Each of these three air lines is controlled by a gate-valve in the power-house, the engineer operating the system without going near the well, which is 250 ft. from the power-house. A gauge over each line shows the pressure and indicates the fall of the water in the well.

Air discharges from the compressor into a high-pressure air-receiver and there to the well. The first air line starts the water flowing and continues to pump until the well lowers as far as this line is capable of lowering it. Then the first air line is gradually turned off until the second line begins to act. When this line has lowered the water as far as it is capable of doing so, the work is taken up by the third line and the second line closed. The third line, which is the main pump line, then continues to furnish air as long as the system is in operation. The object of the first two lines is to enable the accumulation of water in the well to be pumped away without resorting to an abnormally high air pressure. These lines are only used in starting the system.



INTERESTING AIR LIFT INSTALLATION.

The yield of the well is 5,400 Imperial gallons per hour delivered into the tank, and, under continuous operation, the air pressure at the receiver is about 160 lbs. When the system is first started, the yield reaches a total of about 6,000 Imperial gallons per hour, this being due to the accumulation of water filling the well to the surface. The yield gradually decreases under continuous operation until the normal capacity and pumping head are reached.

At the surface the water has to be pumped horizontally a distance of 60 ft., and subsequently to a height of 90 ft. into the top of the steel tank. For this work a Harris booster operates in conjunction with the air-lift. This booster consists of a steel tank resting on the top of the well-casing and receiving the water as it discharges from the well. The operating parts consist of a float and valve located inside the tank. The water and air are separated in this tank, the air rising to the top and maintaining sufficient pressure to force the water to the elevated tank. As the solid column of water discharges, the float drops, allowing the surplus air to exhaust from the tank. This whole operation requires only a few seconds, as a discharge takes place every time the booster is about two-thirds full. In fact, practically a constant flow is maintained.

The surplus air may be piped back to the compressor intake or discharged into the vertical riser to lighten the column of water and reduce the operating pressure. This latter plan was followed in the case of the plant at Quebec. The booster is automatic in operation and requires no attention. It also operates without noise. This apparatus is located in a concrete sump below the ground and is reached through a door in the roof. A by-pass is connected to the main drain so that the well can be pumped directly into the sewer for cleaning purposes.

The plant was operated by the contractor for several days under the supervision of Alex. Porter, assistant engineer of the Transcontinental Railway, who, at the completion of the test, said the plant was entirely satisfactory, and that it ranked among the most reliable of the various railway divisional pumping units. The high lift is a noticeable feature, amounting as it does to about 500 ft. vertically and 60 ft. horizontally. It demonstrates as far as it goes that there is practically no limit to the height to which the air lift will raise water if a fair amount of submergence is obtainable.

On a test recently made the plant pumped nearly 6,000 Imperial gallons per hour; but, as already stated, this capacity was due to accumulated water, and was, of course, only temporary. The normal capacity, 5,000 Imperial gallons per hour, was developed continuously after the level dropped to 400 ft., at which point the running pressure was 160 lbs. per sq. in.—Compressed Air Magazine.

T. E. Lewis, a British inventor, has patented an engine which he claims incorporates an entirely new principle. It is stated that this new engine retains its efficiency unimpaired in the case of gas, steam, oil, petrol, or air, and can be made a rotary or stationary type. It dispenses altogether with the use of cranks and connecting rods, while the speed attained and the regularity of movement are said to be phenomenal.

Canadian Shipbuilding and a Canadian Merchant Marine

By Col. Thomas Cantley *

The accompanying article embodies the substance of an address delivered at the recent Canadian Manufacturers' Association Convention in Hamilton. It is noteworthy because of its intelligent discussion of the dual subject of "Canadian Shipbuilding" and a "Canadian-owned Merchant Marine." The reasoning adduced is that derivable only from a broad, personal outlook and from a close personal study of past and present records of commercial and maritime countries. In the data given, there are not only all the elements constituting a stirring appeal for national action, but a wealth of educative matter that will rally support for the latter accomplishment with the least possible delay and the greatest effectiveness.

PERHAPS no enterprise, manufacturing or otherwise, is more vital to the Dominion of Canada today, and will become more so at the close of the war, than that of a well developed shipbuilding industry sufficient to meet fully our export requirements of agricultural, timber, mining and manufactured products. Our experience during the last year and a half should waken us to the danger that we run and the homage that we pay by dependence on foreign or other than Canadian ocean transport.

Our Atlantic Port Advantages

Our mail service has been interrupted, delayed and in a general way is poorer and less efficient than it was a generation ago. This is owing largely, of course, to so many British passenger liners being requisitioned by the Admiralty, but intensified by the fact that the passenger traffic of the Atlantic has been largely monopolized by the port of New York, notwithstanding the fact that Halifax, as recent events has amply proved, is an all-important national port from both a military and naval standpoint. It is ice-free, the safest on the whole Atlantic seaboard, the most commodious, the most certain and easy of approach, nearer to Southampton than is New York by about 680 miles, and 580 miles nearer to Liverpool—the shortened distance being an economic advantage of no small moment in these days of 40,000 and 50,000 ton, and 20 to 24-knot Atlantic liners. The shorter sea voyage means a saving of time to passengers, and is an all important matter as regards express freight and perishable commodities.

Our Resources Export Possibilities

If a free pathway across the seas is the first condition of the Empire's existence, as our Premier a few months ago so tersely told us, then it naturally follows that a national service of ships, both passenger and freight, to use this pathway is next in importance. Surely, then, it is time that both Canada and Great Britain became independent of foreign ports for the handling of its passenger, mail and freight traffic. In Canadian bottoms should be carried the product of this Dominion, and there should also be provided the ferry for bringing to our shores the enormous immigration which after the war will be lured to Canada by its wide diversity of opportunities.

Of the latter, mention may be made of the fishing possibilities, mining and timber resources of the Maritime Provinces; the market and truck garden possibilities of the Eastern Townships and other portions of Quebec, the stock-raising, and manufacturing possibilities of Ontario, the illimitable wheat fields of the Great Canadian West, and the mining, lumbering and fishing possibilities of British Columbia. The expansion of the Dominion from these and other sources must needs call for an ever increasing mercantile marine service. The export and import trade to and from the British Empire, our present Allies, and neutral nations of not only Europe, but the Orient, opens up a boundless prospect of big foreign business.

Our Foreign Shipping Dependence

Looking backward, it is perhaps difficult to understand why the Mother Country, and the Dominions composing the Empire, have for years been content to rely to so large an extent on Germany and the Scandinavian countries, for the transport of their passengers, mails, agricultural and manufactured products, and by so doing have thus played into the hands of their enemies and competitors. It may be said that this is one of the "after-the-war" problems—but even so it should nevertheless be tackled now. An efficient mercantile marine commensurate with Canada's requirements cannot be built in a day, or indeed in a decade, and it behoves us in Canada to view the situation fairly, meet the issue squarely and deal with it effectively.

U. S. Shipbuilding Growth and Decline

Perhaps at this point a short resumé of the growth and decline of the shipbuilding industry in the United States may be helpful in formulating a policy which we in Canada might adopt, looking to the fostering, growth and upbuilding of a strong, virile, shipbuilding and ship-owning industry. In looking into the experiences of our neighbors, we find that since 1789 the home trade of the United States on ocean, lake and river has been reserved for American vessels, and under this policy their coastwise tonnage had increased from 68,607 tons in 1789 to 6,852,536 tons in 1914. This, however, applies only to the home trade of the United States, as with the shipping registered for trade overseas it is very different.

U. S. Shipping Aids Granted

The first aid given American shipping was in 1789 when a discount of 10 per cent. was allowed off the Customs duty on all goods imported in ships built and owned by American citizens, and later a further Customs discount was granted on specific articles. In 1794 this aid was changed in form, but not in principle—the discount being abolished, but a surtax of 10 per cent. was added to the duty on all goods carried to the United States in foreign ships. As a result of these preferences, American tonnage registered for overseas commerce increased from 123,893 tons in 1789 to 411,438 tons in 1792. In 1800 this tonnage had further increased to 667,107 tons, and in 1810 to 981,019 tons. Thus national encouragement of the industry had quickly produced a growth and efficiency rather remarkable.

U. S. Shipping Aids Withdrawn

In 1815 the United States withdrew its surtax duties as against British ships in direct trade with the United Kingdom. Commercial treaties were entered into with Britain and other foreign Governments between 1815 and 1850 whereby ships of either nation were admitted on terms of equality into the ports of the other, so far as tariff and tonnage duties were concerned. In other words, the encouragement or preference given United States shipping in the early years of the American Republic was abandoned.

Further, about this time pressure was brought to bear on the American Government from the inland and agricultural sections of the country to withdraw the shipping aid and preference. This short-sighted, narrow, sectional and mistakenly selfish policy was effective, although the merchants and shipowners

*President, Nova Scotia Steel & Coal Co., and Canadian Manufacturers' Association.

who understood the situation protested strongly against such action. Notwithstanding the above, American shipping continued to grow slowly until 1850, the registered tonnage then being 1,435,694 tons, carrying 72.5 per cent. of the American overseas trade. Up to this time, of course, the competition had principally been in wooden ships. Steamboats were, however, gradually coming into use. Fulton created an efficient steam propelled vessel in 1807, but it was not until 1830 that steam vessels appeared in the American coasting trade. Iron ships were built at Bangor, Maine, in 1844 for the New England coast service.

British Subsidies

It was during this period that Great Britain invoked a new form of mercantile marine encouragement. In 1834 a subsidy of $85,000 a year was given to a British steamship company plying steam packets to Rotterdam and Hamburg, and another subsidy of $150,000 to a packet service to Gibraltar. This form of assistance was found to be so valuable in their influence on the then new art of steamship and engine building in the United Kingdom that in 1838 the British Government offered a large subsidy for a steamship service across the North Atlantic. In 1839 Sir Samuel Cunard secured a subsidy of $425,000 a year for a steam line from Liverpool to Halifax and Boston. This, it is understood, amounted to about 25 per cent. per annum on the cost of running the Cunard Line, and was given with the plain intention of establishing firmly in English hands the trans-Atlantic traffic. Other British shipping firms also secured subsidies for lines to South America and to the East Indies, and in a few years British subsidies totalled from three to four million dollars annually.

American Subsidies—Collins Line

For a time the American Government met British subsidy with subsidy. As an offset to the Cunard subsidized line, the American Government in 1847 concluded an agreement with the Collins line of trans-Atlantic steamers for a subsidy of $385,000 a year. When, later, the Collins Company built steamships larger than those of the Cunard, this subsidy was increased to $858,000 a year—the Cunard Company at the same time receiving $856,000 annually from the British Government. Under the impulse of these mail subsidies, American ocean steam shipping rose from 16,068 tons in 1848 to 115,045 tons in 1855.

Decline of American Shipping

Unfortunately for the American shipowners this beneficial policy on the part of the American Government was not continued. It has often been asserted that the decline in American ocean shipping began with the Civil War in 1861. This, however, is only a very superficial view, as the Civil War was only an incident in the decline. In 1855, or six years before the war, shipbuilding in the United States fell from 583,450 tons in that year to 156,602 in 1859. The causes of the decline were in part economic, but in much larger part political. In 1856 the American Government reduced the Collins mail subsidy from $856,000 to $385,000 (the Cunard line were then receiving $856,000). In spite of this drastic reduction the Collins line continued in the service, but the British competition was too keen, and they were forced to quit the field.

Just here it might be noted that in 1860-61, when the American Government were withdrawing assistance from their shipping, Great Britain was expending $1,537,223 in the encouragement of steamship building and mail communication with all parts of the world. France, following the British example, in 1858 offered subsidies of $620,000 a year for a line from Havre to New York, and further large amounts for other lines. About the same time Germany began to subsidize the North German Lloyd on the routes from which the American merchant ships had disappeared.

For a short time after the Civil War, American ocean shipping actually increased, the registered tonnage in 1867 being 1,515,648 tons. It remained at about the same figures for a decade thereafter, but in this same period the proportion of American imports and exports carried in American vessels decreased from 33 to 26 per cent. In 1898 the registered tonnage had fallen to 726,213 tons, or less than half of what it was 31 years previously, and the proportionate carrying capacity to 8 per cent. From 1898 there was a gradual yearly increase, and in 1914, at the outbreak of the great war, this tonnage totalled 1,066,288 tons, although still carrying only about 8 per cent. of the American imports and exports.

In 1891 the U. S. Congress passed the Ocean Mail Act, providing subsidies for postal lines, and, while the subsidies paid under this Act have not been large, totalling in 1914 $1,039,360, of which $673,998 was received by the American Transatlantic service, this aid has proven to be of substantial value to the American mercantile marine.

Panama Canal Act

The Panama Canal Act of 1912 changed the traditional policy of the United States by offering free registry for the overseas trade to American-owned foreign-built vessels not more than five years old. This policy up to 1914 had not been successful. Shortly after the outbreak of the present war, in August, 1914, the U. S. Congress passed an amending Act whereby American-owned foreign-built vessels could be admitted to American registry irrespective of age. At the same time the President was authorized to suspend the requirements of law that the officers of foreign-built vessels should be American citizens, and to exempt the ships in question from compliance with American inspection and measurement laws and regulations. Even this has not had the desired effect.

Comparative Wages Paid

The wide difference in wages and maintenance between American and foreign vessels is one of the chief difficulties encountered, and this is clearly illustrated in the following table, which details the comparative wages in 1914 on American and British cargo steamships of about 5,000 tons capacity:

	American. Wages per month.	British. Wages per month.
Master	$179	$100.00
First officer	90	63.18
Second officer	70	43.74
Third officer	60	....
Carpenter	40	31.59
Boatswain	35	29.16
Quartermasters	35	....
Sailors	30	24.30
Chief engineer	150	97.20
First assistant engineer	100	68.04
Second assistant engineer	90	48.60
Third assistant engineer	80	....
Oilers	40	....
Donkey men	40	32.50
Firemen	35	29.16
Coal passers	30	....
Steward	60	38.88
Cook	45	34.02
Messmen	20	15.00
Cabin boy	20	....

Total American crew, 32 men. Total British crew, 27 men.

Total American payroll per month .... $1,655 Total British payroll per month $994.66

Undoubtedly wages have increased rapidly during the last two years, but the proportion is still about as above. To meet the higher cost of operation and maintenance it has been recommended to the American Government that graded subsidies be granted sufficient to offset the difference in cost of operation between American and foreign vessels, with the condition that these vessels should be so constructed as to render efficient service as transports, etc., in time of war.

Foreign Subsidies

In the fiscal year 1914, the United States paid as subsidies to American steamers under contract the sum of $1,089,361. The following table gives a summary of the amounts paid by way of subsidies, mail pay, bounties and other means to the mercantile marine of the European nations. The figures are for 1909, being the latest officially available:

British Empire	$9,689,384
France	13,423,737
Japan	5,413,700
Italy	3,872,917
Spain	3,150,021
Austria-Hungary	2,984,530
Germany	2,301,029
Russia	1,878,328
Norway	1,102,143
Netherlands	880,011
Sweden	277,752
Denmark	145,000
Belgium	55,970
Portugal	50,000

The growth of German shipbuilding was brought about by application to it of the general protective system of the country, and partly by liberal subsidies. As a result, within 25 years the net tonnage of the ships registered in the two ports of Bremen and Hamburg had increased from less than 230,000 tons to nearly 2,000,000 tons. In addition to subsidies, Germany grants preferential rates on her State railways on cargoes to be carried in German ships.

France ten years ago established a shipbuilding bounty equivalent to $28 per gross ton for steel steamers, this rate being subjected to a gradual reduction of roughly $1 per ton yearly—the present bounty paid being $19.50 per ton.

In Austria a bounty of $8 per gross ton is paid on all steel steamers constructed in that country.

The steel shipbuilding bounty paid in one year in France exceeded $2,000,000; Japan the same year paid total bounties of $997,700; Italy, $886,266; and Austria-Hungary, $850,000.

Largely as a result of the special aid given the shipbuilding industry by the different maritime nations, the growth of the various merchant fleets has been remarkable. The following table from the records of Lloyd's Register for the years 1895 and 1915 illustrates this growth:

	1895. Tons.	1915. Tons.
Great Britain	13,242,630	21,045,049
United States	2,164,763	5,388,194
Austria	394,970	1,055,719
Denmark	356,714	820,181
Holland	446,861	1,496,455
France	1,094,752	8,319,438
Germany	1,886,312	5,439,296
Italy	778,941	1,668,296
Japan	301,101	1,768,386
Norway	1,650,012	2,304,726
Russia	487,681	2,658,628
Spain	554,238	1,095,828
Sweden	497,577	1,118,086
Canada (1894 to 1914)	868,624	932,422

British Columbia Marine

British Columbia has already taken a forward step in the development of a mercantile marine by the introduction in the local Legislature of a bill to encourage the building and operating of British Columbia ocean carriers. This measure provides for the lending of 55 per cent. of the cost upon vessels hereafter built in the province and used exclusively in carrying products to and from British Columbia ports. The loan shall not be for more than 55 per cent. of the ascertained value of the vessel, construction of which shall be commenced and completed within twelve months of the coming into force of the Act, the purpose being for the carriage of freights upon ocean routes. Loans are to bear interest at the rate of 6 per cent., payable half-yearly.

In further aid of the shipbuilding industry of the province a subsidy is to go to the owner who actually pays for the construction of ships, or to his assignees who actually operate them, but not to any middleman or promoter, and up to a number not exceeding twenty ships, in ten annual instalments, so computed as to bring the net earnings of the ship up to 15 per cent. on the actual cost, but never more than five dollars a ton dead weight capacity, the initial instalment to be paid in the first year after peace is declared. Shipbuilding plants may be aided by the guarantee of securities for not over 55 per cent. of the actual cost of the plant. A commission is appointed to supervise the administration of the Act.

It is reported that, as a result of this aid, the Wallace Shipyards of North Vancouver have booked orders for the construction of three steel vessels, the hulls to cost about $400,000. The boats are to be used in the lumber carrying trade from British Columbia ports, and are to be built under an interest guarantee of the British Columbia Government.

Suggested Shipbuilding Commission

Some time ago the New York Chamber of Commerce, a very influential body, put forward a scheme which it thought might well be adopted as the shipbuilding policy of the United States, and Sir George E. Foster, Canadian Minister of Trade and Commerce, in discussing the question of ocean transportation in the House of Commons, on April 26, outlined this scheme, and commented on the way it might be applied to the Canadian problem. Sir George Foster's translation is somewhat as follows:—

The Dominion of Canada would appoint a commission, consisting of, say, three members of the Cabinet, whose departments are interested—say, Commerce, Navy and Finance. The Government side of that commission would be the Ministers of these three departments. Add to these a naval instructor and three practical and experienced men in shipping matters, selected by the Government, and you have the commission which would operate in Canada. That commission would have general oversight and direction of the classes of vessels to be built under the scheme, how they should be manned, everything in connection with them, and to the extent that it would be possible, the regulation of the rates as well. The commission would then be empowered to enter into contracts with shipbuilding companies to build according to the plans and regulations laid down in Canadian shipyards, and the shipbuilders would be allowed the difference between the cost of construction in Canada and in European ports, that difference having been carefully ascertained by the commission.

Nature and Duration of Subsidy

The object would be to enable Canadian shipowners to have their ships built in Canada at exactly the same cost as if they had them built in a European plant. If this tonnage could be built in a European plant at a certain percentage per ton cheaper than in Canada, then the subsidy for construction would be that difference in cost, whatever it was, so as to put the Canadian shipowner on

an equality in the after competition with those having ships built in European shipyards. The time to carry this out would be limited to a period of, say, ten years, during which the operation of building would go on.

The commission would then be empowered to enter into contracts with the shipowners, when the ships were built, and to guarantee to the owners the difference in cost of operating the ships under the Canadian flag and under a European flag, that subsidy to continue for the life of the ship. The commission would ascertain the difference in cost of construction and operation and pay that difference alone. In that connection the Government would place at the disposal of the commission the sum of $15,000,000 or $20,000,000, and empower the commission to guarantee the bonds upon the ships built up to 50 per cent. of the value of the ships. Such bonds would be 5 per cent. bonds, and the Government commission would get one-half of 1 per cent. on these bonds returned to its treasury for its work and its supervision.

Such is the plan of assistance outlined by Sir George E. Foster, and, while we think a simpler method would meet the case, we note with pleasure that the matter has had the attention of our hard-working Minister of Trade and Commerce.

Steel shipbuilding can be devoloped on a broad, comprehensive and permanent scale, provided the Government of Canada deals with the matter on broad, statesmanlike and business lines. Ten to fifteen years will be necessary to build up an organization of skilled workmen, possessing the necessary experience to enable us to compete successfully with foreign countries, and during this adolescent period the fostering influence and stimulation of Government protection must be afforded. If ships built outside of Canada, either in Great Britain or in the other overseas Dominions, are to be admitted free to Canadian registry and trading (and we cannot well refuse such), then at least an amount equal to the duty imposed on the material entering into the Canadian-built ships should be returned to the builders.

The Japanese Policy

After consideration of the various policies adopted by practically all civilized nations, it would seem to us that in view of the present situation in Canada, perhaps the system adopted by Japan is that best calculated to meet our needs at the present time. During the twenty years the commercial fleet of Japan has increased from 360,695 tons to something like 1,500,000 tons. Practically all the ocean mail ships acquired by Japan in the last five years have been built at home, and these are vessels of some 8,000 to 13,500 tons cargo capacity. This large increase in tonnage was brought about by a shipbuilding bounty of $10 per ton for steel steamers over one thousand tons gross, and where these were engined with Japanese built machinery $2.50 per indicated horsepower was added to the bounty. The splitting up of the bounty as to hull construction and machinery enabled the Japanese Government to, in effect, give a larger bounty to the faster and higher powered boats necessary for passenger and mail service. Whatever system of encouragement is adopted by bounty or otherwise, should be for a stated period of years, not less than ten and not exceeding fifteen.

Marine Insurance

The next requisite to a successful Canadian shipbuilding and shipowning industry is that of marine insurance. A great deal has been heard in the past half dozen years as to the alleged unfair treatment of Canada by both Lloyd's and the British insurance companies in the matter of St. Lawrence and B. N. A. marine insurance rates, and Canada has had ample and grave reason for dissatisfaction in that connection. The fact is capable of ample demonstration that Norwegian shipping, through their system of mutual marine insurance, which has been in effect for many years, have covered all their risks, including B. N. A. and St. Lawrence trading, with an average premium rate of slightly under five per cent., and this has prevailed not for one year or a few years, but over a period of more than a decade. This rate is approximately one-half that charged a similar type of tonnage when engaged in like traffic by Lloyd's and British marine underwriters on vessels engaged on B. N. A. and St. Lawrence trade.

This difference in the cost of marine hull insurance is practically a profit in itself, and when there is added to it a very great difference in the cost of cargo insurance, as compared with the American Atlantic ports of Portland, Boston, New York, Philadelphia, and Baltimore, these differences run up into really enormous figures. A mutual insurance scheme on lines somewhat similar to that of Norway might be brought about by a marine insurance board or corporation, on which would be represented the Canadian Government, the Shipping Federation, a representative of the combined Boards of Trade of Halifax, St. John, Montreal, Toronto and Winnipeg.

The experience of Norway and other countries who have adopted a mutual system of insurance and the rates of premium, which experience has shown to be necessary over a period of years, might be taken as a basis for a scheme of this character. One essential would be that all steam vessels engaged in the coasting or foreign trade, built to Lloyd's, British Corporation, or Bureau Veritas classification, would be eligible for and compelled to take out marine insurance to the extent of not less than 75 per cent. of the vessel's value—the premium being variable as to age, character and equipment of the ship. All Canadian tonnage could be grouped in, say, three or four scales of classification for insurance purposes. All Government vessels engaged in lighthouse, patrol, and such service to be included.

Harmful Legislation

It is also essential that the shipping interests should not be handicapped by visionary or vexatious legislation affecting the manning or working of our merchant tonnage. The bedevilling influence of American legislation in this connection has perhaps done more than anything else during the last decade to prevent the expansion and successful operation of the American mercantile marine.

Inspection

In the matter of classification and inspection, Canada stands to-day in an anomalous position. A ship is built in the United Kingdom, has passed Lloyd's and Board of Trade inspection, and carries certificates to this effect, notwithstanding which on entering Canadian trade she is forced to undergo Canadian inspection at a needless loss of time and considerable expense. A reciprocal arrangement must be arrived at whereby British, Overseas Dominion, and Canadian certificates as regards seaworthiness and efficiency shall be mutually accepted in all British Dominions. To continue as we are doing in this connection is idiotic in the extreme, and calls for prompt remedy by those responsible.

Canadian Mercantile Marine

The merchant marine, the building and operation of which is or should be a great national industry, is quite as deserving as any other Canadian industry of the friendly interest of the Canadian people and the intelligent consideration of our Government. The successful operation of an adequate Canadian merchant fleet is as vitally important to the prairie farmer as to the Ontario and Maritime Province manufacturers. Every mercantile nation in the world, carrying on an export business of any moment, demands a suitable fleet of its own nationality. Great Britain's merchant fleet of necessity antedated its overseas trade. Germany, when it first began to look abroad for markets, refused to depend upon British ships, but sought at once the creation of a German merchant fleet. France, laboriously wrought its own merchant marine, and Japan, the latest of commercial powers, secured its ships first and its trade afterwards. Not one commercial nation—save the United

States—has ever been willing to trust its foreign trade transport service to competitors—the instinct of self-preservation forbids such a policy.

We in Canada have a great coast line with ice-free harbors on both our Atlantic and Pacific shores, and numerous sites suitable for the establishment of shipyards. We can to-day supply almost all the raw material required, and granted sufficient encouragement, can produce all of it within a year. Taken in conjunction with the present abnormal demand for ocean tonnage, and the almost certainty that this will continue for several years at least, all these things constitute an opportunity for Canada which it would be folly to now neglect. To profit by these favorable circumstances it will be necessary to move quickly. If the Canadian Government will at once announce a comprehensive, broad and effective policy, granting sufficient encouragement to shipbuilding, we believe that the whole country, from the Atlantic to the Pacific, including all the territory that lies between, would approve their action. Never before was the necessity so great or the opportunities for meeting it so exceptional. Let us have action.

NEW POWER SUPPLY FOR HYDRO

AS a result of the recent conference held between members of the Federal and Provincial Governments, at Toronto, Ont., Sir Adam Beck, and representatives of the private power companies at the Falls, the Hydro-Electric Commission will in the near future, it is understood, have an additional 32,000 horse-power available to supply the demands of Ontario municipalities.

Although no contracts have been signed yet, and no price agreed upon, it is believed that the extra supply of power will be secured at a lower price than the commission has been paying for the emergency supply from the Electrical Development Co. The power will be supplied by the Canadian Niagara Power Co., which has hitherto been exporting the bulk of its power.

Until the new supply is available, the Hydro-Electric Commission will be unable to furnish any extra power to corporations under contract. At the present time every bit of the hundred thousand horse-power the commission has a right to demand from the Ontario Power Co. under its contract is being used. In fact, the peak load would be some 7,000 horse-power above that mark, but for the arrangement by which municipalities cut down their consumption at certain hours. It is stated that the commission could immediately dispose of at least 5,000 horse-power at once if it were available. The additional 32,000 h.p. will be obtained from the Canadian Niagara Co.

LITTLE KNOWN FACTS ABOUT GRINDING-CENTRES

By Howard W. Dunbar.

NO work can be ground more accurate than the centres in same, nor any nearer round or more perfect than the centre points that the work revolves on. It seems to be common practice, especially by grinding machine users, to make light of the necessity for accurate and well-made centres.

In observing methods employed in various factories, both large and small, this fact has been noticeable. Work has been observed in grinding machines in which the centre hole had no relief drill at the bottom of it, and instead of the angle of the centre fitting on the angle of the centre point, the work was revolving on the rounded nose of the centre in the machine, and wobbling about in the centre hole.

Other work has been observed in which the centres have been neither round nor of same angle as the centre in the work, and the surface of the centre hole has been rough, and full of lines and chatters made by the point of the drill used, instead of smooth and perfect as it should be when proper tools and proper machine operations are used.

We have seen grinding machine users lubricate the centre points and centre holes with red lead. This in itself is all right for lubricating heavy work, but when the red lead is mixed with equal parts of core sand and steel chips (as was the fact in the case in mind) accurate work is impossible. A little chip or foreign matter in the centre hole or on the centre is very apt to defeat very good intentions for nice work; therefore, it is necessary to keep the centre holes not only perfect and true, but also clean and free from foreign substances which would cause inaccurate work.

Centre holes should be made in size nearer in proportion to the size of the work being ground. Tradition, operators, foremen, and even superintendents will say that this is not correct, and that large centre holes will look bad, or are not necessary. Nevertheless, the truth remains; good work can only be ground on large, well-made centres and centre holes.

The centre points in the machine should be ground accurately, using the centre grinding attachment whenever the slightest imperfection in them occurs, and should always be ground when an exceptionally nice piece of work is to be finished in the machine. None of us would ever trust the weight and strain which we impose upon these small centre points by the use of too small centre holes in the work in any machine or in any operation, where we were expecting to carry a heavy load or do a lot of production. However, work has been observed in a grinding machine weighing several thousand pounds, resting upon too small centre points, in which less than 7-16 in. of the surface of the centre point carried this load.

Of course, it is useless to expect work to be ground accurately when the centre is not strong enough nor large enough to support the weight with a good, generous factor of safety. A good rule to follow is to keep the centres properly ground and hardened, at the proper angle, and smooth in finish, and to use just as large and just as well-made centre holes in the work as is possible, when refinement and accuracy are desired.—Grits and Grinds.

WAR TAX COLLECTION

NOTICES are being sent out by the Finance Department to companies and firms in every part of Canada requiring them to make returns under the provisions of the business tax imposed at the last session of Parliament.

Some 15,000 such notices are being issued, which means that approximately this number of companies and firms will be required to contribute a large slice of their excess profits made since the war. For the purposes of the tax the country has been divided into eleven districts—two in Quebec, four in Ontario, probably one in Nova Scotia and Prince Edward Island, one in New Brunswick, one in Manitoba, one in Saskatchewan and Alberta, and one in British Columbia.

The tax is 25 per cent. of all profits made since the war in excess of seven per cent., in the case of incorporated companies, and 10 per cent. in the case of firms, individuals and partnerships.

DYESTUFFS INDUSTRY

ACCORDING to the Iron Trade Review, Cleveland, Ohio, Dr. Norton, the author of a report on the present dyestuff situation issued by the Bureau of Foreign and Domestic Commerce, has expressed the opinion that the United States is to have a permanent dyestuff industry. The textile and allied industries, he says, are united in the determination that the country shall not again be exposed to such a famine as it has recently experienced. The large organizations of dyestuff users have expressed a willingness to bear the burden of higher prices than prevailed before the war, if necessary. Most of the companies engaged in manufacturing coal tar compounds are planning to continue their production along the lines already taken up and to enlarge such production, or enter upon the manufacture of additional intermediate or primary dyes, as circumstances warrant.

AN ANCIENT SOLUTION OF A MODERN PROBLEM

By A. L. Haas.

IN the desire for easy machining and in the modern tendency to reduce complexity even by neglect of economy in material, factors of considerable importance may be overlooked.

Take for example a high speed vertical engine running at 800 to 1,000 revs. per minute, it is obvious that all material in the moving parts must be of the finest quality. To this end the material for piston and connecting rods and crankshaft is duly tested, yet the curious fact remains that failure of connecting rod bolts is the most common cause of a wreck. The material for these bolts is rarely specified, they are frequently made from bar material and as they are only bolts they get less consideration than they deserve. Often they are made of high carbon steel to reduce weight. The rod material on the other hand whatever its tensile strength has to fulfil exacting requirements with regard to extension and reduction of area under test.

Where the Danger Lurks

Granted suitable material, a more pertinent question which is never specified arises in the machine shop. Few turners are aware that sharp square corners at a shoulder cannot be produced except by undercutting the material at this point and so reducing its diameter. In a desire for perfect finish under the head this reduction of cross sectional area is almost invariably found in the bolts mentioned.

There is no need to labor this point to anyone experienced in breaking tensile specimens or to point out the danger of even minute nicking at a change in section. This combination in the case of steel will take tons per square inch away in the tensile result, while if combined with shock stress disaster is cordially invited in practice.

Another point concerns screw-cutting in the lathe. As such bolts are finished all over, and are considered good work it is usual practice to finish them in an engine lathe.

In screwcutting the breakage of all tool points is caused in the withdrawal of the tool at the end of the cuts. A cut thread in the lathe is considered superior to one cut by dies. The sharp nick left at the end of thread has exactly the same effect as an undercut shoulder under the head, it invites breakage. In the case of die cut threads such nicking is less evident since the thread has an effective taper at the end. Working a bar of uniform section must, however, punish the dies and lessen their life.

A Feasible Contention

It is a little curious that a desire for the best possible article made in the most expensive manner should lessen its strength; but such is the contention now advanced, it is thought with due reasons, in the case of uniform diameter bolts. It explains also why black commercial bolts do not fail so unaccountably as a carefully made lathe job.

The remedy for both defects is the same:—The provision of a distinct radius under the head of the bolt and a radius clearance for the thread tool. Using a turret lathe the clearance for thread can be made by the cross slide parting tool suitably shaped. A circular groove round in shape is the desired clearance for the thread tool. Such a groove the depth of thread only may at first sight look odd but does not weaken the bolt. Where the thread tool usually finishes is a point that the chaser cannot be expected to finish properly.

The connecting rod bolt illustrated obviates both defects, it has a radius under the head, the brasses being finished in a similar manner, the stem is reduced in diameter to allow the threading tool to pass into clearance when screw-cutting.

Design Established by Age

The design is as old as the proverbial hills, but the modern machine shop is apt to consider its product from its own point of view without regard to other questions. Granted access to a testing machine the matter can easily be put to the proof. The dangers are more obvious in the case of steel than of wrought iron. Taking an analogous case, that of small screw blanks headed cold, if no radius under the head is provided either by design or wear, the enfoliation produced makes heads which almost drop at a touch. If, however, such radius is present, the head may be battered with a hammer and turned over square to its normal position without fracture.

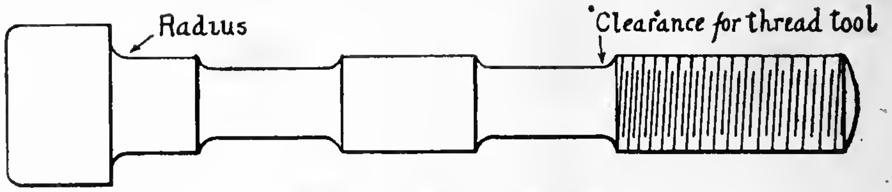
Because a piece is machined and not deformed, the point at issue is overlooked while small size bolts to-day fulfil relatively high missions in the case of automobile and aeroplane engines. The temptation open to make these in automatics without reference to the points raised may lead to fatality.

A recent failure from this cause wrecked a high speed engine driving a 700 k.w. generator and shut down half the product of a factory engaged upon important work. The damage a broken bottom end bolt can cause must be seen before the effect of momentum and high speed can be realized.

Trifles Cause Damage

Such considerable results, however, can accrue from neglect in the machine shop and show that the veriest trifles can overset hundreds of pounds worth of careful work. Such minutiae are, however, basic facts for the engineer to consider and they place a large responsibility upon the mechanic.

The matter is of supreme importance wherever steel is employed in the connection indicated and if considerable stress is here laid upon what is a simple matter, it is because in spite of the facts being well known they are repeatedly neglected.



CORRECT DESIGN OF ROD END BOLT.

More than one large steamer has limped to port on less than half speed with a cylinder cover gone up through the skylight owing to the cause cited. Numerous failures of high speed generating sets can also be attributed to the same reason. Examination of the spare bolts usually supplied and the type of fracture destitute of any reduction of area or apparent elongation in the material will testify to the facts of the case.

Frequently the material of bolt is described as rotten because of the sudden short character of the break showing no apparent flaw. The entire responsibility is, however, upon the machine shop for the radius under the head, while the draughtsman may take his share in the design of the bolt where the break occurs at the end of the thread. A large factor of safety seems of no value, and many engines now working are a public but unrealized danger owing to the bottom end bolts.

GETTING THE MOST FROM HIGH SPEED DRILLS

by J. R. Hamilton

IN addition to such essential features as the proper method of grinding the cutting edges of twist drills, the speed and feed at which they should be operated, it will be found that better results will most often be obtained after the drill has become warmed up. While it is never advisable to run a drill too hot, it must be remembered that twist drills, especially those made from high speed steel, can be operated to better advantage after they have attained considerable heat, at which point they become much tougher and consequently stand up to a heavier feed. When cold, high speed steel is often quite brittle and easily broken; for this reason, care should be exercised in cooling the cutting point of twist drils after they have become over-heated, as there is a possibility of creating minute cracks when dipping the drill in cold water.

This fault often results from careless grinding by an inexperienced operator. In an effort to get the drill ground quickly, excessive pressure is used, and the point quickly becomes over-heated, often to the extent where the color is drawn. The workman, not realizing the harm done, will immediately dip the point into a bath of cold water, when the sudden chilling of the keen edges will cause small cracks, so small as to be imperceptible with the naked eye, but which may result in the edges chipping when the drill enters the metal. Unless great care is taken, the forcing process of grinding will generally result in a cutting edge too soft or too brittle. It is sometimes profitable to preheat a twist drill before starting on a job. Do not let the drill become too hot, and, when cooling, use tepid water to avoid sudden chilling of the thin cutting edges.

GETTING A JOB DONE QUICKLY

by R. James

MACHINE shop practice often requires that certain work be performed in as short a period of time as possible, in order to avoid unnecessary delay in the operation of another machine or section of a workshop. To successfully accomplish this, it is necessary that the workman should be entirely familiar with the machine he is operating, and also have an exact knowledge of the work he is doing. Sometime ago, while passing through a small repair shop, I noticed a young fellow working on a shaper with the cutting tool travelling about 2 inches over each end of the work. As the length of the piece was about 4 inches long, it appeared to me that he was using an extra long stroke to complete the cut. After watching him for a few moments, I stepped up and asked him what his object was in having such a long stroke on that length of cut. Justifying himself, as it were, the chap replied "Well you see, the boss wants this job in a hurry, so I am cutting a little fast."

Thinking to enlighten him I asked, if it would not be better to shorten the stroke and throw the belt up on a higher speed; but he seemed surprised and said, "The tool would not stand the higher speed." He did not seem to realize that by shortening the stroke and using the next speed, that the tool would be operating at practically the same rate, yet accomplishing the job in much less time. To convince me—as he thought, he finally reduced the stroke and threw up the belt, expecting, I believe to see the tool begin to smoke. However, he was agreeably surprised to see things running smoothly and the metal coming off nearly twice as fast. The next time he has a job to do in a hurry, he will likely use his head as well as his eye.

SPECIAL VISE JAW SAVES MAKING DRILL JIG

By F. H. Mayoh

IT is the custom when drilling a number of duplicate parts to make up a jig for guiding the drill so the pieces will be drilled alike. These jigs are apt to be

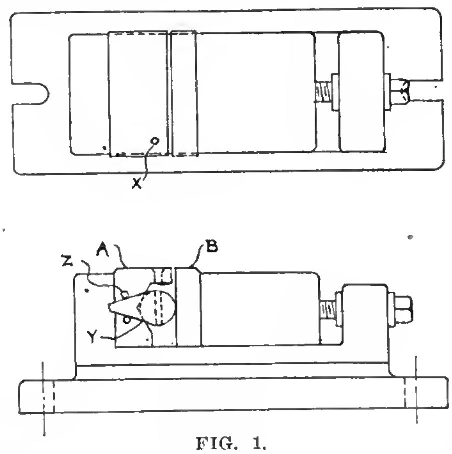


FIG. 1.

more or less expensive depending upon whether or not the part drilled is complicated or easily adapted to being gripped.

By the accompanying sketch Fig. 1 is shown a method which sometimes can

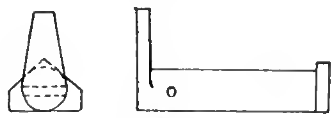

FIG. 2.

be used to eliminate or save the expense of making a jig. This illustration shows the plain vise such as is used on the milling machine fitted with a special vise jaw A, this jaw has a hole at X for guiding the drill while the vee Y centralizes the work which is gripped by the jaw B, which is a standard jaw.

The work is illustrated in the sketch Fig. 2, and the method of gripping is obvious as the round portion is gripped in the manner described and the drill is fed through the hole X into the work and each piece will be in duplicate. This jaw has two pins Z for locating work radially from the shaped end.

VALUE OF BELT TIGHTENERS

Professor William W. Bird, of Worcester Polytechnic Institute, with Francis W. Roys, have been experimentally investigating the effects of atmospheric humidity upon oak tanned leather belting, with the following definite conclusions:

1.—If a belt be set up at a low relative humidity, slipping will occur with a marked rise in the humidity, especially if it is accompanied with a rise in temperature.

2.—If a belt be set up at a high relative humidity, excessive stretching and excessive pressure on the bearings will result from a decided decrease in the relative humidity, especially if accompanied by a fall in temperature.

3.—If a belt be set up at a medium relative humidity the tensions will not be excessive at low relative humidities nor will there be any great danger of slipping at high relative humidities unless accompanied by excessive temperature changes.

4.—If a belt be set up at any relative humidity with a spring or gravity tightener, a load 50 per cent. greater than the standard can be transmitted at either high or low humidity without any of the troubles.

PROPER WIRING AND MOTOR PERFORMANCE

THE superintendent of a sash and door factory, where electric motors are used for driving the machines says he finds something new all the time. He finds that proper wiring has much to do with the satisfactory performance of motors. For instance, an 8 horse-power motor did not do the work required, and he was about to exchange it for a 12 horse-power motor. After the new motor arrived he was told that the wire would have to be changed, as the one in use was too small for the necessary current. The wire was duly changed, but for lack of a coupling, the old motor was connected, to be used until the coupling arrived. To the surprise of the superintendent the old motor did the work as well as could be wished.

TRANSMISSION SAFETY—I.

AN important factor in securing freedom from accidents in machine shops and factories generally is the proper safeguarding of the apparatus used for power transmission. In a large shop that does not have individual electric motors for its various machines, a great many belts are used; rope and chain drives are also employed occasionally. Numerous accidents occur in connection with equipment of this kind, which may be divided into two principal groups—the first comprising those due to the breaking of the belts, ropes, and chains, and the second, which is more important, including those in which the hands or clothing of workmen are caught in the moving transmission apparatus.

Belt Depreciation

Wear and deterioration of belts may be caused in various ways. Frictional heat injures leather belts by burning the fibers, and this action is particularly rapid when the belts slip excessively. Belts hanging loose on revolving shafts, and even in operation, may be rapidly worn away by abrasion when the air of the shop contains gritty dust. Temperature, moisture, the tightness or looseness of the belts, and the general condition of the lacings and fastenings, all have an influence upon the life of the belts, and also upon their efficiency in transmitting power. Driving chains wear chiefly by the friction between the links and the sprockets.

In case of deterioration from any of these causes, it is only a question of time when breakage must occur, and then the results are likely to be serious. When a belt breaks the adhesion between it and the driving pulley sometimes holds the belt long enough for it to roll up, after which it is shot off at a speed comparable with the speed of the pulleys over which it runs. At short range a roll of this kind may be as deadly as a cannon ball, and it takes no very active imagination to picture the result, when it is discharged into the midst of a busy shop. A broken belt may also start to roll up, get caught, and then pull down a section of the line shafting. The only method of preventing these accidents is to provide suitable guards for the belts so that even if they break they will not be thrown off. Frequent inspection to remove dirt and grit, and to find weak places, is also of great value. If the belts are seriously worn, the expense of replacing them should not be spared, because the added efficiency and greater freedom from accidents will be ample compensation.

Unprotected Belts

The second general kind of accident caused by transmission apparatus is that in which a workman is caught in a moving belt by his clothes or hands and thrown to the floor or whirled about the shafting. This is one of the most fearful of all industrial accidents, resulting in serious mutilation in almost every case, and we could easily fill pages with the awful details of accidents of this kind. The only way to eliminate such hazards is by carefully guarding all power-transmission equipment where there is the slightest probability of a workman getting caught.

A general point that should be considered in the installation of belt guards is the arrangement of the power-transmission apparatus. This is most important, of course, when a complete installation of new machinery is about to be made; for in cases of this kind it is far easier to safeguard the belting properly, if the shop is laid out with due attention to the needs for the guards. When no preliminary thought is given to the subject of safeguarding, the chances are that no guards will be installed, or else the work will have to be done subsequently at a much greater cost, and will cause more or less temporary or even permanent inconvenience. Moreover, human nature is constituted so that when it is inconvenient to do a certain piece of work, a reason can usually be found for delaying or entirely neglecting it; and when it is the guarding of transmission apparatus that is under consideration, this reason will often be considered to hold good until an accident occurs.

Belt Guard Types

A preliminary study of the problem, at the time the shop is laid out, makes it possible to have the guards installed so that they will not obstruct the aisles or passageways, nor interfere with the working, repair, or inspection of the machines. It may also be decided, in this general plan, whether open methods of guarding by means of rails of pipe or angle iron are to be used in certain locations, or whether it is better to entirely inclose the apparatus. All vertical and inclined belts (and rope drives also) should be completely inclosed to a height of at least 6 feet above the floor, if the guards must be less than 15 inches from the belts. Guards of pipe or angle iron may be used, if they are at least 24 inches high and are placed 15 inches or more from the belt, rope, or pulley that is to be guarded.

Let us assume that a pipe-rail guard is placed about a belt transmitting power from the main shafting on the floor below to a machine on the floor above. If the guard is close to the belt a workman leaning against the guard on the floor above may have some part of his clothing drawn into the narrow slit in the floor by air suction, or by the belt-lacing or clips, and unless the cloth gives way a serious accident may result.

Belt Hazard Important

It is of course logical that the speed and the width of the belts should be taken into account in estimating their hazards. All overhead belts, six inches or more wide, that run at a speed of 1,800 feet or more per minute should be very substantially guarded. The wire-mesh guard framed with angle iron, or the ladder guard turned over at each end so as to include the pulleys, is recommended. In the case of the ladder guard the rungs (if rungs are used) should be close enough together to prevent the belt from falling to the floor in case a break occurs. It is very much better, however, to use lattice work instead of rungs, between the sidebars of the guard. If the upper part of a horizontal belt or rope drive is less than 6 feet above the floor, the belt or rope should be completely inclosed on the sides and top or guarded by a standard railing located at least 15 inches from the belt. Unless the lower part of an overhead belt is 7 feet or more above the floor, the belt should be guarded both on the sides and bottom.—Travelers Standard.

CORED CASTINGS FOR CAPSTAN LATHE WORK

IN all cases where castings have to be turned up, it is essential that the metal shall cut freely according to its class, hard or soft castings having to be made to suit varying duties, but without exception more care has to be given to work dealt with in capstan lathes, as in these the tools have to be changed as seldom as possible. Sand or siliceous matters embedded in the metal give the most trouble, and to prevent annoyances in this direction, the moulds should be faced with plumbago worked up to a fine surface with a soft brush, and cores should be coated with a wash composed of about 80 per cent. finely ground plumbago and 20 per cent. china-clay, if procurable, or some other clay free from sand in other cases. Necessarily, the cores will be in a dried condition when the wash is applied, and will be again dried before placing in the moulds. Plumbago, when properly put on, prevents the adherence of sand, and produces a softer skin to the casting. The use of it adds to the foundry expenses, but against this there is a large decrease in machining costs which more than compensates for the increase in foundry costs.

Brampton, Ont.—The local authorities have requested the Hydro-Electric Commission to purchase three 150 kw. and three 300 kw. transformers.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division will be found a useful companion study.

Question.—What is the method used when squaring a mixed number, such as 9¾?

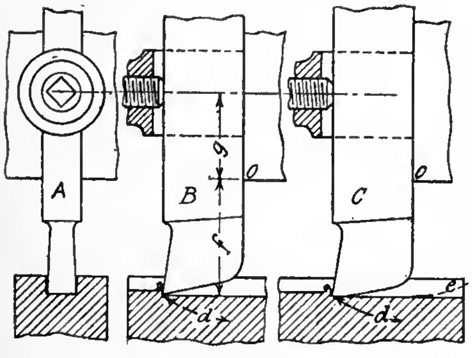
Answer.—The squaring of mixed numbers may be accomplished in several ways. The method generally adopted is to multiply the number by itself, as is done in the case of whole numbers; by the fractional method you first convert the number to an improper fraction. To do this, multiply the whole number of the fraction by the denominator and add on the numerator; the number thus obtained will be the numerator of the desired fraction, and of the same value as the mixed number, thus: $(9\times4)+3=39$, and 39 over 4 will give $\frac{39}{4}$, and $\frac{39}{4}\times\frac{39}{4}$ $=95\ 1/16$. The best method, however, is to convert the mixed number to a decimal, and proceed as in whole numbers, thus: 9¾ equals 9.75, and this multiplied by itself gives 95.0625. Another method may be applied, that of using the formula $(a+b)^2$, which is resolved into $a^2+2ab+b^2$, where (a)= the whole number, and (b)=the fraction, thus $9\times9=81$, $2\times9\times\frac{3}{4}=13\frac{1}{2}$, $\frac{3}{4}\times\frac{3}{4}=9/16$, total 95 1/16.

No set rule can be recommended for the squaring of mixed numbers, as the latter may require to be solved by different methods. The nature of the question, however, will generally indicate the best way of arriving at a solution.

* * *

Question.—What is the best means of preventing chattering when shaping a piece of work with a square-nosed tool?

Answer.—The chattering of the tool when working on a piece of metal may start from many causes, such as the tool being improperly held, too much overhang, slackness in the moveable parts of



the machine, or the tool not ground to suit the work being machined. Under certain conditions it may be very difficult to entirely eliminate the tendency to chatter, but in the majority of cases it is possible to overcome the source of trouble and produce a clean, smooth job. As may be seen in the sketch, the action of the cutting operation tends to move the point of the tool through the arc (d). Now, if this point is such a distance from the fulcrum (O) as to cause excessive leverage—as shown by the proportion of the two lever arms (f) and (g), the possibility of the tool digging in is increased. It is, therefore, always advisable to have the cutting tool extend as short a distance as conditions will permit. In addition to this, the gibs of the various slides should be adjusted so as to remove any lateral motion, but leave the ram free to move in the direction of the cut. However, even after all these apparent causes have been removed the chatter may continue; and, as is often found, the trouble will be traced to the cutting tool itself. As previously mentioned, the point of the tool tends to travel through the arc (d); then if the clearance of the tool is too great, as shown at (B), the tendency to "dig in" is more pronounced. It is good practice to have very little clearance on shaper tools, especially directly back of the cutting edge, as shown at (C). To reduce the possibility of "digging in" to the minimum, the cutting edge of the tool should come directly below the point (O), when the action of the cut will tend to move the tool from the work, as shown at (e).

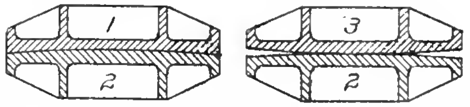
* * *

Question.—When boring out long cylinders, I have sometimes experienced difficulty in overcoming a small ridge which has formed at some point between the two ends. What would cause this, and could you suggest any way to remove the trouble?

Answer.—To find a satisfactory solution to a problem of this description, it would almost be necessary to be on the ground, as there may be many points come up which could not be included in one solution, i.e., the condition of the tools, the method of holding, the length of the cut, the accuracy of the movable parts of the machine, the nature of the work itself, etc.; any one of which, or a combination of several, may prove to be the source of the trouble. It will often be found, where a machine has been working continually on work of a certain length, that the ways of the lathe have become worn, and when a job of an extra length is being handled, there is a tendency of the saddle to rock when it reaches a certain position in its travel. One of the most common causes of trouble of this nature is the stopping of the machine while the cut is in progress. It may often happen that the position of the tool is at some point between the two ends when the shop whistle blows. The workman will naturally shut off his machine for the noon hour, or possibly over-night, and when he returns in the morning he will shove over the lever without a thought as to what may have happened in the meantime. To all appearances everything is as it was the night before; but when the cut has been completed, the calipers or gauges will find a ridge where the tool has started after a period of rest. The cause of this is that the metal will become heated to a certain extent while the tool is cutting, thus expanding the work, and if the machine is stopped and left to stand for a time, especially for a long period, the work will cool off and contract, which allows the tool to dig in to the metal (very little, it is true, but often sufficient to cause trouble, particularly if the work requires to be very accurate). It is always advisable to have the cut go the entire length of the bore without a stop.

* * *

Question.—Why is it necessary to work with three face plates of similar dimensions in order to obtain an accurate surface?



Answer.—While it may not be absolutely necessary to use the three plates to produce a true surface, the best results are obtained by following this method. It is possible to secure a fairly accurate surface by means of a good reliable straight edge, but the plan usually adopted is that of the three plates. To show that error may arise if only two plates are used, we will suppose that the two plates have been planed and scraped to what may appear a perfect contact at every point, and from all visible indications this may be true; but instead of a flat surface, it may be one conforming to the convex and concave surface of a large sphere, as shown in the exaggerated sketch at the left. Now by the use of an additional, or third plate, it is possible to eliminate even the smallest error in this direction. Suppose, for instance, that the two plates (1) and (2) were to show a perfect bear-

ing, and that the plate (3) in contact with the plate (1) should show a similar bearing, it would not prove that all three, or, in fact, any one surface was perfectly flat. By placing plate (3) in contact with plate (2), however, any error—no matter how small—will be immediately indicated. By the use of three surfaces, therefore, the chance of error is almost, if not entirely, removed.

* * *

Question.—What is the capacity, in cubic inches, of the British Imperial gallon; also that of the U. S. gallon?

Answer.—The standard unit measure of capacity for the British Imperial gallon, for either liquid or dry material, is that of ten Imperial standard pounds of distilled water having a temperature of 62 degrees, weighed in air of the same temperature, and with the barometer at 30 inches; the water to be weighed with brass weights. While the weight of a cubic foot of water is usually considered to be approximately $62\frac{1}{2}$ pounds, several authorities give the weight as being 62.355 pounds. From this the Imperial gallon will contain $\frac{1728 \times 10}{62.355} = 277.123$ cubic inches. However, the value generally used is that of 277.274, which for all ordinary purposes is sufficiently accurate.

The U. S. gallon weighs 8.345 pounds, and a cubic foot of water at 39.2 degrees F. is 62.425 pounds. The contents of the gallon will, therefore, be $\frac{1728 \times 8.345}{62.425} = 231$ cubic inches.

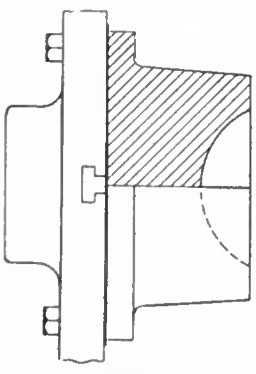
Question—When clamping work to the face plate by means of bolts or cap screws, we have often had trouble with the work slipping from its original location; what is a good method to keep the work in a fixed position?

Answer.—Where circumstances will permit, it is sometimes advisable to turn a shallow boss on the base of the casting when facing it off, which will fit into



a corresponding recess in the face-plate of the lathe. In addition to preventing any slip, it offers increased facilities for resetting if the occasion should arise. However, the use of a boss and recess cannot always be resorted to, in which cases the application of a piece of ordinary wrapping paper will often accomplish the desired result. By placing the paper between the face-plate and the work, as shown in the sketch, the adhesive properties are greatly increased, and by giving particular attention to the clamping arrangement, the work will remain quite secure under normal conditions.

* * *

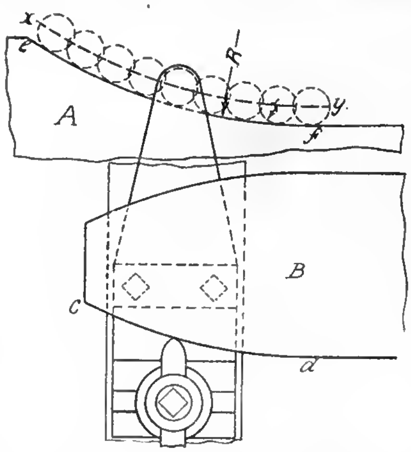
Question.—What should the ballast of an accumulator weigh to maintain a pressure of 350 tons on a 24-inch piston, and what would the pressure be per square inch?

Answer.—To exert a pressure of 350 tons at the press, it is obvious that the source of power—or the weight of the accumulator—must equal that at the press. To calculate the pressure per square inch, the total pressure must be divided by the area of the piston, thus:

$$\frac{350 \times 2000}{24 \times 24 \times .7854} = 1538 \text{ pounds per square inch.}$$

* * *

Question.—In constructing a cam for turning the profile of a shell on an engine lathe, is the shape of the cam the same as that of the nose profile?



Answer.—If the travel of the tool is governed by means of a fixed point in contact with a cam, the shape of the generating surface of the cam will be approximately the same as the shell profile. The general practice, however, is to have a roller acting on a cam, which necessitates the forming of a cam that will cause the true generating point or that of the centre of the roller to travel in a path corresponding to the nose contour. For instance, the profile of the nose on a 6-inch shell is an arc of a circle, having a radius of 11.92 inches; therefore, if the diameter of the cam roller is 1 inch, the shape of the cam surface will require to be an arc of a circle, having a radius equal to that of the shell profile plus the radius of the cam roller. This can be more clearly shown by referring to the sketch, and as the position of the point of the cutting tool is controlled by the position of the cam roller, it is obvious that the cam proper must have a shape generated from the position of the cam roller in the various points along its path of travel.

MOTOR BOATS FOR CHINA

A RECENT number of Shipping and Engineering contains an excellent article upon the growing demand for motor boats to ply upon the inland waters of China. The writer of the article states in part as follows:—The export of marine motors from Great Britain to China has, owing to the war, for the present come to an end, and the trade is now entirely in the hands of American manufacturers. These engines are turned out in 1, 2, 3, 4 and 6-cylinder models, ranging in power from 5 B.h.p. to 110 B.h.p. The motors that have undoubtedly taken the greatest hold on the markets of China, are those which are sold in stationary sets of 3 to 11 h.p., and marine sets from 3 to 50 h.p. A still smaller size is the $2\frac{1}{2}$ h.p. detachable motor which, working with magneto, has found great favor for use with light skiffs and ship's boats.

The larger sets have now been adapted to operate on kerosene, an improvement that adds a great deal to their utility in outports where petrol is difficult to obtain. The paraffin engine is the one that will be most used in China, because of the ease of obtaining fuel in almost any little village at which the boat may happen to stop. Again the simplicity of design of this type makes it a motor that can be operated with safety by the untrained Chinese.

Simplicity of construction and manipulation is one of the principal requirements of a motor intended for the Chinese market. It must be borne in mind by the manufacturer, that his engine is likely to run with the minimum of operative intelligence for long periods without an overhaul, and it might possibly require, in motors intended exclusively for the Chinese market, some small sacrifice of efficiency or lightness, in order to produce an engine that will be proof against the misuse it would probably receive.

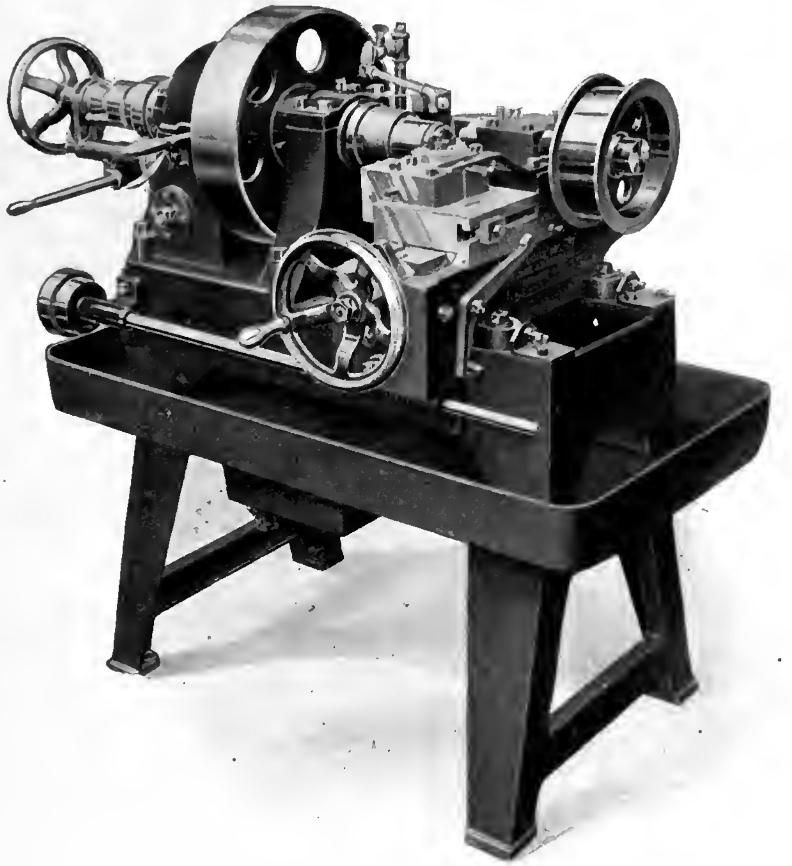
A flux is a substance which, added to ores, metals, or other bodies, combines with the impurities and forms a fusible slag. A flux is added to slag off impurities, to protect the surface of the metal, and to produce a fusible mass. Oxides may be removed from metallic surfaces by using a suitable flux; sometimes an oxidizing flux is used, in order to oxidize impurities, which then combine with the flux to form a slag.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

MILLER FOR STEEL NOSE SOCKETS.

STEEL nose sockets for 18 pdr. shrapnel are now largely used instead of brass sockets. A miller for machining these steel sockets has been developed and put on the market by Edwin J. Banfield, of Toronto. The machine is built in two styles; one for the outside operations and the other for milling the inside thread only. The former will be dealt with first as the outside operations are completed before the inside thread is milled. The accompanying illustration shows the general design of the machine which is of rigid and substantial construction, and weighs 1,200 pounds. A 3 in. shaft is driven by a 16 x 4 in. pulley direct from the line shaft while the milling fixture has an independent drive also direct from the line shaft. A worm gear driven by a pulley at the back revolves the shaft when the thread is being milled; the pump for supplying the cutting compound is also driven from this pulley.



MILLER FOR STEEL NOSE SOCKETS.

The steel sockets when received at the machines have been bored, counterbored, faced inside and outside, and the hole for the powder tube drilled. In the following operations the face of the socket is finished, the undercut and shoulder at the back of the thread are formed, and the outside thread milled. The socket is held on an expanding mandrel which is tightened by means of a taper plug actuated by a hand lever and clutch mechanism. The first operation consists of rough turning the outside diameter, a tool on the cross slide under the work being used for this purpose. The next operation is performed by a series of tools carried in the front tool holder. The first tool faces up the powder tube bars. The second tool finishes face of socket and the radius on the powder tube boss. The third or form tool finishes the shoulder, undercuts for the thread, forms the O.G. on face of socket and turns the diameter to finished size ready for milling the thread.

The final operation consists of milling the thread which is performed by a milling cutter carried in a sliding bearing mounted on the cross slide at the back. The fixture has an independent drive and the feed of the cutter is controlled by a chaser engaging with right hand threads on the outside of the chuck. The socket turns one revolution while the thread is being cut, the shaft being revolved by a worm gear controlled by a clutch. The machine is equipped with a two-speed feed for the carriage, also a rotary pump ensuring a steady flow of cutting compound to the tools, the pump being fitted with a relief valve permitting the compound to be turned off at will. The machine has a capacity of approximately 30 sockets per hour.

The machine for milling the inside threads is practically identical with the one described above with the exception that a collett chuck is used instead of the expanding mandrel and the front tool holder is dispensed with. The socket has now an outside thread which is used for holding it in the chuck while the inside threads are being milled. The socket is first screwed into the threaded collect chuck, the draw-back mechanism being operated by a lever as in the case of the other machine. The miller is driven from a reversing countershaft so that the sockets can be put in the chuck or taken out without stopping the machine. The milling spindle is carried in a sliding bearing mounted on the cross slide. Ample travel is allowed for the cutter so that the operator can handle the work with the freedom and to protect his hand, the cutter is covered by a hinged cap which is thrown back when in operation. The feed of the cutter is controlled by the chaser engaging with right a hand thread on the outside of the chuck. The machine is fitted with a rotary reversing pump equipped with relief valves to ensure a steady flow of compound irrespective of the direction of running. This machine has a capacity of approximately 90 sockets per hour.

MICHELL JOURNAL BEARING

THE Michell principle of thrust absorption has proved so successful as applied to thrust-blocks that there has naturally been a strong inducement to extend its application to ordinary journal bearings. The bearing which is illustrated in Figs. 1 and 4 shows a development of the latter. The bearing represented has been applied to two circulating pumps at the Newport Power Station, Melbourne, Australia. The pumps were made by the G. Weymouth Proprietary, of Melbourne, and are of 220 horse-power, the shaft speed being 490 revolutions per minute.

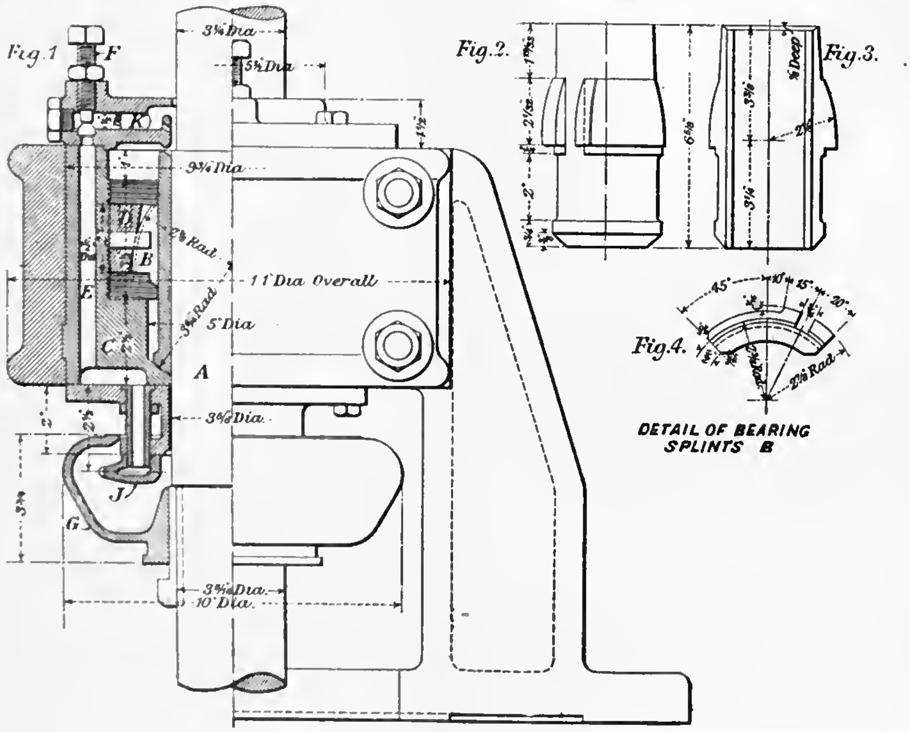
As will be seen from Fig. 1, the shafts are vertical, and, as is well known, sat-

isfactory lubrication is in such case a matter of some difficulty owing to the tendency of the oil to run out at the bottom. In the bearings illustrated, however, this difficulty is completely overcome. There is a definite oil circulation, which is maintained by the rotation of the shaft, and leakage of oil entirely prevented. The journals have, we are informed, been running satisfactorily for some months.

Referring to the illustrations, it will be seen that the shaft A is surrounded by four splints or brasses B, the design of which is shown in detail in Figs. 2 and 4. The ribs or projections shown on the back of these splints are turned to a spherical surface, but, as indicated in Fig. 4, this surface is cut away one-sixteenth clear on the side of the leading edge of the splint, so that when in position the brass can tilt a little to facilitate the entrance of oil between the lubricated surfaces. The lower ends of the splints are also turned to a special surface struck from the same centre as that to which the ribs are turned. The splints rest by these spherical surfaces on the housing C of the bearing. A hollow cone D is screwed down on to the ribs of the splints, holding them in position as indicated. By screwing this cone up or down, the oil clearances between the brass and journal surfaces can be adjusted. It will be seen that by this arrangement the bearing is set up towards the centre of the shaft from four directions, instead of from two, as with ordinary two-part brasses.

The lubricating oil draining from the bearing falls into the cup G, which is keyed to the revolving shaft. Dipping into this cup is a nozzle J, and the oil carried round by the rotation of the cup rushes up this nozzle and through the controlled by screwing up or down the passage E to the top of the bearing, whence it is distributed through the port K. The amount of oil pumped can be set-screw shown at F. A continuous circulation of oil between the rubbing surfaces is thus secured.

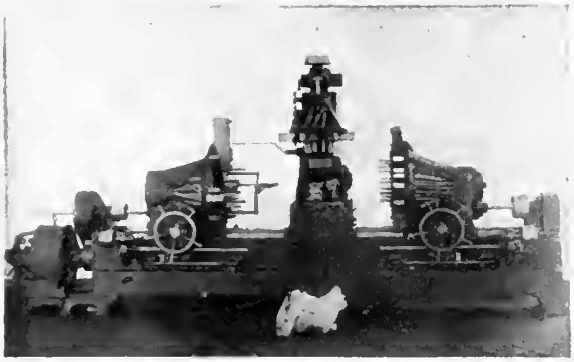
H. T. Newbigin, A.M.I.C.E., 3 St. Nicholas Building, Newcastle-on-Tyne, is the representative of the device in Great Britain



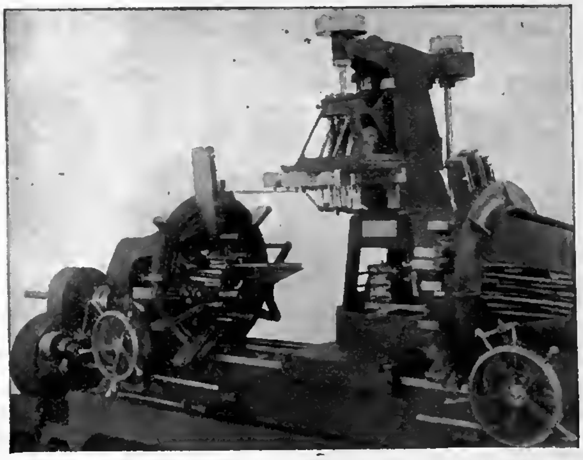
THE MICHEL JOURNAL BEARING.

MULTIPLE SPINDLE DRILLING MACHINE

FOR drilling all the holes in an automobile transmission at once at one setting, the Baush Machine Tool Co., of Springfield, Mass., have perfected the multiple spindle drilling machine shown in the accompanying illustration. This machine is unique in that there are 46 holes in each transmission case and the drilling is done regardless of the fact that some of the holes are on an angle and vary in size from 3/16 to 1-11/16 inch. Each drill runs at the same speed and each group of drills has independent feed.



MULTIPLE SPINDLE DRILLING MACHINE.



MULTIPLE SPINDLE DRILLING MACHINE.

The machine is operated by a 25 horse-power, 230-volt, 1,400 r.p.m., commutating pole, direct current, Westinghouse motor, through a main driving shaft placed at the rear of the machine, connected to the horiznotal heads by steel gears and cloth pinions, and connected to the vertical head by bevel gears. The motor operates equally well in either direction of rotation and can be reversed without changing the position of the brushes.

The bed of the machine is supported on feet, providing ample space for cleaning underneath and preventing the floor from becoming water-soaked if drilling compound is used. All reciprocating parts are enclosed in cast guards, effectually protecting operators from injury. Various spindle speeds are obtained through gear reductions encased in oil-tight boxes on the heads. The spindles are equipped with ball thrust bearings and Baush universal ball joints. An improved type of arm allows a centre distance between holes equal to the diameter of spindle. Spindle may be ad-

justed for different lengths of drills by operating but one screw at the outer end of arm.

The horizontal heads have standard belt-driven feed with automatic control and quick traverse by hand wheel. Vertical head and cluster box slides are automatically controlled by left hand through trip rod and bell crank which operate jaw clutch on reversing gears in gear box. These gears control shaft operating pinion and racks attached to vertical head and slide.

In operation the left hand head is brought forward, automatically engaging feed of vertical head and cluster box slide, which travel the required distance and automatically return to neutral position. The feed for right and left hand head is next engaged by levers. At the same time a spindle on the box jig drills the hole. The feed is automatically tripped by stops, and the heads return to neutral position, completing operation.

HUMPHREY GASOLINE PUMP

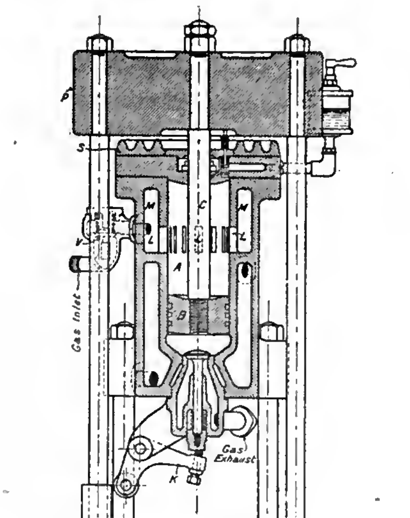
CONSIDERABLE interest was aroused some time ago when an English engineer by the name of Humphrey adapted the principle of the gasoline engine to a direct acting pump, in which the usual iron piston of the engine is replaced by a column of water, on which the pressure of the explosion is exerted. By a suitable arrangement of passages the operation of a four-stroke cycle was maintained, the construction of the apparatus rendering it particularly adapted for dealing with large quantities of water. the Chingford reservoirs of the Metropolitan Water Board, near London, being a conspicuous example of its successful application.

Certain features of the original pump prevented its use in small sizes, but the merits of the principle have induced the Humphrey Pump Co. to bring out a new type in which the gravity effect of the original water column is obtained by the use of a vertical reciprocating mass of metal.

The new type of pump is arranged to work on the two-stroke cycle, using ordinary gasoline, and is similar in appearance to a vertical simplex pump. A part sectional elevation is given showing clearly the explosion cylinder with its valve gear. The pump barrel or water end is bolted to the pump cover, which has projecting feet, on which the weight of the whole structure rests. Three vertical columns or struts extend upward from the pump cover and support the cylinder A, containing the piston B and piston rod C. The latter passes through a suitable packing gland, and carries on its upper end the massive cast iron block P, which is connected by means of two vertical side rods with cross-head Q, to which the pump rod D is fastened. The pump bucket E has a disc valve F on its upper face, and a similar valve G is placed in the bottom of the barrel.

Pump Single-Acting

It will be seen, therefore, that the pump end is single acting, the pumping of the water being done on the up-stroke only. As already mentioned, the cylinder A acts on the two-stroke cycle, and being arranged so that the force of the explosion is exerted upwards, an impulse



PART SECTIONAL ELEVATION OF GASOLINE PUMP

is accordingly given to the pump bucket on every upward stroke.

Surrounding cylinder A is a water jacket, and above this again is an annular space M connected with the cylinder space by ports L. Assuming that a charge has been fired with the parts in position as shown, the piston travels upward, passing the ports L and enclosing a small volume of mixture which cushions the piston as it comes to the end of its stroke. Before the lower edge of the piston reaches ports L, the exhaust valve in the lower end of the cylinder is opened by bell crank K actuated by cam R. This relieves the pressure of the exhaust gases so that the mixture in space M, which is under slight compression, may force all of the exhaust gases out through the valve when the piston uncovers the ports on its upward travel.

The weight of the moving parts now causes them to descend, the exhaust valve closing at the same point as it opened, so that the fresh charge is compressed to a pressure of about 200 lbs. per sq. in., thus acting as a cushion to stop the moving parts. At the lower limit of travel, ignition of the charge is effected by a contact maker U, by altering the position of which it is possible to shorten the stroke, the absence of any revolving parts removing the possibility of danger due to pre-ignition where there is a dead centre. A rubber buffer S on the top of the cylinder prevents damage should leaky valves or other causes allow the weight to descend too far. In the larger pumps of this type the cylinder head telescopes into the weight and cushions on the enclosed air.

The starting of the pump is done by a barring lever acting underneath the cross-head, which forces the parts up till the mixture in space M has access to the cylinder. When the lever is released the moving parts fall and commence their functions, as already described.

These pumps can be operated on artificial gas, producer gas, or gasoline, and are being adapted to paraffin and heavy oils. The 3-in. pump shown can deliver 9,200 gals. per hour against a head of 8 ft., and with suitable water end will operate against a head of 172 ft., delivering 575 gals. per hour. The gasoline consumption is five-eighths of a pint per hour, and the weight 350 lbs.

IT is estimated on fairly reliable although not official information that in England 27,000 men are engaged in building heavier-than-air flying machines. In addition, there are men engaged in building auxiliary equipment such as magnetos and carbureters. It is no exaggeration to say that in Great Britain alone about 40,000 men are now engaged in aeroplane work. It is stated in Germany by well informed people that the English factories have an output of 140 machines a week. The French factories are doing their part; several plants in the United States and Canada are doing theirs. In Germany four big factories have been turned over to aeroplane building, among them one of the largest plants of the Allgemeine Elektrizitats Gesellschaft.

EXPORT TRADE DEPENDENT ON A MERCHANT MARINE

TO effectively develop and maintain any worth-while export business, something more than the ability to secure orders and possession of the necessary manufacturing capacity are required. It is for the most part overlooked that prompt and dependable transportation facilities should be available, also that their control be in the nature of a domestic, and not foreign, vested interest. Concurrently with the preparations to distribute our products of the field, the mine and factory over the markets of the world, strenuous effort should be made towards the creation and upbuilding of a powerful merchant marine, the individual constituent of which would be of Canadian manufacture and Canadian manned.

While it is probably true that even if we had possessed a fair sized fleet of Canadian-owned sea-going ships, many of them would in the past month have been commandeered and few, if any, would even now have been available for our export requirements, yet we do not get away from the fact that we have been dependent for ocean transport on foreign built and foreign owned vessels. Again, unless some real action is now taken we will be just so much more at the mercy of foreign shipowners as will make well-nigh impossible an export trade worth the name.

It is not realized that Canada's possession of a merchant marine of the greatest possible proportions will furnish the basic stimulus to her industrial development in both domestic and foreign markets, and that while its revenues will be altogether Dominion-accruing, its services and activities need not be Dominion-dependent, but of world-wide scope.

Canadian built, manned and owned ocean-going vessels as the result of Canadian enterprise are the medium through which our farmers, our merchants and our manufacturers can most surely and effectively lay hold of the trade requirements of other countries and in view of the trade war which is generally anticipated when the thirst for blood has been sated, there is little doubt that those countries with the more ample ocean transport will reap the more ample benefit.

We have neither controlled shipbuilding plants nor are any measures in force or likely to be so, prohibiting their further establishment. We are, however, lacking first of all in vision, and as a natural result, enterprise is also lacking. It may not, however, be inferred that everybody is asleep, so to speak. Here and there bright and keen minds are alert and active, and if we judge rightly their numbers are increasing and their influence is becoming more powerful and wider in scope.

In spite of the fact that recruiting has in some measure restricted the output of coal from the mines in the Maritime Provinces, the reduced quantity cannot be shipped for want of "bottoms." As a result, the City of Montreal with its myriad factories is dependent to a large extent for its fuel supply from American centres, via, lake and canal waterways. Such a condition ought not to exist one day longer than necessary, and its remedy like that of the preparation for prosecuting Canadian export trade on sane and business-like lines lies in our creation and developmet of an ocean port and waterway shipbuilding industry. The more intensely the latter is propagated and the more firmly established it in time becomes, the more sturdy will also be the growth of a seafaring community.

The creation and establishment of even a moderate-sized shipbuilding plant involves considerable capital investment, outstripping in this respect most specialized industries. The scope of its product is correspondingly wider, and as a developer of other industries and crafts it is without a peer. Cost of production—labor cost comparatively, has always been urged as a good and sufficient, and possibly the only reason, why shipbuilding should not be encouraged on our shores. Government after government have taken up this attitude, and strange to relate, when comparative costs may be said now to synchronize, and merchant shipbuilding in the world's premier centre has for obvious reasons and during many months, been reduced to an absolute yet undesirable minimum, the present administration still busies itself casting about for excuses to bolster up an untenable position, instead of bringing to the subject the measure of intelligence and consideration it deserves, and taking a hand in formulating a basis of national support.

WOMEN MUNITION WORKERS

THE recent action of representative Canadian manufacturing concerns in arranging to employ a considerable number of women on shell work serves to emphasize a feature of the labor situation which so far has not affected our manufacturing interests acutely enough to make the results apparent to the general public.

While the entrance of women into the ranks of munition workers in Britain was accepted as a matter of course, being only one of many necessary developments under the present circumstances, a considerable variety of opinion existed regarding their suitability for much of the work of producing munitions, but published accounts show that their ability has not only enabled many of them to surpass male operators in performance, but has led to their employment on general machine construction and tool room work with a degree of success which is surprising.

Where the introduction of women workers in a machine shop is an entire innovation, the matter has to be handled carefully to insure the full amount of success. A significant feature of the situation is indicated by an English correspondent of a contemporary. Regarding a prominent machine builder he says: "No young girls are employed. The women engaged are those who enter the factory with a serious purpose and have homes to keep. Several widows of men who were previously employed in the same shops and have been killed in the European War are included." Shell making in Canada is a tense occupation, and if events demand the more general employment of women, employers will only be doing their duty to the themselves, their community and their country by so selecting and paying their help, that the greatest good will be done to the greatest number while they themselves may in some cases derive the greatest benefit of all.

INDUSTRIAL NOTABILITIES

WILLIAM DONALD ROSS, Vice-President, Nova Scotia Steel & Coal Co.; director, Bank of Nova Scotia; director, Porto Rico Railways Co., was born at Little Bras d'Or, N.S., on June 20, 1869, the son of John Ross and Isabella Mackay.

He was educated in the Public and High Schools of New Glasgow, N.S., and entered on his business career by joining the staff of the Bank of Nova Scotia in 1883. His connection with that institution was unbroken until 1901, he having in the interval filled successively the positions of manager at Stellarton, N.S.; assistant inspector at head office; manager, New Glasgow; and manager at Charlottetown, Prince Edward Island.

WILLIAM DONALD ROSS.

During the years 1901-1902, Mr. Ross was chief clerk in the Finance Department at Ottawa. In the latter year he became assistant general manager of the Metropolitan Bank at Toronto, being appointed general manager in 1903, and serving in that capacity until 1914.

He successfully conducted the negotiations towards a merger of the Metropolitan Bank with that of the Bank of Nova Scotia. He is a councillor of the Canadian Bankers' Association, and in matters financial generally, his advice and co-operation are largely in request.

As a director and later as vice-president of the Nova Scotia Steel & Coal Co., the scope of Mr. Ross' activities have been very materially enlarged, and more especially so when account is taken of the extent to which that concern has thrown itself into the successful manufacture of munitions, rolling stock and steel products generally as a result of the war.

His clubs are the Toronto, Ontario, York, Toronto Hunt, and the St. James, Montreal. In religion he is Presbyterian. His home is at 112 St. George Street, Toronto, Ont.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., June 26, 1916.—The general industrial situation continues active. The majority of plants, however, especially those working on munitions, are busy, and many factories are being extended to accommodate additional equipment. One of the serious features is the scarcity of labor, which tends to curtail the output, and, as the summer advances, this is expected to become more pronounced. General opinion seems to be that the apex of the market in prices of raw and semi-finished materials has been reached, but it is not expected that any appreciable decline will be shown for some time.

Pig Iron

The situation in pig iron is unchanged, with a heavy demand for steel purposes the chief feature. Inquiries for foundry pig are better; this may be accounted for by the prospect of an easier market. Philadelphia prices on No. 2 foundry show a decline of 25c a ton, and low phosphorus pig has declined $1 a ton.

Steel

Domestic demands have fallen off a little, but export requirements more than make up for any loss in this direction. Increased demand for open-hearth steel has somewhat steadied the market and quotations are becoming firmer. Lower prices on spelter have affected the market in sheets, and some lines have been reduced. Queen's Head is now $7.50; Fleur-de-Lis, $7.25; Premier No. 28, $6.75, and Premier, 10¾ oz., $7.10. Iron bars are fairly active, and the Chicago price shows an advance of $2 a ton. Railroad spikes, Chicago, are higher, latest quotations being $2.75, or an advance of $2.50 a ton. Pittsburg quotations on cold-rolled shafting have declined, the discount being 20 to 15 per cent., against 15 to 10 a week ago. Demand for wrought iron pipe and boiler tubes is not heavy, but prices are very firm.

Metals

The general tone of the metal market is inclined to weakness. With the exception of aluminum, very little activity is shown, and continued declines have met with little response from buyers. Copper is being offered at easier prices. The foreign situation has weakened the tin market here. Lead is steadier, but spelter is attracting little notice.

Copper.—The present condition of the market is very quiet, and little activity is shown in regular business. Owing to the Mexican situation it is anticipated that some copper mines may be affected by existing conditions unless provision is made to protect the mines in the disturbed locality. It is expected that the market will retain its present level, or possibly a little lower, until further buying on a large scale develops. London reports additional weakness, the decline for the week being £15 on standard spot; £14 on futures, and £10 on electro spot. Selling of metal is on the increase, and producers are offering easier terms on next quarter metal. Latest quotations are £98 for standard spot; £96 for futures, and £130 for spot electro. Light inquiry and resale of consumers' copper has resulted in the New York prices declining; lake and electrolytic showing a decline of ⅝c, are now quoted at 26⅞c, and castings at 24¼ show a decline of 1c per pound. The market here continues quiet, and dealers report a decline of 1c on all coppers, quoting 31c for lake and electrolytic, and 30c for castings.

Tin.—Dullness prevails, and the trade continues very quiet, and unless early buying develops, it is expected that further declines will be quoted. London quotations continue to weaken, and lack of interest and slight buying have been followed by further weakness on the New York market: the nominal price of 40¼c being a decline on the week of 1½c per pound. Local dealers report a quiet market on declining prices; present quotations of 47c show a decline of 1c.

Spelter.—The present market is dull and weak. Very little metal is being purchased by galvanizers, but their requirements will likely develop into buying as soon the market assumes a more steady tone. London and New York markets continue dull and inactive, the

nominal price of 12.175c being 1c lower than a week ago. The local situation is unchanged, with prices easier. Dealers are asking 16c, being a decline of 1c per pound.

Lead.—The situation in lead is practically unchanged. Export inquiry is better, but so far purchases are light. The outside interests have advanced their price from 6.8c to 6.9c per lb. Local conditions are unchanged, and dealers here are quoting 9c per lb.

Antimony.—The market continues dull, and additional declines do not appear to interest buyers. New York prices have declined 1½c, and dealers here are quoting 30c, which is a decline on the week of 1c per pound.

Aluminum.—Foreign inquiry and buying is adding strength to aluminum; prices have remained firm; New York is quoting 63c to 65c, and dealers here are asking 66c per pound.

Machine Tools and Supplies

Owing to recent additional orders being placed for large shells, the demand for equipment has slightly increased: but the delivery on standard equipment is almost normal.

Scrap

Dealers report a fair business, but a weak market, quoting 1c less on copper, ranging from 16c for light to 19½c for heavy, and 19¾c for wire. No. 1 compositions have declined ¾ of a cent, and are now quoted at 13c. Rails, shafting and wrought iron pipe show a decline of ½c, quotations being 13½c, 16½c and 11c respectively. Old stove plate is a little stronger, an advance of ½c making the present price 11c per pound. Scrap zinc is quoted at 11c, being a decline of ½c per pound.

Toronto, Ont,. June 27.—The steady improvement in trade throughout the country is being well maintained and the outlook continues favorable. Railway earnings this month are showing a marked increase over the corresponding period of last year which is a good indication of the general trend of business. The financial situation has also improved considerably, particularly because of war orders which have resulted in a large amount of money being distributed in the country. The greatest activity still prevails in munition plants, and machine tool manufacturers both large and small are very busy on this account. The steel trade is quieter as is usual at this season. The steel market continues firm although indications point to prices having about reached the top. No marked recession however, is anticipated for some time to come. The weakness in the ingot metal markets continues and further declines have to be noted this week.

Steel

The usual summer dullness prevails in the iron and steel market. The new demand is lighter and the upward movement seems to have come to a definite stop. Although the mills are sold up for the remainder of the year and on some lines have booked considerable business for delivery towards the end of the first quarter of 1917, consumers are hesitating in placing new contracts as they are looking for a possible decline in prices. The market is easier as a result of the big increase in the capacity of the mills, this circumstance having a tendency to lower prices. No marked recession however is anticipated for some time to come as no material falling off in either export or domestic demand is expected for many months. Even after the war, it is very probable that there will be a brisk demand for steel products from all sources. There are no price changes of importance to note this week except that iron bars have moved up to the level of steel bars at $3.25 per 100 lbs. The new demand for boiler tubes is not so urgent, as nearly all consumers are covered for some time ahead. The wrought iron pipe market is quieter as the amount of new business has fallen off. Prices of skelp, however, are very strong, the mills being sold up for three or four months ahead. Shafting is firm and still high in price, most consumers being covered over the remainder of the year and makers are largely sold up for that period.

The sheet market is quieter but abnormal conditions preclude any weakness developing owing to the shortage and increasing price of sheet bars. The demand for black sheets is lighter but this is offset by decreased production and with the differential between costs and selling prices steadily disappearing no weakness in price has developed, Blue annealed sheets are in good demand. The decline in spelter has not as yet affected the price of galvanized sheets in the local market although quotations are lower in the States. Galvanized sheets are however moving more freely although the output is still far below normal. The recent declines in the price of spelter have developed irregularity and uncertainty in the market for galvanized sheets which may lead to lower prices.

The steel market is easier in the States but the quietness is not affecting prices. The new demand is lighter but export business continues very heavy, particularly for steel bars and railway material. Considerable strength is given to the situation owing to the mills being sold up for practically everything during the remainder of the year. Steel bars are unchanged at 2.75c, plates 3.75c, and shapes 2.50c, Pittsburgh. Bessemer billets have declined $2, and are now quoted at $42 while open-hearth billets and sheet bars have recovered and are now back at $42 per ton Pittsburgh.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Scrap

The scrap market continues quiet and quotations have a weaker tendency. Scrap copper, machine composition, and brass have declined but aluminum is higher. Heavy melting steel is firm but unchanged. The demand for metals for munitions continues heavy but ordinary business is dull.

Machine Tools

The situation in the machine tool market is much the same as last week. Some nice orders for equipment for machining large shells have been placed recently while others are pending. Large swing lathes are in good demand and a number of enquiries have been received by local dealers for heavy duty drills, grinders and cutting-off machines. Standard equipment is in fair demand, the orders being principally for single tools. Deliveries are much quicker especially on the large lathes.

Supplies

Business continues good, the activity in the munitions plants being reflected in the demand for machine shop supplies. Prices generally are firm and steady, advances now being fewer and less frequent. An advance on some of the Butterfield Co. products are now in effect. The following are a few of the new discounts: Reece screw plates, 15 per cent.; dies 10 per cent.; taps up to 1 in 50 per cent.; and over 1 in., 35 per cent.; collets, stocks and caps 10 per cent.; Derby stocks and dies 20 per cent.; stock and dies 10 per cent.; stocks and collets 10 per cent.; hand taps 1-16 in., to 15-64 in., 60 per cent.; ¼ in., to 1 in., 50 per cent.; and 1 1-16 in., to 2 in., 35 per cent. Linseed oil has again declined and is now quoted at 70c and 73c for raw and boiled respectively. Gasoline is unchanged and it is believed that prices will not go any higher. A decline in white lead is considered probable in the near future.

Metals

The metal markets continue weak with quotations still declining. Although the demand for metals for munitions is still very heavy, production has increased and has caught up with the consumption which naturally tends to weaken the position of the metals involved. Copper and aluminum have shown less tendency to weakness than other metals, and will probably remain around the present levels. Developments in the Mexican situation will probably affect copper and tend to strengthen the market, although there is no evidence of this as yet. Tin is weak following a decline in London, and the market continues easy. Spelter has also declined and the market is weak with consumers awaiting developments. Lead has still a weak tendency but quotations are unchanged. The demand for antimony is dull and the market unsustained with quotations lower. Aluminum is strong and higher due to improved demand and scarcity of supplies. Solders have declined due to weakness in the tin market.

Copper. — The market is being depressed by second hands who continue to make concessions and it appears likely that the market will remain in the present condition until a new buying movement develops. The Mexican situation is being considered, but so far the market has not been affected to any noticeable degree. A war between Mexico and United States would mean cutting off supplies of copper from the former country which would no doubt result in a reaction in the market and higher prices. Copper is a shade weaker locally and quotations are entirely nominal at 30½c per pound.

Tin.—The market continues weak following a decline in London. Buyers are showing little or no interest in the metal and appear to be awaiting developments. The local market is quiet and lower at 47c per pound.

Spelter. — The market is dull and weak following a decline in London. The market continues in the hands of second sellers who are willing to sell at concessions. Most of the producers however, are not making any effort to secure business at prevailing levels. Locally quotations are lower at 16½c per pound.

Lead.—The market is a little firmer at unchanged quotations in New York but weaker in London. Business is more active and indications point to a considerable amount of lead being sold in the near future. The Trust price of 7c New York is well held, with the outside market showing a slight advance to 6.95c New York. Lead is unchanged locally at 9c per pound.

Antimony.—The market is dull and weak with light demand. Although it is reported that small consumers have been buying; the larger consumers show no interest in the market at present. Local quotations are lower and nominal at 30c per pound.

Aluminum.—The market is firm and active due to increased demand and scarcity of metal. Quotations are higher at 66c per pound.

Solders.—Prices have again declined following the weakness in the tin market. Guaranteed is now quoted at 29½c and strictly at 27½c per pound.

RUSSIAN MARKET FOR ELECTRICAL SPECIALTIES

THAT Russia will be one of the most important markets for electrical goods after the war is generally recognized, and if advantage is going to be taken of the hostility to German wares which will prevail for a long period after the war, even if no prohibitive tariff is put in force, should be at once taken to ascertain the particular requirements of this great market. Information relative to the above appears in all the official reports dealing with trade prospects in the territory of our Ally.

The last official to lay stress on the importance of doing something at once is the British Consul at Batoum. He points out that before the war the electrical goods required in the Caucasus were mainly of German origin. There is said to be such a great demand from this district that American and other manufacturers are already giving close attention to the local requirements, but that if the opportunity is not allowed to slip there is no reason why Canadian sources of supply should not also be tapped.

Stress is laid on one or two special points; the need for a close study by British houses of the question of price and terms of payment; also on the importance of being represented by travellers who speak Russian, and who carry Russian price lists with the prices worked out in roubles at the current rate of exchange. These are hints which apply not merely to the Caucasus, but to the whole of the Russian market, and it is hoped they will be taken to heart.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian. — Col. N. Golejewski, Military Attachè, Room 904 Flat Iron Building, New York City.

DOMINION STEEL CORPORATION

THE future policy of the Dominion Steel Corporation was outlined by President Mark Workman at the annual meeting of shareholders held in Montreal on June 20. After reviewing the year's operations, Mr. Workman stated that, following a personal investigation, he was of opinion that the company's coal department was equal to any on the continent, but that in order to successfully compete in the world's steel markets, after the close of the war, improvements at the steel plants were necessary.

Remodel Blast Furnaces

Mr. Workman advocated such improvements being made from earnings. In fact, he announced that the first step in the new policy of reducing costs and securing the utmost efficiency from the steel plants had already been taken. This consisted of the remodelling of two of the oldest blast furnaces on the most approved modern lines. As the furnaces had reached the stage where reconstruction was necessary in any event, the work to be carried out would not entail a serious extra expenditure. It was his desire to carry out the same policy throughout the entire steel plant. At the present time more of this work could be started, were it not for the scarcity of labor and the high cost of raw materials. The labor situation at the plants was satisfactory, but all of the company's employees were actively engaged in production, and, therefore, not available for the work of reconstruction. Mr. Workman said that the prospect of satisfactory business throughout the current year justified the belief that the company would be able to undertake the contemplated changes in the near future.

Board Re-elected

At the meeting only one question was asked, a shareholder inquiring as to the company's unfilled tonnage. To this Mr. Workman replied that the company's output until the end of the year had almost entirely been disposed of. Apart from this, the meeting was of a routine nature and lasted only fifteen minutes. The annual statement was adopted and the board of directors re-elected. At a subsequent meeting of directors George Caverhill was added to the executive committee. The vacant vice-presidency created by the death of the late Sir Wm. Van Horne was not

filled. There are now three vice-presidents—Wm. McMaster, of Montreal, and Sir Henry Pellatt and Col. Frederic Nicholls, of Toronto.

RUSSIAN TRADE TO VANCOUVER

AT a luncheon of the Council of the Board of Trade, held at the Hotel Vancouver recently, Constantin Ragosine, Russian Consul in Vancouver, was the chief speaker, his address dealing with the future trade relations between Canada and Russia, and the important part which he believed Vancouver would play by reason of its position as the chief Canadian seaport on the Pacific.

To Oust Germany

Respecting trade relations between the two countries after the war, Mr. Ragosine said: "To be more precise in describing the interest of Russia in the importation of Canadian goods, I can say I expect from it the liberation of the Russian market from the industrial monopoly of Germany, and which at the same time will bring to the Russian consumer a wider and better choice of goods."

For Western Siberia in particular, he believed, the advent of the Canadian merchant and manufacturer to be desirable, since they would bring with them the technical knowledge and machinery necessary to the development of Russian resources. The position of Vancouver in relation to Vladivostok, he considered, was excellent, and made it possible for goods loaded in Vancouver to be transferred direct to Russian hands.

He predicted that Vancouver would become in time the port through which much of the produce of the United States, as well as Canada, would be handled, and stated it as his belief that the citizens of Vancouver should be fully alive to the great opportunity which he believed lay within their reach.

Mr. Ragosine said that shortly a bureau of information concerning all things Russian will be established in Vancouver for the convenience of merchants, manufacturers and the general public. He laid special emphasis on the necessity of British people acquiring a knowledge of the Russian language, which, he said, was not so formidable as it might look in print. To the way in which they had applied themselves to learning the Russian language he attributed the great influence of Germany in the industrial life in Russia.

United States on Job

He advised a Canadian speaking the Russian language to be placed in the bureau, which he considered should be equipped with a complete set of books dealing with every department of Russian commercial life and law. In all this work he expressed his desire to assist to the utmost of his ability. Speaking of the wide-awake attitude of some American manufacturers with respect to Russian trade, he stated that railway officials from Seattle were at this time over in Siberia studying the needs of that country on the spot.

Mr. Ragosine's address was followed with the closest interest and was accorded a generous measure of applause at its termination.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

Engineering

Hamilton, Ont.—M. Brennen & Sons are in the market for wood-working machinery.

St. Thomas, Ont.—It is reported that the Wabash Railroad will build repair shops here.

Lindsay, Ont. — The G.T.R. propose building a roundhouse, machine shop, etc., to cost $20,000.

Toronto, Ont. — Canadian Allis-Chalmers, Ltd., will build an addition to their factory to cost $6,000.

Ottawa, Ont.—Peter Lyall & Sons Construction Co., are building a frame workshop here, estimated to cost $35,000.

Chesley, Ont.—Two dams near the M. A. Halliday power plant were recently badly damaged as a result of heavy rains.

Parry Sound, Ont.—An explosion on June 21 destroyed No. 3 charging house at the plant of the Canadian Explosives, near here.

St. John, N.B.—The C. P. R. will erect a new 20,000-gallon water tank to furnish a reserve supply for locomatives and for fire fighting.

Collingwood, Ont.—F. Kent and J. A. Sinclair are interested in a company recently organized to manufacture wood and metal specialties.

Toronto, Ont.—The Dodge Mfg. Co., will erect a garage and addition to machine shop at this factory here. The cost will be about $1,800.

Outremont, Que.—Plans have been prepared and accepted by the City Council, for a reinforced concrete community garage, to cost $50,000.

Merlin, Ont.—Natural gas has been found here in considerable quantity by the Southern Ontario Gas Co., who are conducting the drilling operations.

Toronto, Ont.—Work on the addition to the civic barns on Bracondale avenue, for which the permit was recently issued, has commenced. It will cost $21,000.

Welland, Ont.—The Standard Steel Construction Co. have leased the Dominion Canners Co. factory at Port Robinson, and will equip the building as a machine shop.

Cobalt, Ont.—Nipissing Refinery, attached to the high-grade mill, the largest silver refinery in Canada, was gutted by fire on June 21. The damage is extensive and refining of bullion will be prevented for some time.

Medicine Hat, Alta.—The Alberta Foundry & Machine Co. will build an extension to their plant, to cost about $20,000. The new building will be of brick construction, 160 ft. by 120 ft., and will include an iron foundry and machine shop.

Hamilton, Ont.—The Canadian Cartridge Co. has started work on a large addition to its factory on North Sherman Avenue. The building permit has been issued, and calls for a structure, costing $20,000, to be erected by the George Frid Contracting Co.

Oshawa, Ont.—The by-law to fix the assessment of the McLaughlin plant was carried here last Monday by a large majority. It is expected that a large addition to the plant of the Chevrolet Co., will be commenced immediately, which will be constructed to take care of the domestic trade and also with a view to future export business.

Large Power Plant Project.—It is understood that plans will shortly be prepared for the construction of a new municipally-owned hydraulic power plant by the City of Montreal, the cost of the latter, including equipment, being in the neighborhood of one and a half million dollars. Contracts for the buildings and equipment are expected to be placed during the coming winter. The projected installation is in connection with the new aqueduct scheme.

Montreal, Que.—It is understood that the directors of the Wayagamack Pulp & Paper Co. are considering the erection of a sulphite mill to be operated in conjunction with the plant at Three Rivers. The estimates received by the company would indicate the cost of the proposed plant at from $1,000,000 to $1,500,000. Plans in connection with the proposed expansion are said to be fairly well matured, and unless some new development occurs announcement regarding them will be made in the near future.

Renfrew, Ont.—Engineer Kribs, of the Hydro-Electric Commission, has sent a report to the Town Council respecting the investigation of power possibilities made by him for Renfrew at the first and fourth chutes of the Bonnechere River. He finds that at the first chute 1,500 h.p. can be developed, and at the second, 2,000 h.p. The cost of development and delivery in the one case would be $200,000, and in the other, $300,000. Each chute is located within a few miles of Renfrew, which is in pressing need of more electric power.

General Industrial

Toronto, Ont.—L. White & Sons, will make an extension to their factory to cost about $4,000.

Toronto, Ont.—The Hamilton Carhartt Co., have obtained a building permit for a three-storey brick addition to their factory, 535 Queen east to cost $4,000.

Fergus, Ont.—Work is being pushed ahead at the Superior Barn Equipment Co., property, formerly the cold storage plant, near the Grand Trunk station.

Chatham, Ont. — Tenders are being called for the erection of an addition to the American Pad & Textile Co. factory. Adams and Adams of this city are the architects.

Fergus, Ont.—Beatty Bros., Ltd., are making an extension to their premises at St. David Street bridge. When the alterations are completed it will give them 7,000 square feet more floor space.

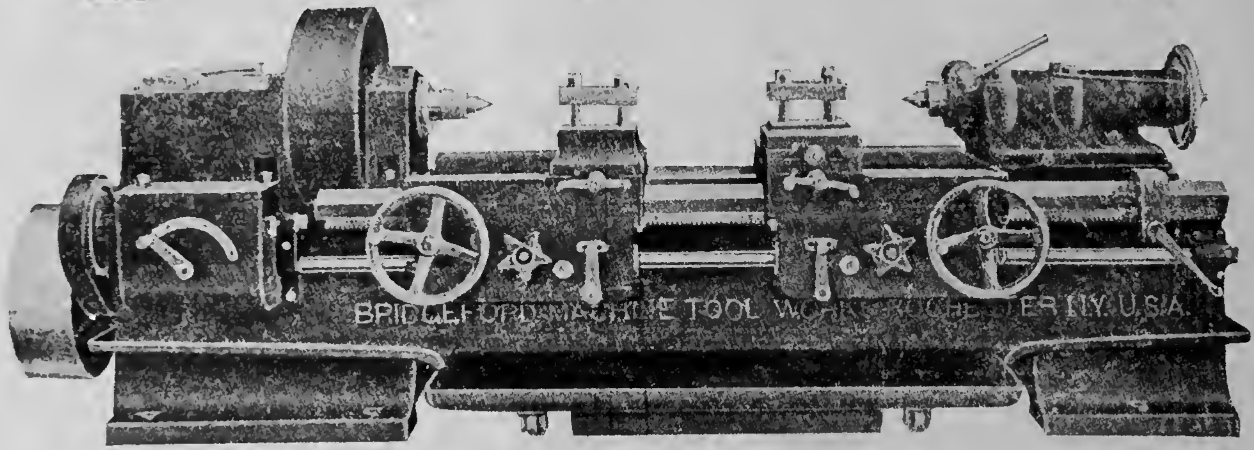
Berlin, Ont.—The Carbo Corporation of Chicago, Ill., will establish a branch here for making steel fence posts. The Nyberg property on King Street East has been secured and building operations will commence shortly.

Toronto, Ont.—Construction work has been commenced on the erection of a new grain elevator by the Campbell Milling Co. on Cawthra street. A building formerly used for rolling grain has been dismantled and removed. Excavation work has been done for the structure. It will cost $10,000.

Brantford, Ont.—The Hampel Paper Box Co. of this town in which Messrs. G. Turbull and G. Hancock, of the Galt Paper Box Co. are associated with W. G. Hampel, manager of the Brantford plant, have decided to erect a new modern box factory here.

Niagara Falls, N.Y.—The McGlashan—Clarke Co. are having a large addition built to their factory at the corner of

The A. R. WILLIAMS MACHINERY CO., Limited



"BRIDGEFORD" 27-in. HEAVY DUTY LATHE

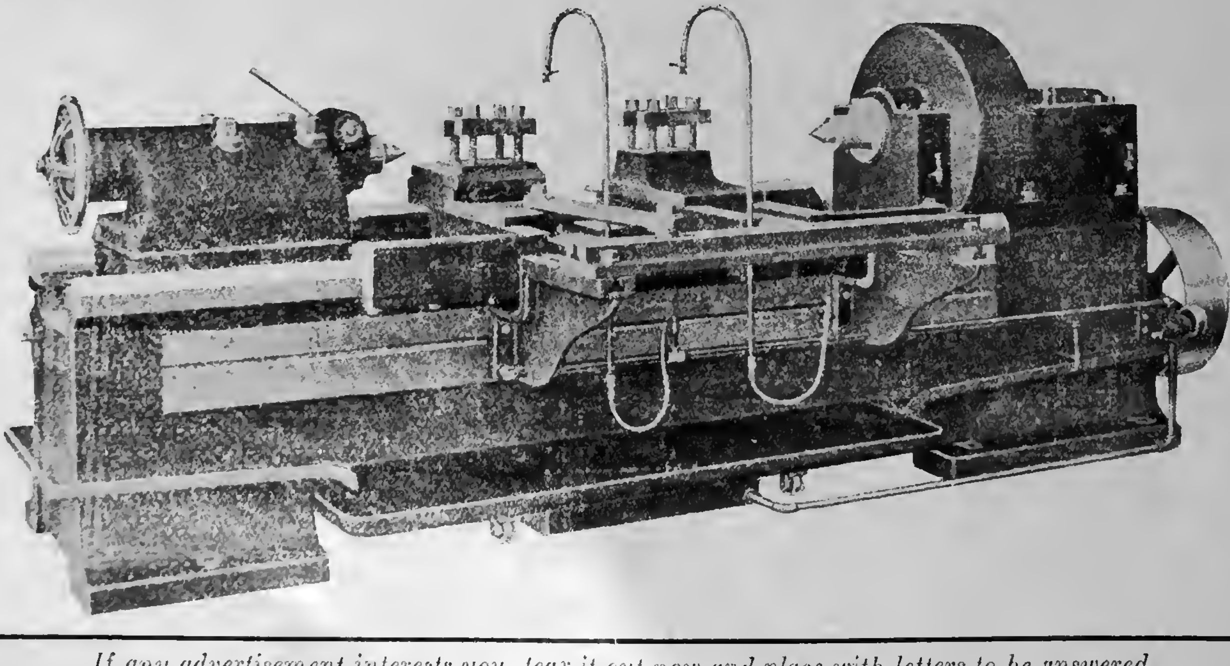
The Ideal Machine for Rough-Turning Shells

This is an especially heavy duty machine, and as shown in the engravings, is arranged for rough-turning 8", 9.2" or 12" shells. Power is transmitted through 8" driving belt, with three instantaneous speed changes through hardened steel gearing. Main driving gear 6½" face. Four instantaneous feed changes—all through cut steel gearing, running in oil. Leading shell manufacturers have from 70 to 120 of these machines in operation—giving remarkably satisfactory results.

Owing to greatly increased facilities, we can make early deliveries on Bridgeford lathes. Write us.

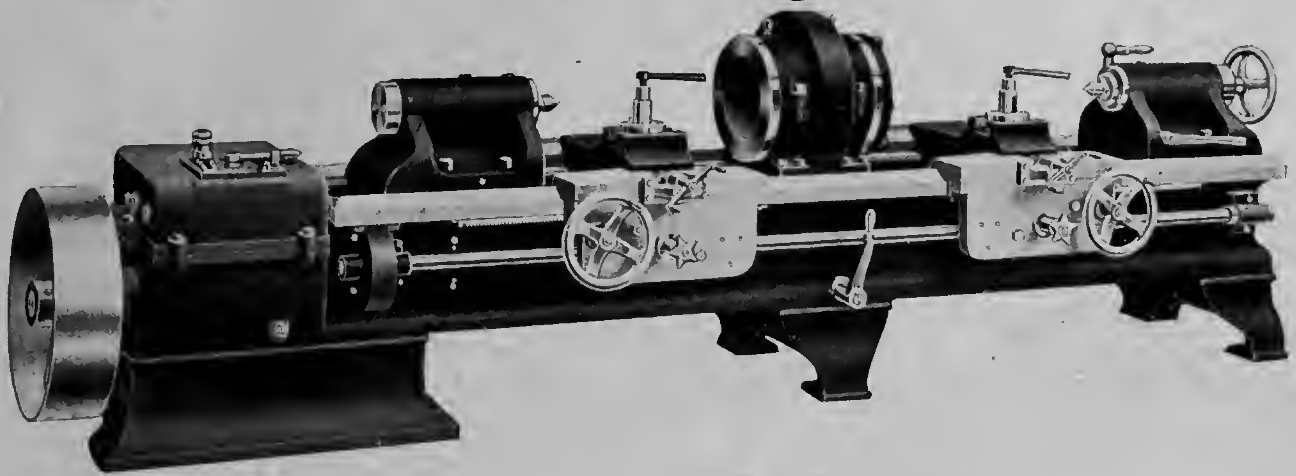
BRIDGEFORD MACHINE TOOL WORKS, 237 Mill Street ROCHESTER, N.Y.

Sales Agents: The A. R. Williams Machinery Co., Limited, 64-66 Front St. W., Toronto



THE A. R. WILLIAMS MACHINERY CO., Limited

The Bridgeford Engine Lathe for Finish Turning



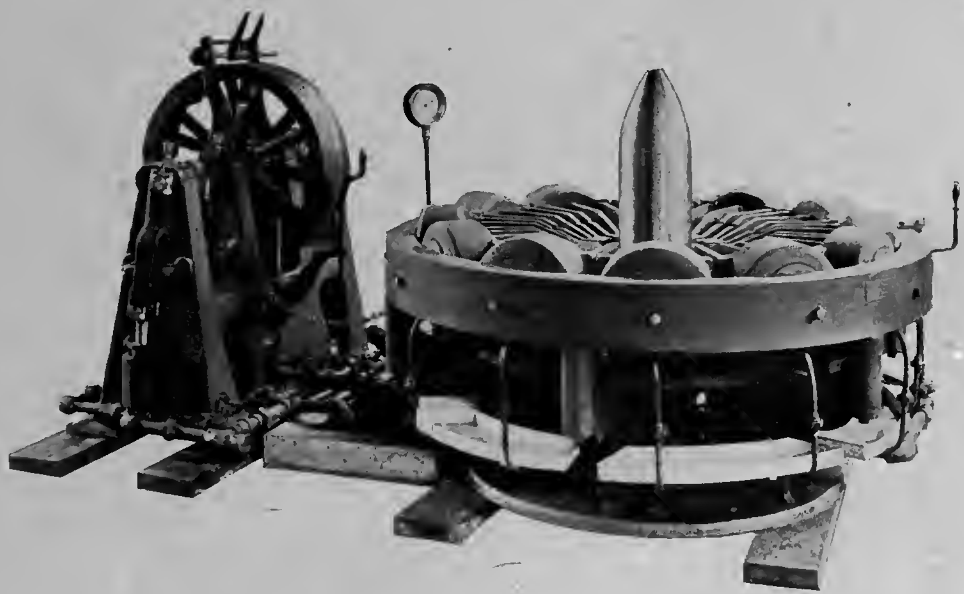
The Bridgeford Double End Machine with adjustable Tailstock at each end is specially adapted for this operation. It is equipped with Compound Tool Slides with European Tool Posts (not illustrated).

The Bridgeford is also equipped for Boring operations and was originally specially designed for this purpose.

Write for illustrated Bulletins giving full data on Bridgeford lathes for Boring, also Rough and Finish Turning.

Sales Agents: The A. R. Williams Machinery Co., Limited, 64-66 Front St. W., Toronto

BIG SHELLS, TOO



FOR compressing bands on shrapnel and high explosive shells there is no more efficient machine built. It is rapid, reliable in operation, and turns out work in strict accordance with government requirements.

Machine consists of a series of hydraulic rams set around inside a steel ring mounted on a cast-iron base, and operated by a belt-driven pump. An advantage peculiar to this machine is the special equipment which prevents the edges of the bands from becoming sheared during the banding operation.

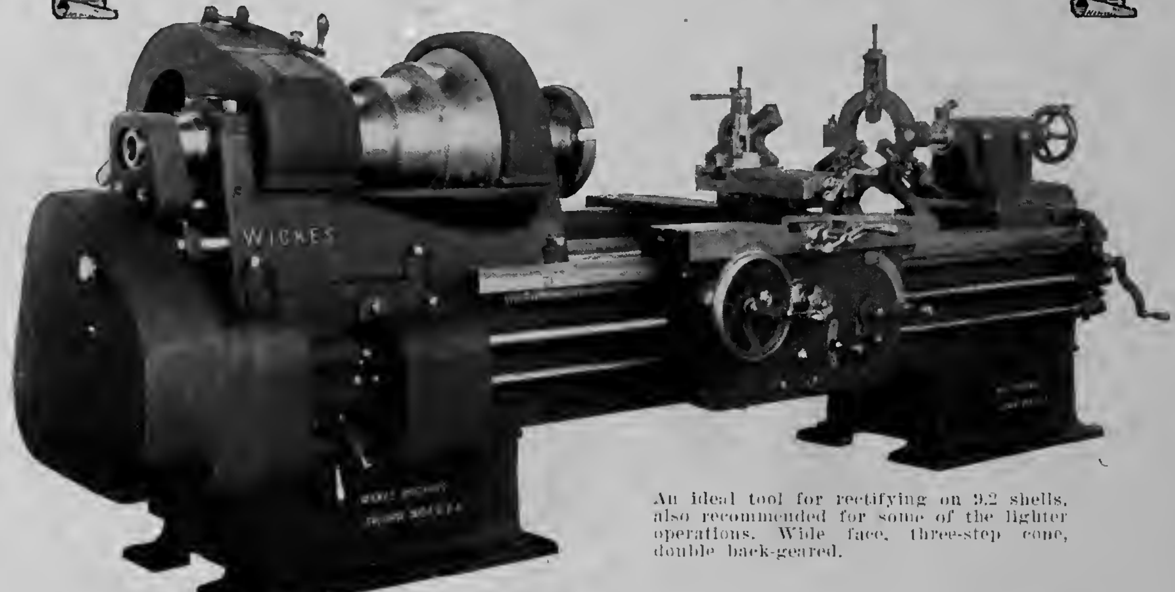
These banding presses are adaptable to a variety of other work, and will make profitable permanent equipment after shell contracts are completed.

West Tire Setter Company, Rochester, N.Y.

Sales Agents: The A. R. Williams Machinery Co., Limited, 64-66 Front St. W., Toronto

THE A. R. WILLIAMS MACHINERY CO., Limited

Wickes 26" Heavy Duty Engine Lathe



An ideal tool for rectifying on 9.2 shells, also recommended for some of the lighter operations. Wide face, three-step cone, double back-geared.

Features—Apron gears, all pinions throughout of steel; English type, 4-stud or compound rest on extra heavy carriage furnished as regular equipment; wide range of thread-cutting and turning feeds. Net weight, 7,700 lbs.; 10' bed; built in 16", 20", 26" and 30" sizes. Write for circulars with full description and prices.

50 years in the game. We know how. **Agents, The A. R. Williams Machinery Co., Limited** **The Wickes Machinery Co., Ltd., Saginaw, Mich.**

Hoskins Furnace for Heating the Copper Band

Hoskins Furnaces are made in Canada and are evidence of Canadian ability to meet unfamiliar manufacturing requirements successfully. The furnace is distinctively a Canadian development and is equal to the best product of foreign manufacture. This furnace is supplied in any size from 4" x 3" x 9" long to 4' x 2' and 8' long. The outstanding features of the Hoskins Furnaces are the temperature control and range from 100° F. to 2000° F., and can be maintained equally, thus eliminating scale. Heating unit is of heavy construction, ensuring long life. Maintenance cost is negligible.

Economy in operation due to construction of chamber which retains the heat. It is cheaper to operate than a gas furnace. Over 2000 in use.

Write for bulletin and get information on capacities, etc.

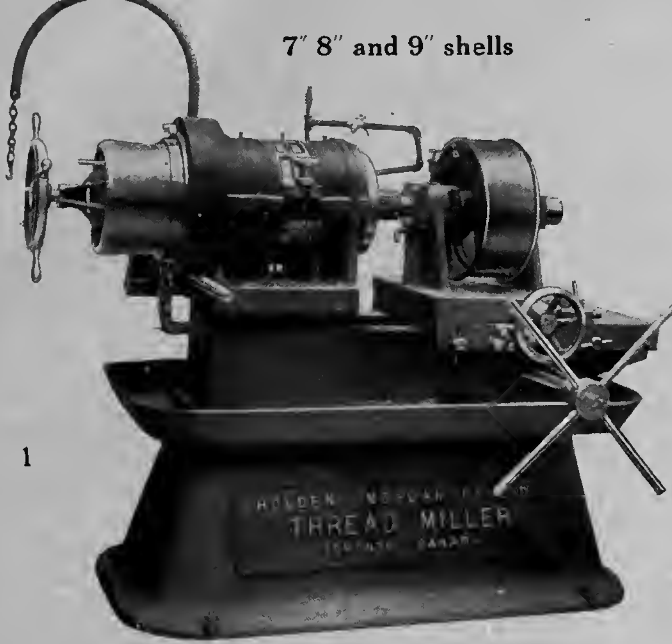
Holden Morgan Thread Millers

7" 8" and 9" shells

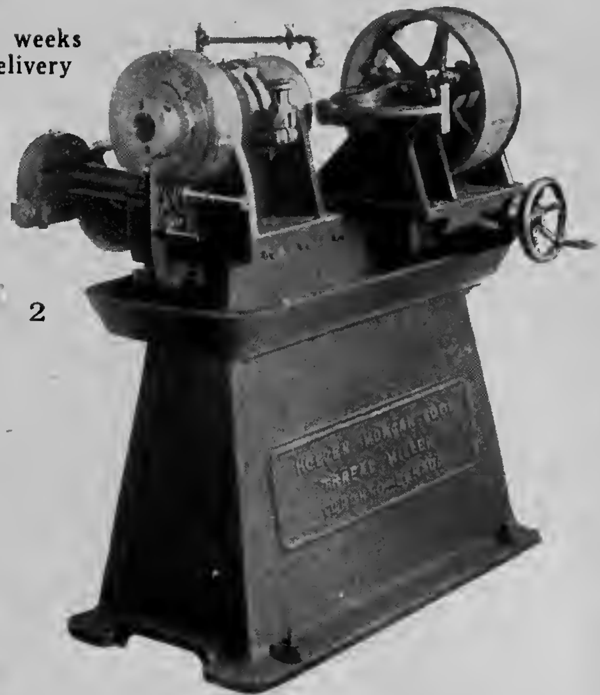


1

The Internal Thread Miller illustrated in figure 1

The shell is carried between two conical surfaces in the interior of the mandrel. This insures the thread being milled perfectly true with the axis of the shell. By this method the shell is held much firmer and truer than by collet chucks. The master screw is chased on the outside of the mandrel, which entirely precludes the possibility of "drunken heads." The milling head is carried in movable carriage and both slides are moved up to positive stops and locked, so that the thread is milled exact.

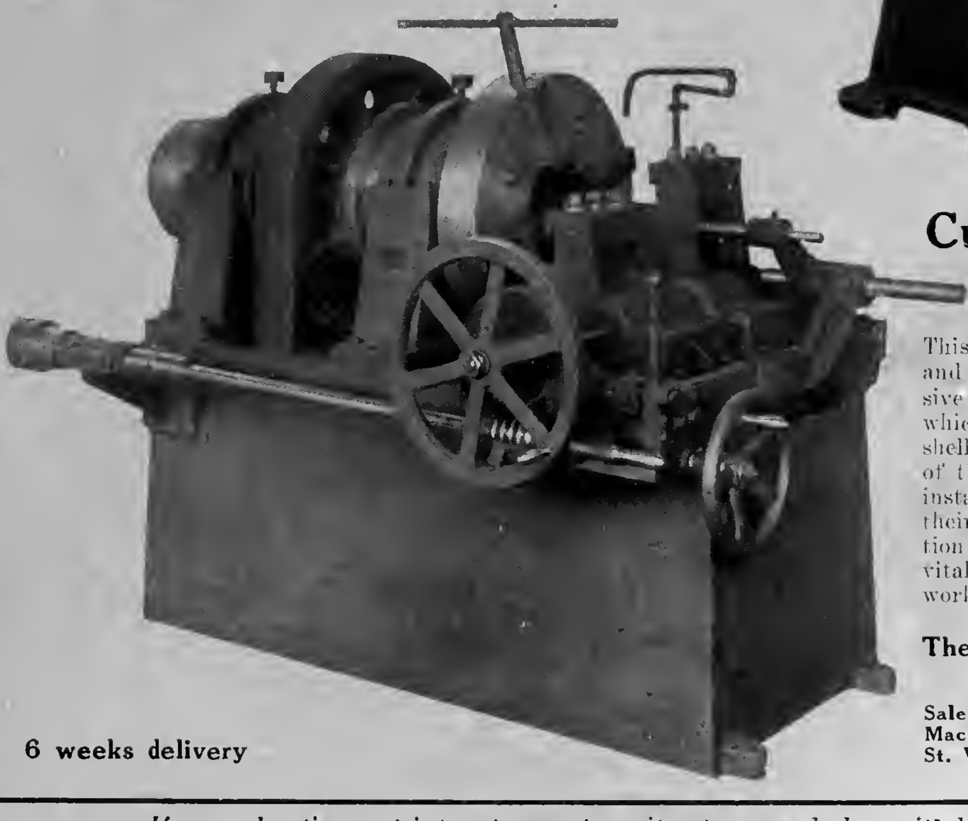
6 weeks delivery



2

The Plug Miller illustrated in figure 2 for 7" to 10" shells

For milling threads on Base Plugs of open Base Shells after being machined. The plug is held perfectly true to the mandrel by a process which can be varied according to the size and type of the plug. The thread is completely milled at one revolution of the mandrel.



6 weeks delivery

Cut-Off and Facing Machine

This machine is made for cutting-off and facing Shrapnel and High-Explosive Shells. The speed and perfection which this machine will cut or face shells from 3" to 12" has induced many of the largest shell manufacturers to install enough of these machines for their requirements. Note the illustration and study the solid build of the vital parts—it's built for work—hard work

64-66 Front St. W., Toronto

We also have for Tool-room equipment, Shapers, Milling Machines, Special Tool Post Grinders and a large variety of labor-saving devices. Consult us about your Tool Room.

Palmer Avenue and Benson Street. The building will be 40 ft. high, 132 ft. long and 44 ft. wide. Except for the curtain walls, which will be of brick, the whole structure will be concrete. Brass Bros. of Niagara Falls, N.Y., are the contractors.

Municipal

Victoria, B.C.—An extension to the water main system is contemplated by the City Council.

Chatham, Ont.—The City Council have decided to call tenders for new equipment for the fire department.

Quebec, Que.—A lighting system will be installed at the Exhibition Grounds here by the Exhibition Commission.

Kingsville, Ont.—A by-law will be submitted to the ratepayers on July 5 to raise $16,000 for the improvement of the waterworks pumping plants.

Burlington, Ont.—The ratepayers on June 16 voted in favor of buying a motor fire truck. The Sherman Auto Garage will supply the equipment.

Orillia, Ont.—A by-law will be prepared to authorize the raising of $110,000 for the purpose of installing three generating units at the new Hydro-Electric plant at Swift Rapids.

Brantford, Ont.—The City Council last Monday gave the third reading to the by-law selling the Grand Valley Railway from Paris to Galt to the Lake Erie & Northern Railway for $30,000.

Stamford Township, Ont.—A by-law will be voted on by the ratepayers on July 10 to authorize an expenditure of $28,000 for the Ontario Distributing Company's equipment in Stamford and Niagara Townships.

Sarnia, Ont.—The City Council has decided to spend $5,000 upon three experimental infiltration basins for the waterworks plant. The basins will be 18 ft. long, 12 ft. wide and 10 ft. deep. Waterworks engineer, James Turner.

Point Edward, Ont.—A by-law will be voted on by the ratepayers on July 3, to authorize raising $7,000 to be used towards the purchase of that part of the distribution plant taken over by the City of Sarnia and within the limits of Point Edward.

Trade Gossip

Orillia, Ont.—The Town Council have awarded a contract to the Boving Hydraulic & Engineering Co., Lindsay, Ont. for three water turbines to cost $29,300.

The Taylor Engineering Co., Vancouver, has secured a contract for six fuel oil engines made by Bollinger, of Stockholm, Sweden, to cost about $95,000.

Jas. H. Mathews & Co., Pittsburgh, Pa., manufacturers of all kinds of making devices and metal signs have appointed The Canadian Fairbanks-Morse Co., their representatives in Canada.

Motor Cars for Australia.—D. H. Ross, Canadian Trade Commissioner at Melbourne, Australia, points out that there is an exceptional opportunity at the present time for Canadian manufacturers of motor cars to secure reliable and energetic representation.

Regina, Sask.—The Saskatchewan Co-operative Elevator Co., are to build 30 new elevators this season at various points and six have been already completed. Including the 30 new elevators, there will be 260 in operation next fall as against 47 in 1911.

Motor Patrol Service.—A school of instruction for candidates for the Royal Naval Auxiliary Patrol Service is being opened in the Jarvis Building, 103 Bay Street, Toronto. Captain Stinson, of the Canada Steamship Lines, is instructor,

and a nominal fee will be charged for the course.

Orillia, Ont.—Orillia Water, Light and Power Commission has announced a further reduction in rates for electric lighting, varying from 7½ to 15 per cent. The reduction applies to both flat and meter rates, and commercial and domestic services, and is effective forthwith.

M. Beatty & Sons, Ltd., Welland, Ont., have been awarded a contract by the Dominion Bridge Co. for two hoisting engines and two vertical boilers, for use at the Intercolonial Railway Car Ferry Terminals, Carleton Point, P.E.I., and Cape Tormentine, N.B.

M Beatty & Sons, Ltd., Welland, Ont., have been awarded a contract by the St. Maurice Construction Co., for the supply of an 8 by 12 triple drum hoisting engine with boom swinger, and one 37 h.p. double drum electric hoist for use on the construction of the St. Maurice River Dam near Sanmaur, Que,

Small Fire at Scotia.—A small fire, damaging the roof of one of the departments of the Nova Scotia Steel & Coal Co., at New Glasgow, occurred on the morning of June 18. The damage was only slight and is fully covered by insurance. Little or no interference with the plant operation resulted.

The Prescott Emery Wheel Co., of Prescott, Ont., has obtained a new charter and will be known in future as the Prescott Mfg. Co. The Company has taken over new premises which will be remodeled and extended for making all kinds of emery and carborundum wheels by vitrified silicate process, and the "Crescent" brand for saws.

Will Make Shells at C.N.E.—Complete shells will be manufactured in the Process building at the Canadian National Exhibition, Toronto. Negotiations have been under way for some time between Dr. Orr and the Government with this end in view, and the consent of the Department of Militia has at last been reluctantly given for an exposition of the methods employed in turning out munitions for the Allies, from the rough forging to the finished article.

Electric Steel in Australia.—The installation of electric furnaces in each of the six capitals of Australia for making cast steel out of scrap is reported. The enterprise is backed by a company, who will erect the first plant in Sydney, the second in Melbourne, and the third in Perth. The furnace is said to be a Swedish type, and an English metallurgist will superintend the plants. The possibilities of such a process are considered excellent, since Australia imports 8,000 to 10,000 tons of steel per year.

Armstrong, Whitworth Board.—At a meeting of the Board of Armstrong, Whitworth of Canada, Ltd., held recently in London, England, H. B. Walker, local manager of the Canadian Bank of Commerce and president of the Montreal Board of Trade, was added to the directorate, as a third Canadian director. The board is made up as follows: President, Sir Edouard Percy C. Girouard; vice-president, George G. Foster, K.C.; directors, Hon. Sir George Herbert Murray, H. H. Smith-Carrington and H. B. Walker; director and general manager, Matthews J. Butler, C.M.G.

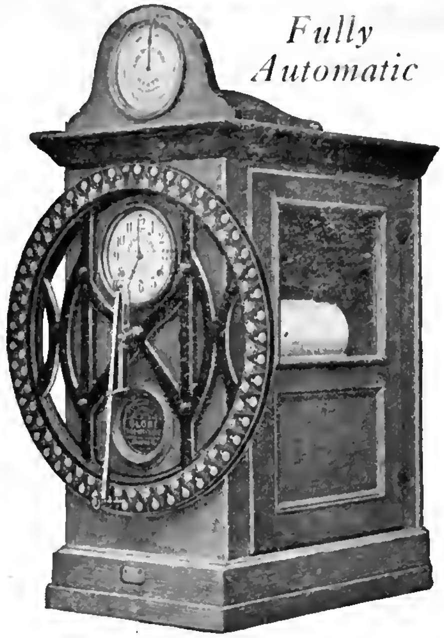
Importing Houses in India.—The Commercial Intelligence Branch of the Department of Trade and Commerce has received from H. R. MacMillan, Special Timber Trade Commissioner of Canada, lists of firms in British India, Burma and Ceylon importing the following articles:—Wood-working machinery; logging equipment; sawmill machinery; Douglas fir; box shooks; shooks for tea chests; doors; bobbins; newsprint for Ceylon. The lists also contain the names of Government officers who are considering the development of Burmese hardwood forests by railways. A copy of these lists will be furnished to any Canadian manufacturer who writes for it, referring to File A-1964.

Benzol Market Firm.—Signs of stiffening in the markets for sulphuric acid, benzol, toluol, and other explosive-making bases, are noticed. The improvement is attributed to the prospect of large orders for such materials being placed within the next few weeks. For some time the markets for these chemicals has been dormant, but of late a steady inflow of small orders has been reported. While no definite inquiries for large tonnages have appeared—except an unconfirmed report that the Dupont Company has closed a big new contract be true—the trade has been given reason to expect that Russia, France, and possibly Britain, will ask for bids on explosives and explosive ingredients in the near future.

McCharles Prize.—A thousand-dollar prize is offered for the second time this year by the Governors of the University of Toronto in recognition of discoveries or invtntions of special merit by Canadians. The prize is known as the McCharles Prize, and is awarded (1) to any Canadian who invents or discovers any new process for the treatment of Canadian ores or minerals after such process has been proved to be of special merit on a practical scale; (2) or for any important discovery, intention or device by any Canadian that will lessen the dangers and loss of life in connection with the use of electricity in suppling power and light; (3) or for any

"You Are Paying For It"

Fully Automatic



"What style of Time Recorder do you use?" asked one manufacturer of another.

"None," said the other, "the old way is good enough for me. I don't spend a cent on them."

"You don't, eh," said the first. "Well, we've tried both ways, and it's a safe bet you're paying for one right now just because you haven't got it."

International Time Recorders

Play no favorites. Its records are automatic. Each man makes his own record and cannot dispute it.

You need pay attention only to the RED figures when making up payrolls—all others are full time.

In face of competition you cannot afford to be without this great and only MECHANICAL check on the labor-time you buy.

It's as fair to the employee as it is to the employer.

Our Service Department

We maintain a Service Department at our factory that is at the call of our users at any minute. This Department employs only expert mechanics, thoroughly trained in the mechanism of all our Recorders. We urge our customers to have their Time Recorders inspected at regular intervals—as no piece of mechanism is proof against abuse.

marked public distinction achieved by any Canadian in scientific research.

Threshers in Argentina.—Argentina imported 1,000 threshing machines in the year ended March 31, 1916. The 1915 statistics show a total importation of only 627 threshers, although this was 546 more than in 1914, but many machines ordered to thresh the great wheat crop of 1915 were delayed in arrival by the irregularity of the steamship service, and when they reached Argentine ports in the late winter and the spring of 1916 the immediate need for threshers was largely past, for threshing in Argentina begins in December and is over by March or April. La Razon, of Buenos Aires, in a recent issue, calls attention to the large stock of threshers now available in Argentina, and believes it will be sufficient to thresh the wheat of the coming harvest.—United States Commerce Reports.

Personal

Major T. M. McAvity, of St. John, N.B., has been awarded the Distinguished Conduct Medal.

Richard James, Power Building, Montreal, has secured the Quebec agency of E. C. Humphreys Co., Detroit, Mich., for their pig iron, metals, coke, sand, and clay products.

H. B. Walker, manager the Canadian Bank of Commerce, and president the Montreal Board of Trade, has been elected a director of the Armstrong, Whitworth Co. of Canada.

C. C. Ballantyne, Montreal, vice-president and managing director of the Sherwin-Williams Co. of Canada, becomes Lieut.-Colonel, and will organize the 245th Battalion for overseas service.

W. R. Gilmore, Manager of the Canadian Steel Foundries, Welland, Ont., is resigning to become vice-president and general manager of a steel Company at Benton Harbor, Mich.

W. H. Horwood has been promoted to the position of sales manager with the Canadian Stee' Foundries. **F. E. Smith**, formerly sales manager, is now general superintendent of the plants at Longue Pointe, Point St. Charles, Montreal, and Welland, Ont.

George L. Sprague, of New York, a technical expert, is to be the new principal of the Technical School at Hamilton, Ont., with a salary of $4,000 a year. He was born in Belleville, Ont., and for a time was apprentice supervisor of the American Locomotive Co., and later of the Allis-Chalmers Co. in Milwaukee, Wis.

Sir Edgar R. Bowring, head of the British steamship firm of Bowring & Co., arrived at New York, June 23, on board the White Star liner Adriatic. Among his other engagements while on this side of the Atlantic will be a visit to Canada on business connected with his steamship interests. Asked as to his views on a possible early break in ocean rates, he expressed the opinion that the easing of the freight market recently noted was due to a readjustment of Government controlled cargoes and ships, tending to better systematize the handling of the numerous imports England is receiving from the British Colonies and the United States.

Contracts Awarded

Campbellford, Ont.—A contract has been let to T. McMannus for the construction of the new paper mill here. The main building will be 330 ft. by 38 ft.

Ottawa, Ont.—A contract has been awarded by the Department of Public Works, Ottawa, to Roger Miller & Sons, Toronto, for lock gates and equipment at East River Locks.

St. John, N.B.—The Maritime Dredging & Construction Co. has been awarded the contract for the erection of a second retaining wall and for reclamation work in the new dock area at West St. John.

Building Notes

Sudbury, Ont.—A new public school will be erected on college street. Full information may be obtained from the architect Victor L. Morgan of Sudbury.

Toronto, Ont.—Plans for the new Customs House and examining warehouse which is to be erected on the south-east corner of Yonge and Front streets have been prepared. The building will cover slightly over one acre of ground. It will extend for a distance of 238 feet on Yonge street and 212 feet on Front street, and will be of steel and concrete construction, seven storeys high.

Tenders

Toronto, Ont.—Tenders will be received by the chairman, Board of Control, City Hall, up to July 4, for the supply and delivery of one tank car asphalt, flux oil, for asphalt plant. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont. — Tenders will be received by the Chairman Board of Con-

trol, City Hall, up to July 4, for the supply and delivery of 4-in. stop valves for High Level Pumping Station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders will be received by the Board of Control up to July 4, for the supply and delivery of one 8-in. water-meter. Specification and form of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Tenders will be received up to July 4 for the supply of one 3-h.p. motor, one 20-inch square base self-feed vertical drill with ¾-inch drill chuck and shafting. Samples of the several articles can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide Street Fire Hall, Toronto.

Prince George, B. C. — Tenders for power plant equipment for the City of Prince George, B.C., will be received at the office of the city clerk, up to July 8, 1916. Specifications and instructions may be obtained at the office of the city clerk, or at the office of the consulting engineers, DuCane, Dutcher & Co., Rogers Bldg., Vancouver, B.C.

Welland, Ont.—Tenders for repairs to the southerly end of elevator mooring dock at Port Colborne, Welland Canal, will be received until July 14. Specification and form of contract to be entered into can be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the superintending engineer, St. Catharines, Ont.

Toronto, Ont.—Tenders for Examining Warehouse will be received until July 17. Plans, specification and form of contract can be seen and forms of tender obtained at the offices of Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., R. L. Deschamps, Central Post-office, Montreal, P.Q., and at the Dept. of Public Works, Ottawa.

Ottawa, Ont. — Tenders will be received until July 10 for 163,500 lbs. of galvanized iron telegraph wire, delivered at Montreal, Que., or 128,500 lbs. of same delivered at Kamloops, B.C., and 35,000 lbs. delivered at Vancouver, B.C.; early dates of delivery desired. Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa; also at the office of J. T. Phelan, superintendent of Government Telegraphs at Vancouver, B.C.

Ottawa, Ont.—Tenders will be received up to July 4 for the construction of reinforced concrete foundations on wood piles or concrete piles, for 1,000,000 bushel storage capacity grain elevator, working house and track shed at Transcona, Man., separate tenders to be submitted for the foundations with concrete piles and foundations with wooden piles, and tenders may be submitted on either or both designs. Plans, specifications, etc., may be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Chief Engineers, Moncton, N.B.; at the office of the General Superintendent, Winnipeg, Man.; at the office of the Resident Engineer, Fort William, Ont., and at the office of the J. S. Metcalf Co., engineers, Montreal, P.Q.

Railways - Bridges

Brantford, Ont.—The Lake Erie and Northern Railway station will be a one-storey structure, 76 ft. x 30 ft. red brick with stone trimmings.

Toronto, Ont.—The York County Council propose building a new bridge over the Humber River at Bloor Street at an approximate cost of $25,000.

C.P.R. Extending Lines.—This year the Canadian Pacific Railway has decided to complete the gap of seven miles from Vantage, on the Empress line, south of Moose Jaw, and connecting west of Weyburn at Assiniboia. Vice-president Grant Hall also announces that the line now in operation for 75 miles east of Stirling, Alta., to Fourways, will be extended 10 miles to Manyberries this year.

MACHINE TOOLS

Lathes, Boring Mills, Grinders, Every Make and Description of MACHINE TOOLS!

We give below a few samples:—

LATHES.

Three 16 x 8' Pratt & Whitney, Q.C.G., C.R., H.S., taper attachment, each $1000
One 16 x 8' Pratt & Whitney, C.R., taper attachment 1250

PLANERS.

72" x 72" Fitchburg, with 2 heads 1500
52" x 52" x 24' Betts, with 2 heads 1500
38" x 38" x 16' Pond, 2 heads, heavy duty 2000
42" x 15' Gleason, heavy pattern, adjustable housing, max. distance between the housings 56", 2 heads 1500
36" x 36" x 8' Gray, single head, motor-driven 1250
The above machine, belt-driven 1000
Two (2) 36" x 36" x 8' very heavy Powell with 2 heads, all steel gearing, arranged for motor or belt drive, weight 2,000 lbs., suitable for heavy forging work, each 1250
36" x 36" x 10' Sellers, latest pattern, 2 heads 2000
36" Detrick & Harvey Open Side Planer, 13' table 2000
Pease 24" x 24" x 6', one head 450

HORIZONTAL BORING MACHINES.

Lucas Horizontal Boring Machine 2000
Espen Lucas Floor Boring Machine, 4" bar, 40" travel, bores to centre of 12', 72" vertical travel, saddle on column 2750
Betts, Horizontal, 4" bar, 36" automatic feed, bores to centre of 60" 1500

RADIAL DRILLS.

4' Western, Full Universal, good as new 900
3' Harrington, plain 250
3½' Lambert, plain 200
42" Baush, latest pattern, heavy type 500
4' Dreses, motor-driven, with tapping attach 650
5' Pond 750
5½' Niles, semi-Universal 925

GRINDERS.

Landis, plain, capacity 8 x 42" 1400
Landis, No. 11, plain, capacity 7 x 36" 1250
Brown & Sharpe Universal, capacity 12 x 30" 1400
Springfield Universal, 16 x 40" 850
Two No. 5 Rivet, large assortment of collets, each 550

METAL CUTTING SAWS.

8" Higley 250
No. 2 Newton with 24" inserted tooth saw blade 400
Newton Cold Saw, takes 28" saw, 48" travel of saw carriage 600
Large Newton Cold Saw, takes 32" blade 750

TURRET LATHES.

No. 6 Brown & Sharpe, geared friction head, 1⅝" hole in spindle 500
18 x 6 Warner & Swasey, 2" H.S. 600
20 x 8 Beaman & Smith, back geared, with separate carriage 500
20 x 7 Lodge & Shipley, 2¼" H.S., geared friction head 650
21" Bogert, back-geared, friction head, 2½" H.S. 650
Jones & Lamson 2 x 24 Flat Turret, geared friction head 850
22½" Reed, geared friction head, 2" H.S. 675
Two (2) Potter & Johnson, full automatic chucking machines, geared head, fully enclosed, each 1000

VERTICAL BORING MILLS.

42" Baush, 2 heads, motor drive 1350
51" Bullard, 2 heads, motor drive 1750
54" Betts, single head 500
84" Pond, heavy pattern, 2 heads 2700

AUTOMATIC SCREW MACHINES.

Three (3) No. 2 Brown & Sharpe, each 500
Three (3) 2¼" Gridley Single Spindle, motor driven, each 1500
National Acme, 4-spindle, 3-16" 1250

MILLING MACHINES.

No. 5-B Becker Horizontal, plain 1250
No. 5 Garvin, plain 1000
No. 2 Beaman & Smith, one vertical and one horizontal spindle 2000

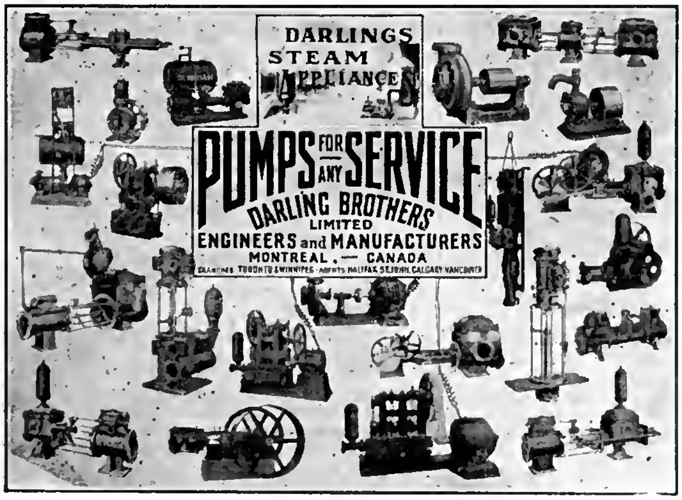
Montreal Factory: Aurora, Ont. Toronto

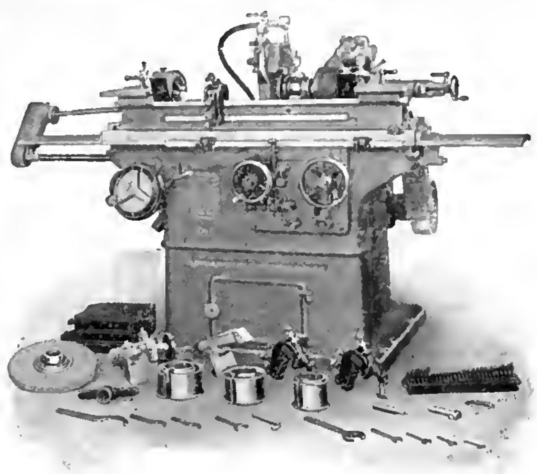
GEARS AND GEAR CUTTING SPROCKETS AND CHAINS

In stock and to order any size from one-quarter inch to six-foot in diameter, any material. Estimates and gear advice cheerfully furnished.

Grant Gear Works, Inc., 151 Pearl St. Boston, Mass. U.S.A.

G. B. GRANT





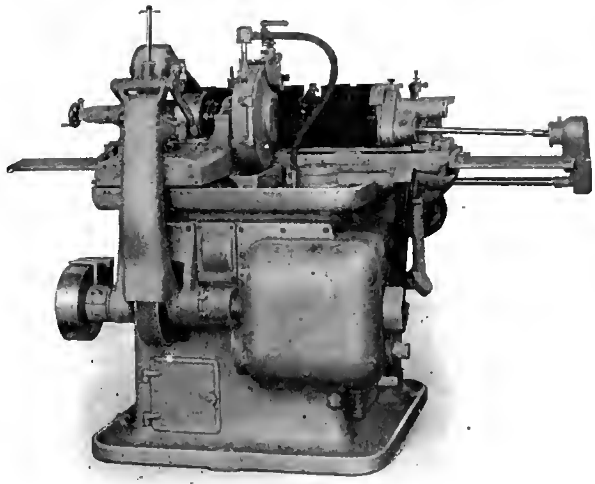
Here are two reasons why our new design *NOS. 10 and 11 PLAIN GRINDING MACHINES* will give you maximum production and economy.

Simple, Centralized Work Control

Just three levers grouped around a dial. One instantly stops and starts work and table travel together. The other two regulate work speed and table travel. Moving them around the dial like controller handles, while work is running, causes speed or traverse to increase or decrease, not by jumps, but steadily. The multiple friction disk mechanism gives a finely graduated range so that any feed and speed combination desired is instantly available.

Single Pulley, Constant Speed Drive

Complicated overhead works eliminated. Use a constant speed motor attached to machine base for driving if desired. All speed and feed changes are within machine. It is thus compact and not difficult to arrange for on shop floor. Wheel speed changes made by means of split spindle pulleys changed without shifting belt. Capacities of machine, 6" x 20", and 6" x 32". May we send an illustrated circular describing the many cost-cutting features?



Brown & Sharpe Mfg. Co.

PROVIDENCE, R.I., U.S.A.

Manufacturers of Milling Machines, Grinding Machines, Screw Machines, Gear Cutting Machines, Test Tools, Machinists' Tools, Cutters.

OIL AND WASTE RECLAIMING MACHINES
D'Olier Centrifugal Pump & Machine Co., Philadelphia, Pa.

ORNAMENTAL BRASS, BRONZE AND STEEL WORK
Newman Mfg. Co., Cincinnati, Ohio.

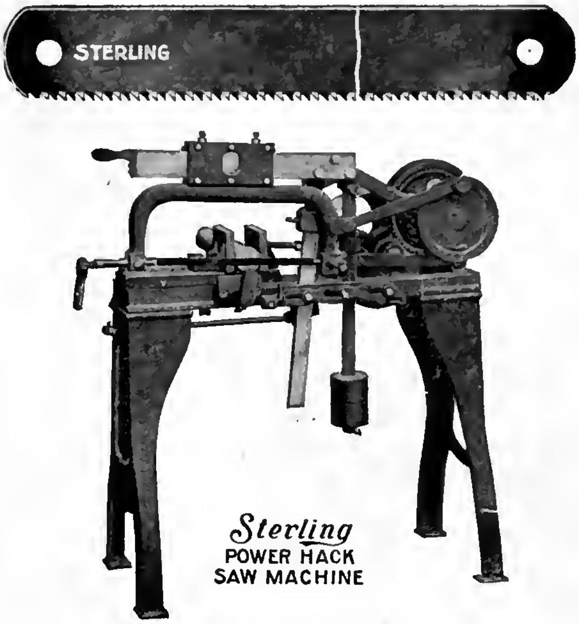
Don't Keep It--Sell It!

If you have a lathe
a drill
a milling machine
a planer
a chain block
a chuck
a motor
a crane
a stock of belting
an engine
a compressor
or any other machine shop equipment for which you really have no further use, why not turn it into *cash?*

Someone may be looking for just the machine you may want to sell. Let us bring you together.

A "classified" ad. in CANADIAN MACHINERY, costing a few cents per issue, has done wonders for others. Why not try it?

"STERLING" HACK SAWS



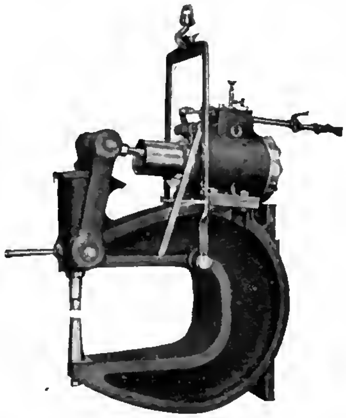
MANUFACTURED BY

DIAMOND SAW & STAMPING WORKS

BUFFALO, N.Y., U.S.A.

ALLEN Portable Pneumatic RIVETER

will give you the *Fastest* and *Tightest* Riveting at the Lowest Cost.



Special riveters designed to meet all requirements.

Send for Illustrated Catalogue.

Also Manufacturers of High-grade Coal Handling and Hoisting Machinery.

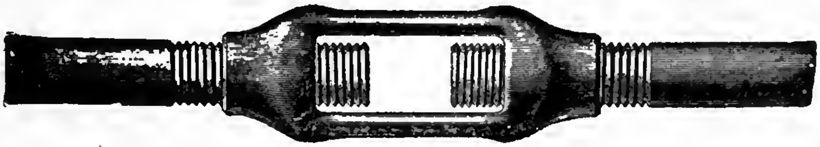
JOHN F. ALLEN COMPANY, (Established 1872)

370-372 Gerard Avenue, NEW YORK, U.S.A.

Liebers and W. U. Codes, "Riveter."

AGENTS—**Canadian Ingersoll-Rand Co., Ltd.,** Toronto, Ont.; Montreal, Que.; Winnipeg, Man.; Vancouver, B.C.; Sydney, N.S.; Cobalt, Ont.; Lethbridge, Alta.; Nelson, B.C.; So. Porcupine

Plyers, Structural Wrenches, Track Wrenches, Machine Wrenches, Eye Bolts, Lathe Dogs, Journal Box Wedges, Etc.



B
TRADE MARK

TAPPING MACHINES (PNEUMATIC)
Cleveland Pneumatic Tool Co. of Canada, Toronto.

TAPPING MACHINES AND ATTACHMENTS
John Bertram & Sons Co., Dundas.
Canada Machinery Corp., Galt, Ont.
Garvin Machine Co., New York.
The Geometric Tool Co., New Haven.
Greenfield Tap & Die Corporation, Greenfield, Mass.
J. H. Hall & Sons, Brantford, Ont.
A. B. Jardine & Co., Hespeler.
Landis Machine Co., Waynesboro, Pa.
Manufacturers Equipment Co., Chicago, Ill.
Modern Tool Co., Erie, Pa.
Murchey Machine & Tool Co., Detroit.
Niles-Bement-Pond Co., New York.
H. W. Petrie, Toronto.
Rickert-Shafer Co., Erie, Pa.
L. S. Starrett Co., Athol, Mass.

TAP CHUCKS
Wells Bros., Greenfield, Mass.

TAPS, ADJUSTABLE
Geometric Tool Co., New Haven.
Manufacturers Equipment Co., Chicago, Ill.
Murchey Machine & Tool Co., Detroit.

TAPS, COLLAPSIBLE
Geometric Tool Co., New Haven, Conn.
Manufacturers Equipment Co., Chicago, Ill.
Modern Tool Co., Erie, Pa.
Murchey Machine & Tool Co., Detroit, Mich.

TAPS, DIES AND WRENCHES
Butterfield & Co., Rock Island, Que.
Can. Fairbanks-Morse Co., Montreal
Can. Tap & Die Co., Galt, Ont.
Cleveland Twist Drill Co., Cleveland.
Foss & Hill Machy. Co., Montreal.
Geometric Tool Co., New Haven, Conn.
A. B. Jardine & Co., Hespeler.
Morse Twist Drill & Machine Co., New Bedford.
Murchey Machine & Tool Co., Detroit.
H. W. Petrie, Toronto.
Pratt & Whitney Co., Dundas, Ont.
L. S. Starrett Co., Athol, Mass.
Wells Brothers Co., Greenfield, Mass.

TECHNICAL BOOKS
The MacLean Publishing Co., Ltd., Toronto.

TESTING INSTRUMENTS, METALLURGICAL
Shore Instrument & Mfg. Co., New York City.

TESTING LABORATORIES
Can. Inspection & Testing Laboratories, Ltd., Montreal.
Toronto Testing Laboratory, Toronto.

THREAD-CUTTING MACHINES
Can. Fairbanks-Morse Co., Montreal.
Garvin Machine Co., New York.
Geometric Tool Co., New Haven, Conn.
Landis Machine Co., Waynesboro, Pa.
H. W. Petrie, Toronto.
Pratt & Whitney Co., Dundas, Ont.
National Machy. Co., Tiffin, Ohio.

THREADING MACHINES FOR SHELL PLUGS
Brown Engineering Corp., Toronto.

TIME CLOCKS
International Time Recording Co., Toronto.

TINSMITHS' TOOLS
Brown, Boggs & Co., Hamilton, Can.
Steel Bending Brake Works, Ltd., Chatham, Ont.

TIRE SETTING MACHINES, HYDRAULIC
William R. Perrin, Ltd., Toronto.
West Tire Setter Co., Rochester, N.Y.

TIRE, WHEELS
Wells Bros. Co., Greenfield, Mass.

TOOL HOLDERS
Aikenhead Hardware Co., Toronto, Ont.
Armstrong Bros. Tool Co., Chicago.
Cleveland Twist Drill Co., Cleveland.
Modern Tool Co., Erie, Pa.
Pratt & Whitney Co., Dundas, Ont.
J. H. Williams Co., Brooklyn, N.Y.

TOOL POSTS, LATHE
Armstrong Bros. Tool Co., Chicago.

TOOL ROOM PARTITIONS
Can. Wire & Iron Goods Co., Hamilton.

TOOL STEEL
Aikenhead Hardware Co., Toronto, Ont.
Armstrong, Whitworth, Ltd., of Canada, Montreal.
Can. Fairbanks-Morse Co., Montreal.
H. A. Drury Co., Montreal.
Hawkridge Bros. Co., Boston, Mass.
H. W. Petrie, Toronto.
Vanadium-Alloys Steel Co., Pittsburgh, Pa.
Vulcan Crucible Steel Co., Aliquippa, Pa.
Young, Corley & Dolan, Inc., New York, N.Y.

TOOLS, BLACKSMITHS', ETC.
A. R. Williams Machy. Co., Toronto.

TOOLS, ELECTRIC
Independent Pneumatic Tool Co., Chicago, Ill.
Stow Mfg. Co., Binghamton, N.Y.
A. R. Williams Machy. Co., Toronto.
United States Elec. Tool Co., Cincinnati, O.

TOOLS, LATHE, PLANER AND SLOTTER
Armstrong Bros. Tool Co., Chicago.

TORCHES, STEEL
Armstrong, Whitworth of Canada, Ltd., Montreal.

TRACK SYSTEMS
Northern Crane Works, Walkerville.
Whiting Foundry Equipment Co., Harvey, Ill.

TRANSMISSION MACHINERY
American Pulley Co., Philadelphia, Pa.
A. R. Williams Machy. Co., Toronto.
Can. Fairbanks-Morse Co., Montreal.
Can. Drawn Steel Co., Hamilton, Ont.
Dodge Mfg. Co., Toronto, Ont.
Hamilton Gear & Mach. Co., Toronto.
Lyman Tube & Supply Co., Montreal, Que.
Main Belting Co., Montreal.
Morse Chain Co., Ithaca, N.Y.
H. W. Petrie, Toronto.
F. Reddaway & Co., Montreal.
The Smart-Turner Machine Co., Hamilton.

TRANSMISSION TOWERS
Curtis Pneumatic Machinery Co., St. Louis, Mo.
Northern Crane Works, Walkerville.
Tallman Brass & Metal Co., Hamilton.

TRUCKS, FACTORY, FREIGHT, ETC.
Canada Machinery Corp., Galt, Ont.
Chapman Double Ball Bearing Co., Toronto.
Whiting Foundry Equipment Co., Harvey, Ill.

TRUCKS, LUMBER AND KILN
Sheldons, Ltd., Galt, Ont.
Northern Crane Works, Walkerville.

TUMBLING BARRELS
Baird Machine Co., Bridgeport, Conn.
Northern Crane Works, Walkerville.
Whiting Foundry Equipment Co., Harvey, Ill.

TURNBUCKLES
Canadian Billings & Spencer, Ltd., Welland.

TURRET MACHINES
Brown & Sharpe Mfg. Co., Providence, R.I.
New Britain Machine Co., New Britain, Conn.
H. W. Petrie, Toronto.
Pratt & Whitney, Hartford, Conn.
Root & Van Dervoort Engineering Co., East Moline, Ill.
Turner Machine Co., Ltd., Danbury, Conn.
Warner & Swasey, Cleveland, O.

TURRETS, TOOL POST AND TAIL STOCK
Jenckes Mach. Co., Sherbrooke, Que.
McCrosky Reamer Co., Meadville, Pa.
Newman Mfg. Co., Cincinnati, Ohio.

TURBINE WATER WHEELS
Jenckes Mach. Co., Sherbrooke, Que.
Wm Kennedy & Sons, Ltd., Owen Sound, Ont.

UPSETTING AND BENDING MACHINERY
John Bertram & Sons Co., Dundas.
Brown, Boggs Co., Ltd., Hamilton, Canada.
Cook, Asa S., Co., Hartford, Conn.
A. B. Jardine & Co., Hespeler.
National Machy. Co., Tiffin, O.
Canada Machinery Corp., Galt, Ont.
Niles-Bement-Pond Co., New York.
H. W. Petrie, Toronto.
A. R. Williams Machy. Co., Toronto.

VACUUM PUMPS
Can. Blower & Forge Co., Berlin, Canada.
Smart-Turner Machine Co., Hamilton, Ont.

VALVE LEATHERS
Graton & Knight Mfg. Co., Montreal.

VALVE GRINDERS (PNEUMATIC)
Cleveland Pneumatic Tool Co. of Canada, Toronto

VALVES, FOOT
Smart-Turner Mach. Co., Hamilton.

VALVES, HYDRAULIC
Can. Boomer & Boschert Press Co., Montreal.
Charles F. Elmes Eng. Works, Chicago, Ill.

VALVES, BACK PRESSURE, STEAM
Sheldons, Limited, Galt.

VENTILATING APPARATUS
Can. Blower & Forge Co., Berlin, Ont.
Sheldons, Limited, Galt.
H. W. Petrie, Toronto.
A. R. Williams Machy. Co., Toronto.

VISES, BENCH
Aikenhead Hardware Co., Toronto, Ont.
Foss & Hill Machy. Co., Montreal.
New Britain Machine Co., New Britain, Conn.
H. W. Petrie, Toronto.

VISES, PIPE
Aikenhead Hardware Co., Toronto, Ont.
Armstrong Mfg. Company, Bridgeport, Conn.
Bignall & Keeler Mach. Works, Edwardsville, Ill.
Butterfield & Co., Rock Island, Que.
J. H. Williams Co., Brooklyn, N.Y.

VISES, PLANER AND SHAPER
Aikenhead Hardware Co., Toronto, Ont.
Skinner Chuck Co., New Britain, Conn.

WASHER MACHINES
National Machy. Co., Tiffin, Ohio.

WASHERS
Barnes, Wallace, Co., Bristol, Conn.
Graton & Knight Mfg. Co., Worcester, Mass.
London Bolt & Hinge Works, London, Ont.
Steel Co. of Canada, Ltd., Hamilton, Ont.

WATER CINDER MILLS
Whiting Foundry Equipment Co., Harvey, Ill.

WATER TOWERS
Toronto Iron Works, Ltd., Toronto.

WATER WHEELS
Wm. Kennedy & Sons, Ltd., Owen Sound, Ont.

WELDING MACHINES, ELECTRIC, ETC.
Tabor Mfg. Co., Philadelphia, Pa.

WELDING, WORK AND SUPPLIES (Autogenous and Oxy-Acetylene). SEE OXY-ACETYLENE

WHEELS, EMERY, CARBORUNDUM
Foss & Hill Machy. Co., Montreal.
H. W. Petrie, Toronto.

WINCHES
John H. Hall & Sons, Brantford.
Northern Crane Works, Walkerville.

WIRE COILING AND POINTING MACHINES
Baird Machine Co., Bridgeport, Conn.
F. B. Shuster Co., New Haven, Conn.

WIRE CLOTH AND PERFORATED METALS
Canada Wire & Iron Goods Co., Hamilton.
Dennis Wire & Iron Works Co., Ltd., London.

WIRE FORMING AND STAMPING MACHINERY
Brown, Boggs Co., Ltd., Hamilton, Canada.
F. B. Shuster Co., New Haven, Conn.
Baird Machine Co., Bridgeport, Conn.

WIRE NAILS
Parmenter & Bulloch Co., Gananoque.
Steel Co. of Canada, Ltd., Hamilton, Ont.

WIRE NAIL MACHINERY
National Machy. Co., Tiffin, Ohio
A. R. Williams Machy. Co., Toronto.

WIRE, RUBBER-COVERED
Lachapelle, J. D., & Co., Montreal.

WIRE, STEEL, BRASS, COPPER, BRONZE
Steel Co. of Canada, Ltd., Hamilton, Ont.

WIRE STRAIGHTENERS AND CUTTERS
Baird Machine Co., Bridgeport, Conn.
Brown, Boggs Co., Ltd., Hamilton, Canada.
F. B. Shuster Co., New Haven, Conn.

WOOD BORING MACHINES
Canada Machinery Corp., Galt, Ont.
Cleveland Pneumatic Tool Co. of Canada, Toronto.
Garlock-Walker Machinery Co., Toronto.
H. W. Petrie, Toronto.

WOODWORKING MACHINERY
Can. Blower & Forge Co., Berlin, Canada.
Canada Machinery Corp., Galt, Ont.
Can. Fairbanks-Morse Co., Montreal.
Garlock-Walker Machinery Co., Toronto.
New Britain Machine Co., New Britain, Conn.
Oliver Machy. Co., Grand Rapids, Mich.
H. W. Petrie, Toronto.
A. R. Williams Machy. Co., Toronto.

WOOD LATHES
Canada Machinery Corp., Galt, Ont.
Oliver Machy. Co., Grand Rapids, Mich.

WOOD TRIMMERS.
Oliver Machy. Co., Grand Rapids, Mich.

WRENCHES
Armstrong Bros. Tool Co., Chicago, Ill.
Butterfield & Co., Rock Island, Que.
Canadian Billings & Spencer, Ltd., Welland.
Keystone Mfg. Co., Buffalo, N.Y.
Wells Bros. Co., Greenfield, Mass.
Whitman & Barnes Mfg. Co., St. Catharines, Ont.
J. H. Williams Co., Brooklyn, N.Y.

WRENCHES, AUTOMOBILE NARROW JAW AND MONKEY
Bemis & Call Hardware & Tool Co., Springfield, Mass.
Whitman & Barnes Mfg. Co., St. Catharines, Ont.

WRENCHES, PIPE, MONKEY
Aikenhead Hardware Co., Toronto, Ont.
Bemis & Call Hardware & Tool Co., Springfield, Mass.
Whitman & Barnes Mfg. Co., St. Catharines, Ont.

WRENCHES, RATCHET AND BASIN
Bemis & Call Hardware & Tool Co., Springfield, Mass.
Keystone Mfg. Co., Buffalo, N.Y.
Whitman & Barnes Mfg. Co., St. Catharines, Ont.
